Xanthorrhiza or *Yellow-root* (*Shrub yellow-root*) is the rhizome and roots of *Xanthorrhiza apiifolia* L'Her. (*X. simplicissima* Marsh), the only species of the genus, a slender shrub of the Allegheny region, and extending from New York to Texas. It grows in rich woodlands, especially in mountainous districts and along river banks. The stems are clustered, 1 to 2 feet high, smooth, grayish, and annulate from the distant leaf-scars. The leaves are alternate, crowded at the ends of the branches, long-petiolate, pinnate, and have 3 or 5 ovate or lanceolate, cleft and toothed leaflets, with wedge-shaped bases. The yellow flowers are polygamous and in compound drooping racemes, appearing in early spring, and are followed by fruits consisting of several small 1-seeded follicles. The slender, crooked, and much-branched rhizome sometimes exceeds a metre in length and varies from 3 to 20 Mm. ($\frac{1}{8}$–$\frac{4}{5}$ In.) in thickness. It is sparingly beset, especially on the branches, with slender and brittle roots. The surface is longitudinally wrinkled and light yellow brown. Internally, both the thin bark and the rather brittle wood are bright yellow, the latter showing a distinct pith and medullary rays. The fracture is short-fibrous. The odor is slight but characteristic, the taste very bitter and somewhat astringent, resembling that of berberis. *Yellow-root* contains as its active constituents something less than 1 per cent. of at least 2 alkaloids, principally berberine. With these occur several resins, besides starch, gum, and ordinary plant-constituents. Its properties and uses are identical with those of BERBERIS, which see.

Coptis or *Gold-thread* (*Canker-root*, *Mouth-root*, E.; *Gelbe* or *Kleine Niesswurz*, G.; *Coptide*, Fr.) is the rhizome of *Coptis trifolia* (L.) Salisb. (*Helleborus t.*—L.; *H. trilobus* Lam.; *H. pumilus* Salisb.; *Isopyrum t.*—Britt.). The plant is abundant in deep, mossy woods, especially where somewhat damp, throughout Canada and the northeastern United States. It sends up, from elongated, slender, much-branched, often somewhat matted, golden-yellow rhizomes, tufts of long and slenderly petioled, 3-parted, evergreen leaves, the divisions broadly cuneate-obovate, crenately toothed or lobed, the teeth slightly pointed, the upper surface dark green and shining and strongly veined. With these leaves occur, in early summer, slender, 1-flowered scapes about 10 to 15 Cm. (4–6 In.) high. The flower is white, about 1.2 Cm. ($\frac{1}{2}$ In.) broad, and consists of 5 to 7 deciduous sepals, as many small and inconspicuous hollow petals, numerous stamens, and several distinct carpels, becoming beaked follicles in fruit. The drug

should consist only of the filiform, matted, golden-yellow rhizomes with their very small roots, unlike any other article that appears in commerce. Frequently, however, the entire herb is supplied. The odor is slight, the taste similar to that of *Berberis* and *Xanthorrhiza*. Through imperfect cleaning, the drug is apt to contain much earthy matter, producing an undue amount of ash, this not exceeding 5 per cent. in a good article. Gold-thread contains much berberine and a very small amount of a white crystalline alkaloid which has been called *coptine*, but concerning the identity of which nothing is known, except that it dissolves in concentrated sulphuric acid without color, becoming purple on warming. The properties of *Coptis* are those of the berberine-yielding group in general. It is largely used as a masticatory or mouth-wash for canker-sores, and as a gargle in various forms of sore throat.

The genus *Coptis* contains 8 or 10 species, all probably sharing its constituents and properties. In India, *C. Tecta* Wall. is largely used under the names *Chinese gold-thread*, *Mishnee bitter*, in Chinese *Hong-lau*, *Chyn-len*, or *Soulin*. It is specially valued as an application for various eye-inflammations. *C. anemonifolia* Sieb. et Zucc. is a Japanese species, used in China under the name *Oh-ren* and in Turkestan under the name *Mamiran*.

Several species of *Thalictrum* also contain berberine. *T. aquilegüfolium* L. is the Japanese *Arikka*; *T. rubellum* L. is the Chinese *Shing-ma*; *T. revolutum* DC. and *T. Mexicanum* DC. constitute the Mexican drug *Cozticpatli*.

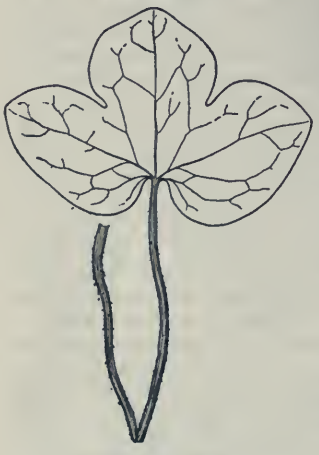
Actæa or *Baneberry* has been referred to in connection with CIMICIFUGA.

Pæonia or *Peony* is usually understood as the root of *Pæonia officinalis* L. (*Piny*, *Sheep-shearing rose*, E.; *Gicht-rose*, *Pfingstrose*, G.; *Pivoine*, Fr.; *Peonia*, Sp.), although most of the 15 species of the genus have been employed. This is the well-known red peony of the gardens, native of southern Europe. The roots are fleshy and starchy, irregularly fusiform, 5 to 10 Cm. (2–4 In.) long, and about 1.2 Cm. (½ In.) thick, the dark-brown bark usually removed from the commercial drug, which is then usually purplish or whitish, the fracture short, and showing short yellow wood-wedges. The drug has a strong and not very agreeable odor, as well as a distinct odor of bitter almond, and an acrid taste when fresh, but these are rapidly lost after drying. Fresh peony root probably contains oil of bitter almond, since Wigger obtained a distillate having that odor. Otherwise no special constituent has been encountered in it. The flowers and the seeds have also been employed.

Other Species.—*P. Moutan* Sims (*P. arborea* Don.), the *Tree-peony* (*Botan*, Jap.; *Mantan*, Chin.), contains a fat acid related to caprinic acid, crystalline, melting at 45° C. (113° F.), subliming at a higher temperature, and easily soluble in ether and alcohol. It also yields a volatile oil containing the crystalline body *pæonol*. This root is used in the Orient as an antispasmodic and emmenagogue. *P. rubra* Hort. is the Chinese carminative *Ch'ih-choh-yok*, *Ch'nen-choh*, or *Tian-chi*. *P. albiflora* Pall. (*P. edulis* Salisb.), and perhaps other species, yields an edible starchy root in Siberia, where it is known as *Peh-choh-yoh*. The seeds are used as a substitute for tea.

Hepatica or *Liverleaf*, incorrectly "Liverwort" (*Golden trifoil*, *Herb trinity*, *Ivy-flower*, E.; *Edelleberkraut*, *Leberblume*, G.; *Herbe de hepatique*, Fr.; *Hepatica*, Sp.), is the leaves of *H. Hepatica* (L.) Karst. (*Anemone Hepatica* L.; *H. triloba* Chaix.; *H. Americana* DC.; *H. nobilis* Moench), a low, acaulescent, evergreen herb occurring in woodlands almost throughout the north temperate zone. It grows from a dense cluster of fibrous roots, the rosette of leaves at first erect, at length becoming prostrate on long, villous petioles, the mature blades 5 to 7 Cm. (2–3 In.) broad, and nearly as long, cordate, deeply 3-lobed, the lobes oval-ovate, obtuse, entire, or the two lateral sometimes with a notch near the base, when young thin, light green and hairy, in age thick, smooth, deep green above, often purplish underneath, or even above. The flowers are solitary on scapes 10 to 15 Cm. (4–6 In.) long, range in color from deep blue to whitish, are 1.2 to 2 Cm. (½–¾ In.) broad, subtended by 3 ovate obtuse bracts which are shorter than the (mostly 4 to 8) colored sepals; petals wanting; stamens numerous, yellow; carpels several, distinct, becoming akenes in fruit. This is one of our very earliest and most pleasing spring flowers. The leaves lose about 70 to 75 per cent. in drying. The drug is nearly odorless and has a mucilaginous and slightly astringent taste. No analyst has succeeded in finding any constituent of importance. A little gum and tannin are the most noteworthy.

FIG. 335.



Hepatica (½ Nat.).

The northern and northwestern species, *H. acuta* (Pursh) Britton (*H. triloba acuta* Pursh; *H. acutiloba* DC.), has acute lobes.

Anemone, very closely related to both *Hepatica* and PULSATILLA, is a genus of nearly 100 species, a score of which are medicinally employed. They have acrid juices, similar to

that of Pulsatilla, with which they agree pretty well in constituents and properties. The drug *Anemone* (*Wood anemone, Wind-flower, Bow-bells,* E.; *Weisser Waldhahnenfuss,* G.; *Anêmone des bois* or *A. sylvie,* Fr.) is commonly understood as the fresh plant of *A. nemorosa* Mx., of Europe, or its American representative, *A. quinquefolia* L. (*A. nemorosa quinquefolia* A. Gray). These are low and delicate herbs, growing and blooming in earliest spring, in woodlands, from small fleshy, white rhizomes. The stem is simple, erect, slender, usually 10 to 20 Cm. (4–8 In.) high, and bears 3 petioled, 3- or 5-parted leaves close to the solitary, terminal flower, which is nearly 1 inch broad, white or purplish, and consists of (mostly 5) delicate sepals, numerous stamens, and several distinct carpels, becoming akenes in fruit. Later in the season the true leaves appear, these being radical, long-petioled, subrotund, and 5-parted. The principal constituent of the drug is *anemonin* (see PULSATILLA). The plant is poisonous like the last named, and its properties and uses are about the same.

Some pharmacopœias prefer it to pulsatilla.

Clematis is a genus of nearly 200 species, mostly herbaceous or soft-woody climbers, some 25 of which are recorded as in medicinal use. The drug, as commonly understood, is the herbage and flowers of *C. Virginiana* L., the *Virgin's* or *Ladies' bower, Love-vine, Traveller's-joy, Devil's-hair, Nigger's-wool,* or *Devil's darning-needle.* The fresh drug is said to be much more active. This is a soft-wooded shrub, climbing over fences, hedges, and bushes by means of the twisted petioles, and occurring throughout eastern and central North America. Leaf- and flower-habit are shown in the accompanying cut. The white flowers are diœcious and occur in abundance during middle and late summer, and are followed in the fall by dense white masses of the long-plumose akenes. The fresh herbage has a heavy odor and an acrid after-taste. The precise nature of its acrid constituent is unknown, but it occurs as an oily, volatile, irritating liquid.

C. recta L., the *Upright virgin's bower,* yielded the *Herba flammulæ jovis* of the ancients. *C. Vitalba* L. is the *European virgin's bower,* etc., *Gray-* or *Old-man's beard, White-vine, Snow-in-harvest, Smoke-weed.* Besides a volatile liquid, probably identical with that of the last-described drug, this has yielded a crystalline basic substance. *C. cirrhoza* L. is believed to be the *Clematis* of Dioscorides. *C. sericea* H. B. K., of tropical America, is the Mexican *Barbas de Chivo. C. triloba* Hayne is the East Indian *Laghu-karni* (Sansk.) or *Morwel.*

FIG. 336.

Clematis Virginiana: branch (½ Nat.); pistillate and staminate flowers (Nat.).

Ranunculus is a genus of some 250 species, mostly known commonly as *Buttercups.* Their juices are colorless and for the most part very acrid, on which account many of them have been employed more or less as counter-irritants, and *R. bulbosus* is a recognized drug. The general characters of the buttercups are too well known to require description. The species named is distinguished by the bulbous stem-base and the strongly reflexed sepals. It is of European nativity, but is abundantly naturalized in many parts of the United States. Its active constituent, as of the other species, is an irritant oily liquid, yielding anemonin; practically equivalent to that of *Pulsatilla.* It is an active blistering agent, but the blister, though but slightly painful, is very difficult to localize and control. Another species which has been considerably employed is *R. sceleratus* L., the *Cursed, Celery-leaved, Marsh, Ditch,* or *Biting crowfoot* or *Buttercup* or *Blisterwort,* a coarse, stout, rank-growing but small-flowered species growing in ditches, with thick, hollow, and weak stems. It has been used by beggars to create ugly-looking but little painful sores, designed to excite sympathy, whence one of its names, *Beggar's-weed.* In the Orient it is called *Kabikadisch.* These plants are violently poisonous when taken internally, and are believed to cause abortion when eaten by pregnant cattle.

RESINA, *U. S.*, *Br.*—Rosin.

Colophonium, P. G.—*Resin, Colophony*, E.; *Colophone, Arcanson*, Fr. Cod.; *Kolophonium, Geigenharz*, G.; *Pece Greca*, It.; *Colofonia, Pez griega, Brea seca*, Sp.; *Pez Lauri, Colophonie do commercio, Resina do Pinheiro*, Port.

The residue left after distilling off the volatile oil from turpentine. Official in all pharmacopœias.

Origin.—The origin of common rosin is sufficiently explained by the above definition and by our accounts of Terebinthina and Oleum Terebinthinæ.

Properties.—Rosin is a very brittle, pulverizable, transparent or translucent resin, having about the specific gravity 1.070–1.080, breaking with a glossy and shallow conchoidal fracture, nearly tasteless, and of a faint terebinthinate odor. It varies in color from a pale amber to a dark red brown, and is distinguished in commerce by the shade of its color, the darkest being called *black rosin*. For pharmaceutical purposes the amber-colored variety is used. *White rosin* is a light-colored variety, made by agitating the melted rosin with water. It dissolves readily in ether, chloroform, alkalies, benzene, carbon disulphide, and in the volatile and fixed oils; at 60° C. (140° F.) it is slowly soluble in its own weight of alcohol or of glacial acetic acid. It softens at the heat of a water-bath, melts completely above 100° C. (212° F.)—some varieties at about 135° C. (275° F.)—and at a higher heat burns with a dense yellow and sooty flame. When heated to above 200° C. (392° F.) it may be distilled apparently unchanged with a current of superheated steam, but on dry distillation it yields *rosin oil*.

Variation in the transparency of different lots of rosin depends upon the thoroughness of the distillation, the retention of a portion of the oil or of water. Variations in color depend upon the degree of heat employed or the condition of the trees yielding it. The virgin dip yields the lightest rosin, and the latter becomes darker with each succeeding year. It has been suggested that this is due to the fact that the later distillations are subjected to a greater degree of heat. Rosin is scarcely subject to adulteration.

Composition.—Rosin consists largely (80 to 90 per cent., Flückiger) of *abietic anhydride* ($C_{44}H_{62}O_4$), which, upon agitation with warm diluted alcohol, becomes *abietic acid* ($C_{44}H_{64}O_5$). The latter often occurs in irregular, glassy, crystalline points or white scales. Emmerling obtained it as a snow-white powder, by treating with strong ammonia-water, passing through muslin, and decomposing the resulting jelly-like mass with hydrochloric acid. Kelbe obtained it in long triclinic prisms by crystallizing it from glacial acetic acid. Statements concerning the melting-point are conflicting. The highest recorded (Maly) is 165° C. (329° F.). It is soluble in ether, chloroform, benzene, wood spirit, and carbon disulphide, and yields amorphous compounds with bases. The other constituents have not been determined. *Pinic* and *sylvic* acids have been reported, but it has been suggested that they are only impure abietic acid. Certainly, Shkateloff has proved that the corresponding acid of the resin of *Pinus sylvestris* has a different composition, though closely resembling the above in general characters. It is not unlikely that similar differences will be found in the composition of other coniferous resins.

Pharmaceutical Preparations.—Rosin Cerate, Compound Rosin Cerate, U. S. P.

Uses.—Resin is rarely given internally. It is added to ointments to render them stimulating and to plasters to increase their adhesiveness.

RESINA COPAL.—Copal.

This name has been indefinitely applied to a group of resins of widely different origin, but agreeing in general appearance, in being collected chiefly in a fossil state, and in being very hard and tough and specially adapted for the manufacture of varnishes. Botanically they form two principal groups: those pertaining to the *Leguminosæ*, which are the copals proper, and those pertaining to other families, the most important being *Kauri copal*, of the family *Pinaceæ* or *Coniferæ*.

Of the first-named group, the best and most important variety is *Zanzibar copal* or *Animi* (also called *Chakazzi copal*), produced by the large tree *Trachylobium Mozambicensis* K[1]., closely related, as are all of this group, to the trees yielding copaiba. The tree is a living one, and some resin is probably obtainable from living specimens; but it

is probably true here, as of others of the group, that resin thus collected is very inferior to that obtained from the ground in a fossil state. Little is known of the methods of collection, the resin being brought to the coast from the interior by natives. It is then "raw," encrusted with dirt and altered superficial resin, and has to be cleaned and scraped to prepare it for the market. It then presents itself in fragments ordinarily varying in size from a few pounds down to an ounce or so, but occasionally weighing a hundred pounds or more. It varies in color from pale yellow to deep red brown, and from beautifully transparent to opaque, except in thin fragments. The surface may be perfectly smooth and of subglossy lustre, longitudinally marked, as with wood-fibres, or warty with minute roundish projections, giving a "goose-flesh" appearance, such a surface being not shining. The last-mentioned sort is greatly preferred and brings a higher price. Animi is both hard and tough and of a splintery fracture, and has a specific gravity of about 1.04. Stephen describes it as follows: Melting, when finely powdered, at 140° C. (284° F.); completely though slowly soluble in alcohol; 30 per cent. soluble in benzol, chloroform, and glacial acetic acid; 34 per cent. in ether, 10 per cent. in petroleum spirit and carbon disulphide; on being boiled with alcohol it cakes, but by repeated digestion with alcohol all is dissolved, then precipitated with water, the precipitated resin soluble in boiling 0.1 per cent. solution of potash; not saponifiable; consists of 80 per cent. trachylolic acid, in minute sphero-crystalline masses melting at 168° C. (334.2° F.); 4 per cent. isotrachylolic acid; 6 per cent. α and β copal resins; volatile oil and bitter principle. The author regards it as a pathological product. Very similar resins come from Mozambique and Madagascar, the latter being probably produced by the closely related tree *Hymenæa verrucosa* Lam. From West Africa comes a copal supposed to be produced by one or more species of *Copaiba* (=*Guibourtia*). South American copal, usually very clear and light colored, and largely used by the natives for making ornaments, closely resembling those made of amber, is not very abundant in commerce. It is said to be produced by *Hymenæa Courbaril* L., *H. stilbocarpa* Hayne, *H. Martiana* Loc., and *Trachylobium Hornemanniana* Hayne. The writer has himself collected this resin upon the large pods of the first-named species.

Of the second class of Copals, *Kauri* (*Kowrie* or *Kari*) is by far the most important. It is often known as New Zealand Copal. This also is the product of a species still living, the *Kari* or *Kauri* tree, *Agathis australis* Rich. (*Dammara australis* Lamb.), but the resin of good quality is dug in a fossil condition, the collectors locating it by means of a sharpened steel rod thrust into the ground. The most of it comes from the district to the north of Auckland. It varies in size as does Animi. The fragments are more inclined to be massive—that is, less tabular and splintery—than are those of Animi. In color it varies from nearly white to nearly black. It is said to be darker when from swampy ground, and that from Walkato is the darkest. It is far less transparent than Animi, even the clear pieces exhibiting a sort of milkiness or opalescence in the interior. It is heavier than Animi (specific gravity about 1.11), but is not so hard. It can be softened between the teeth. Tschirch and Niederstadt give it the following composition: 1.5 per cent. *kaurinic acid* ($C_{10}H_{16}O_2$); 48 to 50 *α-* and *β-kaurolic acids* ($C_{17}H_{34}O_2$); 20 to 22 *kauronolic acid* ($C_{12}H_{24}O_2$); 12.5 volatile oil, about the same amount of resene, and 0.5 to 1 of bitter principle. All are amorphous except kaurinic acid, which is crystalline, and is separated by means of its solubility in ammonium carbonate solution. The kaurolic acids are dissolved out by sodium carbonate; kaurinic and kauronolic acids are soluble in potassium hydroxide solution. The essential oil has a pleasant balm- or lemon-like odor, and a specific gravity of 0.835 at 15° C. (59° F.) It boils between 150° and 160° C. (302° and 320° F.), the greater portion distilling between 156° and 160° C. (312.4° and 320° F.). It is soluble in all proportions in alcohol, chloroform, and ether. When first distilled, it is neutral in reaction, but becomes acid on exposure to the air in thin layers, and rapidly resinifies. Small quantities of a kind of copal are produced in the East Indies, differing from all of the foregoing, by the tree *Vateria Indica* L. (*Elæocarpus copalliferus* Retz.—Fam. *Dipterocarpaceæ*).

Resina Damar or *Dammar* is closely related to the last named, being produced by some species of *Shorea*, of the same family, in the East Indies. This resin is of totally different appearance from any of those described above. It occurs in rounded nodules or "tears," mostly of the size of an egg or smaller, the surface usually nodular or warty, and dull or powdery, and ranging in color from nearly white to pale-straw color. Its specific gravity is only about 1.08. It softens readily between the teeth and melts at about 120° C. (248° F.). It is softer than Kauri, breaks with a glassy fracture, is

odorless and tasteless, soluble in ether, chloroform, benzol, and carbon disulphide, less so in alcohol and benzin. Tschirch gives its composition as including 23 per cent. of crystalline *dammarolic acid* ($C_{56}H_{80}O_8$), 40 of *α-dammar resin* ($C_{11}H_{17}O$), 22.6 of *β-dammar-resin* ($C_{31}H_{52}O$).

Uses.—Copal is not used in medicine.

RESINA DRACONIS.—Dragon's Blood.

Sang-dragon, Fr. Cod.; *Drachenblut*, G.; *Sangre de drago*, Sp.

The resin obtained from the fruit of *Calamus Draco* Willd. (*Dæmonorops D.*—Blume) and probably from other species of *Calamus* (Fam. *Palmæ*).

Origin and Preparation.—This is a slender rattan palm of the East India islands, the stem extending sometimes for hundreds of feet, and climbing by hooks on the petiole and ribs of the leaf. The resin exudes and hardens in the form of small granules upon the surface of the scaly fruits, which are of the size and form of a pigeon's egg, and is shaken and brushed off. It is then made to cohere in masses by softening with the heat of the sun or hot water, and it is said to be invariably mixed with the milk-juice of a Garcinia, to increase the weight. It is sometimes molded into irregular small pellets or granules (*Tear dragon's-blood*), sometimes in balls or slabs, sometimes by hardening in small bags or saucers (all known as *Cake dragon's-blood*), but is most frequently seen in the American market in the *stick* form, the cylindrical sticks rather smaller than licorice extract sticks, each enclosed in a leaf and its surface more or less longitudinally marked by the impressions of the leaf-ribs. Owing to the article being chiefly used as a pigment, those lots having the brightest color are preferred, and the stick-form is generally regarded as inferior. The latter is said to be derived from a distinct species. Dragon's blood arrives in boxes containing from 100 to 500 pounds each.

Properties.—Dark red brown, internally brighter and occasionally brilliant red, somewhat porous, the fracture resinous but irregular, owing to mechanical impurities, transparent in very thin splinters; inodorous, but when heated yielding a slight benzoin odor, faintly sweetish and pulverulent on chewing; readily soluble in alcohol, amyl alcohol, benzene, and chloroform, less so in ether and oil of turpentine, insoluble in petroleum benzin.

Constituents.—Reports concerning the composition of dragon's blood are contradictory, due doubtless to the use of samples of different origin. That in which Trimble found 35 per cent. of oak tannin was doubtless entirely distinct from the one here considered, very likely from the *Pterocarpus draco*, mentioned below. Rather more than half of a good dragon's blood consists of a bright-red resin. Johnston's formula for this can hardly be constant, for Dieterich finds it to consist of benzoic and benzylacetic acids in combination with *dracoresinotannol*, although others have asserted that benzoic acid is not contained. Dieterich found 13.5 per cent. of *dracoresin* and 2.5 per cent. of the peculiar body *dracoalban*, which is white and non-crystallizable. There is a variable amount of impurities, as well as of ash, which in a good sample should not exceed 8 or 9 per cent. Harberger found 90.7 per cent. of the resin, which he called *draconin*, and for which he attempted to find a chemical formula. He also reported 3 per cent. of benzoic acid, 2 per cent. of fixed oil, and calcium oxalate and phosphate. The presence of the two last-named substances and of much volatile oil, as natural constituents of the resin, may be doubted without confirmation.

Action and Uses.—Dragon's blood was used in former times as a mild astringent in diarrhœa, but is now never given internally. It was formerly an ingredient of many plasters. At present it is used to impart a mahogany color to varnishes.

Other Varieties and Allied Products.—The genus *Calamus* contains some 200 species, most notable for their production of rattan and cane (*Malacca*) sticks. *C. niger* W. and *C. Scipionum* Lour. have been named as also yielding dragon's blood.

A kind of dragon's blood (really a *kino*) is yielded from incisions into the bark of *Pterocarpus Draco* L. (Fam. *Leguminosæ*), of the West Indies. The dragon's blood tree of the Canary Islands (*Dracæna Draco* L.—Fam. *Liliaceæ*) is notable for the existence of individuals supposed to be the oldest of living trees, and older probably than the history of the human race. Its product is said to be similar to that above described, but in the fresh state the juice is intensely acrid. *Socotrine* or Zanzibar dragon's blood ("*Katir*") has been regarded as the product of a related species, *D. Ombet* Kotschy, but this is now regarded as identical with *D. Draco*.

RESINA JALAPÆ, *U. S., P. G.*—Resin of Jalap.

Jalapæ resina, Br.—*Résine de jalap*, Fr.; *Jalapenharz*, G.

Preparation.—Jalap, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity. Moisten the powder with 300 Cc. of alcohol and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until 2500 Cc. of percolate are obtained or until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol by means of a water-bath until the percolate is reduced to 250 Gm., and add the latter, with constant stirring, to 3000 Cc. of water. When the precipitate has subsided decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of hot water. After having drained off all the liquid, transfer the resin to a porcelain dish and heat to dryness on a water-bath. —U. S.

These directions are about the same as in the former pharmacopœia. The alcoholic tincture of the jalap containing the resin in solution is concentrated by distillation, and this liquid while still warm poured into water, stirring continually, so as to bring nearly all particles of the resinous matter in direct contact with water, whereby the solution of those constituents which are soluble in water is facilitated. After repeated washings with fresh portions of water the resin is collected and dried. By this treatment water removes sugar and some other principles of jalap, which are also soluble in water, and which possess some medicinal activity.

The British Pharmacopœia directs 1 part of water for 2 parts of jalap to be added to the percolate, from which nearly the whole of the alcohol may be recovered by distillation. The residue while hot is poured into an open dish and allowed to cool, when the liquid portion is decanted, the resin washed several times with hot water, and dried.

The German Pharmacopœia directs the jalap to be exhausted by digestion with alcohol, the tincture to be concentrated, and the resinous residue to be repeatedly washed with warm water (boiling water, Fr. Cod., P. A.) as long as this takes up coloring-matter. The resin may also be obtained by depriving jalap of its principles soluble in hot water, drying and powdering the residue, and exhausting it with alcohol. Good jalap yields about 12 per cent. of resin (not less than 8 per cent., U. S.).

Properties and Tests.—Resin of jalap occurs in yellow to brown masses or fragments, breaking with a resinous, glossy fracture, translucent at the edges, or a yellowish-gray to yellowish-brown powder, having a slight, peculiar odor, and a somewhat acrid taste. Permanent in the air. Soluble in alcohol in all proportions; insoluble in carbon disulphide, benzene, and fixed or volatile oils. Its alcoholic solution has a faintly acid reaction to blue litmus-paper. Not more than 10 per cent. of resin of jalap should be soluble in ether, and not more than 35 per cent. in chloroform. Slowly but completely soluble in 5 times its weight of ammonia-water; when this solution is acidified with hydrochloric acid, only a slight turbidity should appear (absence of rosin, guaiac, and other resins). Resin of jalap should not suffer any material loss of weight when heated at 100° C. (212° F.) (absence of water). Anhydrous resin of jalap melts at about 150° C. (302° F.). Water triturated with resin of jalap should neither become colored nor dissolve any portion of it (absence of soluble impurities). No greenish-blue color should be produced on adding a few drops of ferric chloride test-solution to some of the powder moistened with alcohol (absence of guaiac). 1 Gm. of resin of jalap when dissolved in 50 Cc. of alcohol containing 1 Cc. of phenolphthalein test-solution should require not more than 0.5 Cc. of tenth-normal alcoholic potassium hydroxide solution to produce a red color (limit of acid resins). If to 1 Gm. of resin of jalap, dissolved in 50 Cc. of alcohol in a flask, 25 Cc. of tenth-normal alcoholic potassium hydroxide solution be added, and the mixture be heated on a water-bath for 1 hour, and if the excess of alkali be titrated with tenth-normal sulphuric acid solution, using 2 drops of phenolphthalein test-solution as indicator, the difference between the number of cubic centimeters of tenth-normal sulphuric acid solution required and the 25 Cc. of tenth-normal alcoholic potassium hydroxide solution taken should not exceed 5 Cc. (limit of saponifiable substances).—U. S. An adulteration with rosin may be detected by the solubility

in oil of turpentine, and the presence of aloes manifests itself by its bitter taste and the production of picric acid when treated with nitric acid. "1 part of resin of jalap should dissolve in 5 parts of warm ammonia-water; on cooling the solution should not gelatinize (absence of colophony), and should remain clear after being supersaturated with an acid."—P. G.

Pharmaceutical Preparations.—SAPO JALAPINUS, P. G.—*Jalap Soap*, E.; *Jalapenseife*, G.—Equal parts each of resin of jalap and medicinal (white Castile) soap, both in fine powder, are thoroughly mixed. This preparation is of a brown-yellow color, is soluble in alcohol, and yields with about 10 parts of water a nearly clear solution, which becomes somewhat cloudy, but does not separate any resin.

PILULÆ JALAPÆ, P. G.—Mix jalap soap 3 parts and powdered jalap root 1 part. Each pill is to weigh 0.10 Gm. and to be dusted with lycopodium.

COMPOUND CATHARTIC PILLS, VEGETABLE CATHARTIC PILLS, U. S. P.

Action and Uses.—Since this resin contains practically all the purgative principles of jalap, it may be substituted for the crude drug. The dose is from 2 to 5 grains (0.12–0.30 Gm.) when used alone. Combined with other cathartics it may be given in smaller dose.

RESINA PODOPHYLLI, *U. S.*—Resin of Podophyllum.

Podophylli resina, Br.; *Podophyllinum*, P. G.—*Resin of May-apple*, E.; *Résine de podophyllum*, Fr.; *Podophyllin, Podophyllumharz*, G.; *Podofilina*, Sp.

Preparation.—Podophyllum, in No. 60 powder, 1000 Gm.; hydrochloric acid, 10 Cc.; alcohol, water, each a sufficient quantity. Moisten the powder with 480 Cc. of alcohol and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until 1600 Cc. of percolate are obtained, or until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol by means of a water-bath until the percolate is reduced to the consistence of a thin syrup, and pour it slowly, with constant stirring, into 1000 Cc. of water, previously cooled to a temperature below 10° C. (50° F.), and mixed with the hydrochloric acid. When the precipitate has subsided decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of cold water. Spread it in a thin layer upon a strainer, and dry the resin by exposure to the air in a cool place protected from the light. Should it coalesce during the drying or aggregate into lumps having a varnish-like surface, it should be removed, broken in pieces, and rubbed in a mortar.—U. S.

The low temperature directed in the precipitation and drying is the chief distinction from the process of the British Pharmacopœia, which permits the resin to be dried on a stove.

On pouring the concentrated tincture of podophyllum into acidulated water the extractive matters remain in solution while the resin is precipitated. The addition of hydrochloric acid appears to exert no action on the product, and to be useful merely in hastening the deposition of the resin from the aqueous liquid. Both the British and French pharmacopœias omit the hydrochloric acid. The yield is between 4 and 5 per cent. of the weight of podophyllum used; by exhausting the rhizome with alcohol of specific gravity 0.930, G. H. C. Klie (1877) claimed to have obtained as much as 7¼ per cent.

Properties and Tests.—An amorphous powder, varying in color from grayish white to pale greenish yellow, turning darker when subjected to a heat exceeding 35° C. (95° F.) or when exposed to light. It has a slight, peculiar odor and a faintly bitter taste; very irritating to the mucous membrane, especially to that of the eyes. Soluble in alcohol in all proportions; not less than 75 per cent. of resin of podophyllum should be soluble in ether, not less than 65 per cent. in chloroform and not more than 25 per cent. in boiling water. A hot, aqueous solution deposits most of its contents on cooling, and if the cooled liquid be filtered, the filtrate has a bitter taste, and turns brown upon the addition of a few drops of ferric chloride test-solution. Soluble in potassium or sodium hydroxide test-solution, forming a deep yellow liquid, which gradually becomes

darker on standing, and from which the resin is reprecipitated by acids. Not less than 99 per cent. of resin of podophyllum should be soluble in alcohol; the solution should be clear or, at most, slightly opalescent, and should have a faintly acid reaction. Upon incineration, resin of podophyllum should yield not more than 0.7 per cent. of ash.—U. S. According to Power, podophyllum resin becomes soft at 120° C. (248° F.), and is completely melted at 124° C. (255° F.). Sulphuric acid colors it intensely yellow, the color changing to purplish and to brown on the addition of a trace of nitric acid. Among the oxidation products by nitric acid are oxalic acid and an amorphous yellow substance.

Composition.—F. B. Power (1877) observed that the largest portion of the resin consists of at least four compounds, differing in their solubility in ether and hot water and in their behavior to alkalies, ferric chloride, and lead acetate; fused with potassa, *protocatechuic acid* was obtained, but no resorcin. The official resin contains also a little fatty matter, and yields a small proportion of ash, consisting chiefly of sodium and potassium salts. Podwissotzki (1880) obtained from podophyllum resin yellow needles resembling quercetin, a green oil, a crystalline fat acid, podophyllic acid (without activity, soluble in hot water), and two poisonous principles: one of these, *podophyllotoxin*, is obtained from the concentrated chloroform solution by treating it with benzin, which will remove the oil and fat acid; it has the composition $C_{23}H_{24}O_9$ (Kürsten, 1891), crystallizes from benzene, is white, very bitter, faintly acid, sparingly soluble in water, and by treatment with ammonia yields podophyllic acid and *picropodophyllin*. The latter is intensely bitter, freely soluble in chloroform, ether, and, according to Kürsten, has the same composition and yields the same decomposition products as podophyllotoxin, but is more sparingly soluble.

Gordin and Merrell have proposed a method for the valuation of commercial resin of podophyllum, based upon its podophyllotoxin content, which involves the conversion of the latter constituent into picropodophyllin by means of calcium hydroxide. In view of the fact that resin of podophyllum is often found of inferior quality on the market, these authors claim that it should yield at least 22 per cent. of crude picropodophyllin when assayed by the method which they propose. (See *Proc. Amer. Pharm. Assoc.*, 1902, p. 343 *et seq.*)

Action and Uses.—This resin, commonly called podophyllin, is given in the dose of from $\frac{1}{20}$ to $\frac{1}{10}$ grain (0.003–0.006 Gm.) as a laxative, $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.) as a purge (see PODOPHYLLUM).

RESINA SCAMMONII, *U. S.*—Resin of Scammony.

Scammoniæ resina, Br.; *Résine de scammonée*, Fr. Cod.; *Scammoniaharz*, G.; *Resina de escamónea*, Sp.

Preparation.—Take of scammony, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity. Digest the scammony with successive portions of boiling alcohol until exhausted. Mix the liquids, filter, and reduce the mixture to a syrupy consistence by distilling off the alcohol. Then add the residue in a thin stream, with active stirring, to 2500 Cc. of water, separate the precipitate formed, wash it thoroughly with water, and dry it with a gentle heat.—U. S.

Take of scammony root, in coarse powder, 8 ounces (150 Gm.), alcohol (90 per cent.), distilled water, of each a sufficient quantity. Exhaust the scammony root with the alcohol by percolation; place the resulting tincture in a still; recover the greater part of the alcohol; slowly pour the liquid which remains after the distillation of the tincture into three times its volume of the distilled water, constantly stirring; allow the mixture to stand for the resin to subside; then wash the resin on a filter with boiling water, distilled water, and dry it on a water-bath.—Br.

Prof. Markoe (1877) showed that the alcoholic extract of scammony yields to water only 2 per cent. of soluble matter, which is removed by washing, as directed in the first formula. The French Codex directs an alcoholic solution of scammony to be treated with animal charcoal for the purpose of removing most of the coloring-matter; after filtration the alcohol is recovered by distillation and the resulting resin dried on plates in a warm room. The yield of resin varies with the quality of scammony employed.

Properties and Tests.—Resin of scammony occurs in yellowish-brown or brownish-yellow masses or fragments, breaking with a glossy resinous fracture, translucent at

the edges; or a yellowish-white or grayish-white powder, having a faint, characteristic odor, and a slight, peculiar taste. Soluble in alcohol in all proportions, completely soluble in oil of turpentine, and almost completely soluble in ether and chloroform. Ammonia-water and solutions of alkalies dissolve it with the aid of a gentle heat, and from these solutions the resin is not reprecipitated by acids. When incinerated, it should not yield more than 1 per cent. of ash. Sulphuric acid, when stirred in a porcelain dish with an equal weight of resin of scammony, should not gradually turn red (absence of rosin).—U. S.

Action and Uses.—This resin represents the medical properties of scammony and is about twice the strength of the crude drug. It is rarely administered alone, but in combination with other cathartic drugs. Because of its insipid taste it may be readily administered to children, usually made into an emulsion with milk or mucilage and sweetened. The dose as an active purge for adults is from 5 to 15 grains (0.30–1 Gm.).

RESORCINOL, *U. S.*—Resorcinol.

Resorcinum, P. G.; U. S., 1890.—*Résorcine*, Fr. Cod.; *Resorcin, Metadioxybenzene, Metadihydroxybenzene*, E.; *Résorcine*, Fr.; *Resorcin*, G.; *Resorcina*, Sp.

Formula, $C_6H_6O_2$ or $C_6H_4(OH)_2$. Molecular weight, 109.22.

A diatomic phenol obtained usually by the reaction of fused sodium hydroxide upon sodium metabenzene-disulphonate. Resorcinol should be kept in dark amber-colored vials.—U. S.

Origin.—Resorcinol was discovered by Hlasiwetz and Barth (1864) on melting galbanum, ammoniac, or guaiacum resin with potassa. It is produced in a similar manner from asafetida, sagapenum, ascaroid resin, and from phenol-sulphonic acid and other derivatives of phenol; likewise on the dry distillation of extract of Brazil-wood.

Preparation.—Resorcinol is now manufactured on a large scale from benzene. The latter is heated with about 4 times its weight of fuming sulphuric acid to 275° C. (527° F.), whereby benzene metadisulphonic acid is formed ($C_6H_4(HSO_3)_2$). When cool the acid is dissolved in water and neutralized with milk of lime; after removal of calcium sulphate by means of a filter-press, sodium carbonate is added, the mixture again filtered, and the solution of sodium benzene-metadisulphonate evaporated to dryness. The sodium salt thus obtained is heated for 8 or 9 hours at 270° C. (518° F.) with 2½ times its weight of caustic soda, sodium-resorcin, $C_6H_4(ONa)_2$ being formed, together with sodium sulphite. Continued boiling of a solution of the saline mass expels the sulphurous acid, and the tar-like residue is then extracted with ether, which latter, upon distillation, leaves impure resorcin. By sublimation or recrystallization from water or benzene pure resorcinol is obtained.

Properties and Tests.—Resorcinol occurs in colorless, needle-shaped crystals, having a faint, peculiar odor, and a sweetish, followed by a bitter taste. It acquires a pinkish tint on exposure to light and air. It is soluble in 0.5 part of water at 25° C. (77° F.), slightly more soluble in alcohol; very soluble in boiling water or in boiling alcohol; also readily soluble in ether and glycerin; very slightly soluble in chloroform, carbon disulphide, and benzene. When heated to 119° C. (246.2° F.) resorcinol melts, and at a higher temperature is completely volatilized. It boils at 276.5° C. (529.7° F.), and is slightly volatile in a current of steam. The aqueous solution is neutral or only slightly acid to litmus-paper. On adding a few drops of ferric chloride test-solution to 10 Cc. of an aqueous solution of resorcinol (1 in 200) the liquid assumes a bluish-violet color, changing to brownish yellow on the addition of ammonia-water (distinction from catechol and quinol). Lead acetate test-solution should produce no precipitate when added to an aqueous solution of resorcinol (distinction from, and absence of, catechol). If 0.1 Gm. of resorcinol be dissolved in 1 Cc. of potassium hydroxide test-solution and a drop of chloroform added, the mixture upon being heated will assume an intense crimson color. If a slight excess of hydrochloric acid be then added, the color will change to a pale straw yellow. On cautiously heating 0.05 Gm. of resorcinol with 0.1 Gm. of tartaric acid and 10 drops of concentrated sulphuric acid, a thick carmine-red liquid will be formed, becoming pale yellow when diluted with water. A concentrated aqueous solution of resorcinol (1 in 20) should be colorless (absence of empyreumatic bodies), and when gently heated should not emit the odor of phenol.—U. S. Resorcinol precipitates metallic silver from ammoniacal solution of silver nitrate. Its solution in ammonia when

exposed to the air turns rose red and brown, and, when heated, green and blue, this color being changed to red by acids. The aqueous solution of resorcinol yields with bromine-water needles of tribromresorcin, $C_6Br_3H(OH)_2$. Resorcinol carefully fused with sodium nitrite yields *lacmoid*, a blue coloring-matter similar to litmus. To detect small quantities of resorcin a few drops of nitric acid containing nitrous acid are added to an ether solution of the resorcinol. On standing, *diazoresorcin* crystallizes out. The crystals yield a blue solution with ammonia (Hager).

When carefully heated in a test-tube, resorcinol should melt to a clear colorless liquid; on increasing the heat it should volatilize, producing white vapors, and leaving no residue, or merely a minute amount of charcoal. Heated in a porcelain or platinum dish, it should volatilize without residue.

Chemically, resorcinol is a dihydroxybenzene, of which three varieties have been obtained, named, respectively, ortho- meta-, and para-dioxybenzene; the first is known as catechol or pyrocatechin, the second as resorcinol or resorcin, and the third as hydroquinol.

Unfortunately, the name resorcinol has (1893) also been applied to a compound obtained by heating to the point of fusion a mixture of equal parts of resorcin and iodoform; it is an amorphous coffee-colored substance of an iodine-like odor and disagreeable taste.

Resorcinol is used as the basis for the manufacture of a number of important dyes, *resorcin-blue*, -brown, -green, -purple, resorcin-phthalein, and the commercial *fluorescein* and *eosines*.

Action and Uses.—Resorcinol possesses antiseptic properties resembling those of phenol. It arrests decomposition of organic substances, deodorizes, and prevents putrefactive changes by destruction of the organisms upon which they depend. Applied to the unbroken skin it does not irritate and is not absorbed, but in substance or saturated solution it acts as a mild caustic to mucous membranes or ulcerations of the integument.

The caustic property is not exhibited in weaker solutions.

In animals, lethal doses cause at first trembling, soon followed by epileptiform convulsions, probably of spinal origin, which increase in severity until the animal is too weak to respond to spinal irritation.

Respiration at first accelerated, becomes jerky, rapid, and shallow, death being due largely to respiratory depression.

The heart becomes rapid, irregular, and gradually weaker, continuing to beat, however, after respiration has ceased.

Resorcinol has rarely been the cause of death in man. The ingestion of 150 grains of it was followed by dizziness, confused vision, deafness, and vertigo; presently loss of consciousness supervened, and epileptiform convulsions and tetanic rigidity of the muscles of the neck occurred. Respiration was greatly embarrassed and cardiac action hurried and enfeebled. The individual recovered.

Administered in large medicinal doses (20 to 40 grains—1.3–2.6 Gm.) to fever patients resorcinol brings about a lowering of temperature, probably from the profuse sweating produced, and it also reduces the rate of the pulse, but the headache, dizziness, and other unpleasant symptoms which it causes are responsible for its disuse as an antipyretic.

It is eliminated largely by the urine and may be detected by the addition of ferric chloride, which produces a violet color.

In gastric ulcer, gastralgia, catarrh of the stomach, and fermentative dyspepsia, resorcin has been recommended as an efficient remedy, but the results of its employment for these conditions have not been uniform or satisfactory, and it is rarely given. It is employed chiefly for its antiseptic and local anæsthetic virtues in the treatment of skin diseases, particularly those of subacute or chronic character, as eczema, when the skin is greatly indurated, psoriasis, seborrhœa capitis of the dry and scaly type, parasitic diseases, as tinea and scabies. It is applied either in solution containing 10 to 20 grains (0.60–1.30 Gm.) to the ounce (30 Cc.) of water, to which a little glycerin is usually added, or in ointment of the strength of ½ to 1 drachm (2–4 Gm.) to the ounce (30 Gm.). In powder or saturated ethereal solution it is sometimes efficient in the treatment of sluggish syphilitic and non-specific ulcerations. In 1 to 3 per cent. solutions it may be applied as spray or irrigation in catarrhal and ulcerating inflammations of the nasal, aural, pharyngeal, bladder, or uterine mucous membranes.

The dose is from 2 to 5 grains (0.12–0.30 Gm.).

Allied and Derivative Compounds.—CATECHOL.—*Pyrocatechin, Orthodioxybenzene.*—This, the third of the group of isomerides having the general formula $C_6H_4(OH)_2$, is contained among the products of the destructive distillation of several tannins and vegetable extracts; it may also be obtained by fusing orthophenolsulphonic acid with caustic potassa for some time at 320° to 360° C. (608°–680° F.); but the best process for manufacturing it is to heat guaiacol to 195° to 200° C. (383°–392° F.), and then passing in hydriodic acid as long as methyliodide distils over. Catechol occurs in acicular crystals or prisms, readily soluble in water, alcohol, ether, and hot toluene, melting at 104° C. (219.2° F.) and boiling at 245° C. (473° F.). With ferric chloride it strikes an emerald-green color which, on addition of sodium bicarbonate, is changed to a beautiful violet red. Catechol dissolves in solutions of alkali hydroxides to brown or black solution. It is a strong reducing agent, reducing silver nitrate in the cold and Fehling's Solution on warming. Pyrocatechin has been used as an antipyretic, but is a dangerous remedy.

HYDROQUINOL.—*Hydroquinone, Hydrochinone, Paradioxybenzene.*—This isomer of resorcin was discovered by Wöhler (1844). It may be obtained by the dry distillation of kinic, succinic, and oxysalicylic acids, but is usually prepared by oxidation of aniline with potassium dichromate and sulphuric acid, and subsequent reduction of the quinone formed by sulphurous acid. Hydroquinol forms long colorless and odorless dimorphous crystals, which have a sweetish taste and melt at 169° C. (336.2° F.). It is soluble in about 17 parts of water at 15° C. (59° F.), and very soluble in hot water, alcohol, and ether. With ferric chloride hydroquinol in strong solution yields green quinhydrone, or, if the iron be added in excess, yellow quinone; these reactions distinguish it from resorcin. Hydrochinone resembles resorcin in its properties, but is more powerful. Large doses cause disturbed cerebration, unconsciousness, convulsions, marked cardiac and circulatory depression, and distinct lowering of body-temperature. Like other drugs which simply lower febrile temperature without shortening the course or diminishing the severity of the disease, its use as an antipyretic has been abandoned. It is eliminated by the urine, to which it imparts a greenish-brown color. It is extensively employed in photography as a developer. The dose is from 10 to 20 grains (0.6–1.30 Gm.).

EURESOL.—*Resorcinmonacetate, Monacetylresorcin.* $C_6H_4(OH)CH_3CO_2$.—Euresol is prepared by heating resorcin with acetic anhydride. It is a yellowish, transparent, syrupy mass having an agreeable odor. It is soluble in acetone. It boils at 283° C. (541.4° F.).

FLUORESCEIN, or *Anhydride of Resorcinolphthalein,* $C_{20}H_{15}O_5$, is obtained by fusing together 7 parts of resorcin and 5 parts of phthalic anhydride; it occurs as yellowish-red to dark-brown crystals, which form with ammonia a red solution, exhibiting a beautiful green fluorescence. Fluorescin is difficultly soluble in water, ether, and benzene. It is soluble in alcohol with yellowish-red color and strong yellowish-green fluorescence, perceptible in solutions apparently colorless by transmitted light. Recommended for the diagnosis of corneal lesions and detection of minute foreign bodies imbedded in that tissue. When aqueous solution is dropped upon the cornea, those parts, however small, which are deprived of their epithelium are colored green, while foreign bodies are surrounded by a green ring (Straub).

RESOPYRINE.—When 30 parts of antipyrine and 11 parts of resorcin, each dissolved in three times its weight of water, are mixed, a crystalline mass separates, which upon resolution in alcohol may be obtained in rhombic crystals. To this compound the name resopyrine has been given. It is odorless and has a faintly pungent taste; insoluble in water, but soluble in 5 parts of alcohol, 30 parts of chloroform, or 100 parts of ether. It differs chemically from resorcin in not forming a precipitate with lead subacetate nor a blue color with ferric chloride.

THIORESORCIN, $C_6H_4O_2S_2$, is a yellowish non-crystallizing powder, readily soluble in solutions of the alkali hydroxides, carbonates, and sulphides, but insoluble in other solvents. It is obtained by heating 1 molecule of resorcin with 3 molecules each of sulphur and sodium hydroxide, with addition of water until solution results; upon acidulating the solution, amorphous yellow flocculi separate, which may be purified by resolution in alkalies and subsequent addition of acid. Thioresorcin has been applied as a substitute for iodoform, but its use was followed by unpleasant symptoms.

RHAMNUS PURSHIANA, *U. S.*—Cascara Sagrada.

Cascara Sagrada, Br., Fr. Cod.—*Chittim-wood bark, Sacred bark,* E.

The dried bark of *Rhamnus Purshiana* DC. (Fam. *Rhamnaceæ*), collected at least 1 year before being used.—U. S.

Cascara Sagrada is official in all the more important pharmacopœias, except the German.

The plant is a large shrub or small tree inhabiting the northwestern United States and adjacent British America, extending south to northern California. The dried quills of bark are now mostly broken up and packed tightly under pressure before being marketed.

Description.—In short quills, mostly 1 to 2.5 Cm. ($\frac{1}{2}$–1 In.) in diameter, or in curved pieces of the same, about 2 to 5 Mm. ($\frac{1}{12}$–$\frac{1}{5}$ In.) thick; outer surface purplish or reddish brown, usually more or less, often completely, covered with grayish or whitish lichens, shallow, wrinkled, and fissured, but never distinctly rough, except in the root-bark; inner surface at first yellowish, becoming darker, and at length of a very dark or blackish brown with keeping, very finely short-striate; fracture short, sharp, and granular, dark red in the outermost, light yellow in the middle, and darker yellow in the inner layers, the last mentioned showing shortly projecting yellow bast-fibres; under the microscope the transverse section exhibits the medullary rays with their outer ends regularly curved together to form dome-shaped groups; odor characteristic, aromatic; taste bitter, slightly aromatic.

When the medullary rays are irregularly curved and grouped, the bark is not of this species.

Adulterants and Substitutes.—This bark was formerly substituted largely by that of *Rhamnus Californica* Esch., a small shrub growing in clumps in California and southeastward. Indeed, there is some reason to believe that the latter was the bark first introduced under the name Cascara Sagrada. Its collection has now entirely ceased. It is in smaller quills, and they are inclined to be of a duller gray, with less purplish red upon the surface. The medullary-ray characters are indicated at the close of the above description. In the powdered condition, Frangula is apt to be substituted or admixed. If the former, stone-cells will be wanting; if the latter, the stone-cells are fewer and the longer bast-fibres of Frangula are to be seen. The Swiss Pharmacopœia mentions that the 1 per cent. decoction of R. Purshiana is merely slightly darkened by ammonia, while that of Frangula is deeply colored. The parenchymatous elements of Cascara Sagrada are colored yellow by chlorinated potash, while those of Frangula are colored deep red.

FIG. 337.

Rhamnus Purshiana (branch, ½ Nat.; bark, Nat.).

FIG. 338.

Rhamnus Californica (½ Nat.).

Constituents.—Cascara sagrada contains much resin and emodin, a small amount of a body that is apparently iso-emodin, about 2 per cent. of tannin, glucose, fixed oil, a little strongly odorous yellow-green volatile oil, rhamnol (apparently identical with quebrachol), a non-laxative hydrolytic enzyme, and a substance yielding syringic acid on treatment with acids. The ash-yield is about 7 per cent. Much effort has been devoted to isolating the active constituent, which Cabannes locates in the layers of bast immediately adjoining the cambium, and in the medullary rays of that layer, but without success. Jowett, who in 1904 made an exhaustive experimental review of the work of preceding investigators, showed that the "cascarine" and "purshianin," reported by them, were impure emodin, and that the emodin is not active. Purshianin probably contains the active constituent, as it was found laxative in $\frac{1}{5}$-grain doses. The active principle is probably a derivative of a glucoside present in the bark, but this is not experimentally proved. Jowett found that the alcoholic extract, extracted with water,

precipitated with lead subacetate, and this precipitate extracted with ethyl-acetate, yielded a non-crystalline, sticky mass which contained the active principle.

Pharmaceutical Preparations.—Extract of Rhamnus Purshiana, Fluidextract of Rhamnus Purshiana, Aromatic Fluidextract of Rhamnus Purshiana, U. S. P.

Action and Uses.—Cascara sagrada is considered to be the best drug we have for habitual constipation due to functional inactivity of the intestine or lack of digestive secretions. It not only increases the secretions of the gastro-intestinal canal, but because of its bitterness acts as a tonic, improves the appetite and digestion, and prevents the constipation which usually follows the use of similar drugs. So marked are the tonic effects of cascara that its dose may be gradually diminished and its use finally discontinued without return of the constipation.

It should never be given as a purge, only as a laxative. It operates usually without causing pain or discomfort, producing semi-solid stools. Cascara tends in some persons to produce hemorrhoids if given over a long period of time. Cascara is usually given in a single dose at night, frequently morning and night. The *aromatic* fluidextract in the dose of 10 to 30 minims (0.60–2 Cc.) is preferred on account of its pleasant taste. The ordinary fluidextract, given in the same dose, has quite a bitter taste, which is difficult to mask. The dose of the solid extract is from 2 to 8 grains (0.12–0.50 Gm.). Larger doses than these may produce irritation of the bowel and intestinal catarrh.

Other Species of Rhamnus.—The genus contains some 70 species, and most of those barks which have been tested were found to possess laxative properties. A number of these are so employed, notably those of *R. alnifolia* L'Her., the *Alder-leaved* or *Dwarf buckthorn*, and of *R. Caroliniana* Walt., of the southeastern United States, the *Southern*, *Carolina*, or *Alder buckthorn*, *Bog birch*, or *Indian cherry*.

Rhamnus cathartica L. (*Cervispina c.*—Moench), of central and southern Europe and adjacent Africa and Asia, the *Purging* or *Hart's buckthorn*, *Rain-* or *Rhineberry* (*Kreuzdorn*, *Hirschdorn*, G.; *Naprun purgatif*, Fr.; *Espina Cerval*, *Ramno Catartico*, Sp.), yields a drug of these names, consisting of the nearly ripe fruits, *Fructus* or *Baccæ rhamni catharticæ* or *Spinæ cervinæ*). The plant is a much and densely branched shrub of thickets, its small branchlets spinose. The dried fruit is globose, about 3 Mm. (⅛ In.) in diameter, strongly wrinkled, and slightly grooved between the seeds; of a dull greenish-gray color. It is seated in a persistent, usually 4-lobed calyx, attached to a slender pedicel about twice the length of the fruit. A small disk is interposed between the calyx and the fruit, the latter consisting of a thin sarcocarp enclosing (usually 4) 1-seeded nutlets, the putamen parchment-like. It has a slight, disagreeable odor, increased on soaking, and a nauseous and bitter taste, and tinges the saliva yellow. Tschirch and Polace isolated 3 yellow coloring-matters, *rhamnocitrin*, *rhamnolutin*, and *rhamnochrysin*. *Rhamnonigrin* is a glucoside yielding chrysominic acid, or, boiled with potassa, emodin. Emodin is also present, apparently identical with that of Frangula, together with sugar, pectin, gum, fat, and a bitter principle. Aside from its medicinal use, this fruit has been employed in dyeing, as have those of *R. infectoria* L. (*French berries*, E.; *Gelbbeeren*, G.; *Graines d'Avignon*, Fr.), which are more brown in color and mostly 2- or 3-grooved and -seeded. *Persian berries* are the somewhat similar fruits of *R. aleoides* L. (*R. amygdalina* Desf., and probably other species. A *Chinese green indigo* is said to be yielded by the fruits of several Asiatic species.

Fig. 339.

Rhamnus cathartica (× 2).

Rhamnaceæ (*The Buckthorn Family*).—This peculiar and somewhat incongruous family comprises, according to Weberbauer, 46 genera and nearly 500 species. It is very difficult to generalize concerning its properties, but it may be said that while one group of species is noted for its laxative or cathartic properties, as above explained, another, represented by *Ceanothus* (see under Krameria), is distinguished by its astringency. As in the case of that plant, so the leaves of *Sageretia theazans* (L.) Brongn. (*Rhammus t.*—L.) are used in China as a substitute for tea. Quite a number of edible fruits are yielded by the genera *Zizyphus* and *Hovenia*. Several of the former are known as *Jujuba*, or *Jujube berries* (*Brustbeeren*, *Judendornbeeren*, G.; *Jujube*, Fr.; *Azufayfas*, Sp.), and were formerly quite an important article of trade. They are produced chiefly in the Mediterranean region, from large spiny shrubs on small trees, both wild and cultivated. The fruits are oval, from 1.25 Cm. (½ In.) to nearly 2.5 Cm. (1 In.) long, bright-red, smooth and shining when fresh, drying brownish and much wrinkled, drupaceous in structure, containing 1 or 2 stones. The pericarp is sweet and mucilaginous.

The wood of *Colletia spinosa* Lam. (*C. horrida* Willd.), of tropical America, is purgative and contains the amaroid or glucoside *colletin*, as probably do several other species of the same regions. The bark of *Discaria febrifuga* Mart., of Brazil, has been used as a cinchona-sub-

stitute. The fruit *Tapura Guianensis* Aubl. is used in Guiana as a fish-poison. The same is true in Mexico of the bark of *Gouania tomentosa* Jacq. (called *Barbasco* or *Castilla de vaca blanca*). It contains saponin and is used in catarrh and otherwise medicinally.

Chewstick is the stem of *Gouania Domingensis* L., chewed by the natives as a sialagogue, stomachic, and carminative, and also credited with disinfectant properties, and used in gonorrhœa. In the same districts, the bark (*Mabee bark*) of *Colubrina reclinata* Brongn., containing a glucoside, is also used as a stomachic.

RHEUM, *U. S.*—Rhubarb.

Rhei radix, Br.; *Radix rhei*, P. G.—*Radix rhubarbi*, Dan., Russ.; *Radix rheorum*, Nor.; *Rhubarb-root*, E.; *Rhubarbe*, Fr.; *Rhabarber*, G.; *Ruibarbo*, Sp.; *Rhuibarbo*, Port.; *Rabarboro*, It.

The dried rhizome of *Rheum officinale* Baillon, *Rheum palmatum* L., and the variety *tanguticum* Maxim., or probably of other species of *Rheum* (Fam. *Polygonaceæ*), deprived of most of the bark and carefully dried.

All pharmacopœias agree in referring this drug wholly or in part to *R. officinale*. Quite a number name also *R. palmatum*. The Dutch and Russian mention *var. tanguticum* Maxim. of the latter species.

Origin.—All genuine Rhubarb used in this country is Chinese rhubarb, in the sense that it is produced in northwestern China or the region near it. Other varieties will be considered at the close of this article. One of the genuine Chinese rhubarb plants is cultivated to some extent in England, but the rhizome is small and commercially inferior and is wholly consumed at home. Turkish or Russian rhubarb is now a name only. Formerly, as a result of treaty arrangements, the very choicest of the Chinese product was exported *via* Russia or Turkey, its selection being controlled by the Russian government, so that there was technically a Turkish or Russian variety, but this arrangement long ago ceased to exist. The best grades of Chinese rhubarb are the Tze-chuen and Shensi products. The great bulk is known commercially as Canton, though this name has gradually ceased to be correct as a designation of geographical origin. These varieties are distinguished chiefly by their "bouquet" or odor, and the inexperienced can scarcely hope to identify them by means of any description. In China, the Hsining product is regarded as much the choicest.

The rhubarb plants possess the same general appearance as that of ordinary garden rhubarb or pie-plant. The leaves and stem proceed from a very thick and fleshy, short, vertical rhizome or "crown," from which a number of thick roots commonly branch. It is dug in the fall, the roots removed, the corky layer peeled off, and the larger rhizomes frequently sliced to facilitate drying. The larger roots are also preserved, though regarded as inferior and commonly known commercially as "tails." The pieces thus trimmed are commonly perforated and hung upon strings for drying. This process is tedious, requiring many weeks, and the article meantime is subject to various dangers. If the process be perfectly conducted, a drug of fine smooth surface and delightful fragrance results. Frequently the producer prefers a surer or more rapid process, and resorts to drying in kilns or ovens, this product being known commercially as "high dried." Such rhubarb bears broad grooves, alternating with ridges, upon its surface, a blackish color commonly existing in at least some of the grooves. Its odor is heavy, rank, and slightly empyreumatic.

Rhubarb is very subject to insect-attack, best prevented by keeping in the tightly closed container a tuft of cotton saturated with chloroform.

Description.—Rhubarb occurs in cylindraceous, somewhat tapering or barrel-shaped pieces, mostly 5 to 12 Cm. (2–5 In.) long and about half as thick, or in vertical halves or slices of the same, the latter usually representing larger rhizomes. The former is known as "round" rhubarb and is commonly preferred to the latter, which is called "flat." The rounded surfaces are mostly slightly angular, evidently as a result of peeling, bright yellow and powdery, the yellow powder being easily rubbed off, when the reddish or brownish medullary rays and intersecting intermediate bands of grayish parenchyma can be seen forming a fine network upon the surface. The odor is peculiar and pleasantly fragrant, the taste bitter, astringent, mucilaginous, and somewhat aromatic, and a decidedly gritty sensation is produced upon chewing, the saliva being colored yellow. Rhubarb is hard and rather heavy. The fracture is irregular and its surface more or less reticulated by the medullary rays. On transverse view, the direction of the medullary rays is seen to be very irregular. The rays

are of a reddish-brown color, running through a grayish parenchymatic tissue. The fibro-vascular bundles are usually present, in the rhizomes only, in a more or less continuous circle near the periphery, and each possesses a peculiar and rather pretty stellate form. In structure, they possess the peculiarity of having their xylem tissue external to the phloem. English-grown rhubarb, besides being smaller, bears much more of the bark, is roughly ridged or wrinkled, and is much softer and lighter in weight than that from China. On scraping down to the medullary rays, the exposed surface is found but little reticulated.

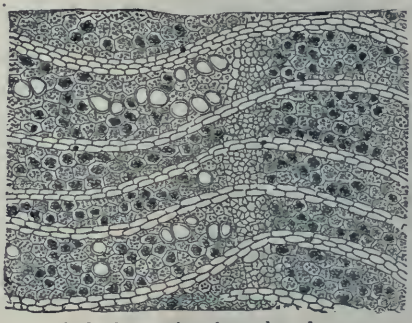
Powdered rhubarb ranges from a rather bright yellow brown to reddish brown. Under the microscope, its most prominent element is the numerous and large rosette-crystals of calcium oxalate, a majority of them being more than 50 mikrons in diameter. Both simple and compound starch-grains occur, the latter rarely of more than 3 granules, and they average about one-third as large as the crystal rosettes. Many smaller rosettes, of few slender crystals, of a deep reddish-brown color are also present. Fibrous elements should be scarce.

Adulteration.—Rhubarb in the entire condition is scarcely subject to adulteration, except by the easily detected Rhaponticum or garden rhubarb described below. Turmeric is often rubbed upon its surface to brighten its appearance. In the powdered condition it is highly subject to such adulteration, the commonest addition being Curcuma, easily detected by its starch-grains (see AMYLUM). Several pharmacopœias call

FIG. 340.

Chinese rhubarb: transverse section.

FIG. 341.



Rhubarb: section through and near cambium (× 40).

attention to the fact that a dark-blue color is produced by ferric chloride, a blood-red color by potassa. The Swiss states that if 50 Gm. of a 5 per cent. solution of sodium carbonate or borax be added to 0.5 Gm. of powdered rhubarb and 5 Cc. of the filtrate diluted to 200 Cc. the color should still be strongly reddish yellow. Also that if it be rubbed up with equal parts of ether and chloroform and spread upon filter-paper, the stain, after drying, should not become orange red upon the addition of a saturated solution of borax nor afterward blackish blue with ammonia (absence of Curcuma). The same substance is indicated when a few grains of the suspected powder added to a few drops of a colorless volatile oil imparts a strong yellow color to the oil about the edges of the particles, as seen under the microscope.

Constituents.—Procter ascertained that alcohol extracts from rhubarb from 30 to 36 per cent. of its weight; diluted alcohol with hydrochloric acid, 16 to 17 more; water with potassium hydroxide, about 26; the insoluble residue being from 21 to 27 per cent. The odorous principle, an oily substance extracted by chloroform, appears to be a derivative, since more of it forms after extraction. Active substances which have been extracted are the resinous matters and "cathartic acid," both of them apparently mixtures of two or more chemical substances. Cathartic acid has been removed by maceration and extraction with water, mixing the filtrate with 95 per cent. alcohol, again filtering, concentrating and treating with absolute alcohol, by which the substance is precipitated, to the extent usually of from 3 to 5 per cent. of the weight of the rhubarb. It is similarly obtained from Senna and some other purgative drugs. It has been found to possess, in doses of 2 to 5 grains, the general purgative properties of rhubarb.

It cannot be said that the activity of rhubarb has been located in any one chemical body. The best résumé of the characteristic constituents is that of Hesse (see *Pharm. Journ.*, 1895, 325), who has studied chiefly the crystalline constituents, which possess little or no activity. These he enumerates as follows: *chrysophanic acid*, or di-oxymethyl-anthraquinone, $C_{14}H_5(CH_3)(OH)_2O_2$, melting at 188° C. (370.4° F.); *emodin*, $C_{14}H_4(CH_3)(OH)_3O_2$; *rhein*, $C_{14}H_3(CH_3)(OH)_4O_2$. Tschirch obtained 1.5 per cent. of

emodin from rhubarb. These three substances are successive oxidation-products of an undetermined body which Hesse thinks is not the substance chrysophan so described by some. All were extracted by ether, together with the active resins, which were then removed by alcohol. From the crystalline residue, chrysophanic acid was obtained by repeated extraction with a dilute solution of potassium carbonate at 40° C. (104° F.), the remainder dissolved in alcohol or glacial acetic acid, and repeatedly recrystallized until the crystals melted at 178° C. (352.4° F.). After its removal it will re-form in rhubarb by exposure to air and water, especially under the influence of potassium hydroxide. It is improperly called an acid. The diluted potassium carbonate removes the emodin and rhein together. They are purified by acidulating with hydrochloric acid and extraction with ether. The emodin is then separated in boiling toluene. It dissolves in caustic alkalies and in potassium or sodium carbonate with a purple color. Lead acetate precipitates from the ammonia solution an amorphous, flocculent, purple body. From the residue, rhein is purified by recrystallization from hot glacial acetic acid. Rhein is practically insoluble in toluene, benzene, ether, cold glacial acetic acid, and is sparingly soluble in alcohol, the solution acid, and in hot glacial acetic acid. It melts to a black liquid at "considerably above 280° C." (336° F.). An amorphous, purple mass separates when the potassium carbonate solution is mixed with solid potassium carbonate. The resin of rhubarb is but little known, although it has been separated into phæoretin, aporetin, and erythroretin. The tannin of rhubarb is known as rheotannic acid. It is a glucoside, yielding *rheumic acid* ($C_{40}H_{32}O_8$). Gilson claims to have separated from it the following crystalline bodies: the glucoside *glucogallum* ($C_{15}H_{16}O_{10}$), a compound of glucose and gallic acid; *tetrarin* ($C_{32}H_{32}O_{12}$), consisting of glucose, gallic acid, and cinnamic acid; and the aldehyde *rhœosmin* ($C_{10}H_{12}O_2$), which melts at 795° C. (175° F.) and has the odor of rhubarb. The remainder, he says, is catechin. Rhubarb contains an unknown bitter principle, considerable starch, and an amount of calcium oxalate which has been reckoned as high as a third of the total powder, though this estimate is probably too high.

No comparison of the constituents of different species of Chinese rhubarb has been made.

According to Tschirch (*Arch. d. Pharm.*, 1902) rhubarb contains no resins whatever, and the purgative activity of the drug is due wholly to the presence of anthraglucosides and their derivatives already named above. Besides the anthraglucosides, tannoglucosides are also present, both evidently the result of primary formation in the plant. Both classes of glucosides are characterized by ready decomposition and conversion into secondary products, such conversion resulting even during the treatment of the drug with ordinary solvents. To what degree the primary anthra- and tannoglucosides have undergone hydrolysis in the drug itself, it is difficult to determine; while it is certain that the drug contains a considerable quantity of free oxymethylanthraquinones, it is possible that the formation of the secondary glucosides results during the extraction of the drug. The same author states that *rhein*, yielding only a diacetyl derivative, cannot be regarded as tetraoxymethylanthraquinone, as stated by Hesse, and has the composition $C_{15}H_8O_6$.

Pharmaceutical Preparations.—Extract of Rhubarb, Fluidextract of Rhubarb, Compound Powder of Rhubarb, Pills of Rhubarb, Compound Pills of Rhubarb, Aromatic Syrup of Rhubarb, Syrup of Rhubarb, Tincture of Rhubarb, U. S. P.

Action and Uses.—The action of rhubarb varies somewhat with the quantity administered. In small doses it is tonic and astringent, improves the appetite, digestion, and intestinal tone, but its continuous use will result in constipation. It produces catharsis if given in sufficient quantity for its purgative principle to be effective. The stools are soft and stained a yellowish brown. It was formerly supposed that this color was due entirely to the presence of the drug, but the investigations of Rutherford and Vignal seem to prove that rhubarb excites the flow of bile, to which the color is partly attributed. After the bowels have been evacuated the astringent principle exerts its influence and constipation results. The coloring-matters of rhubarb are absorbed from the alimentary canal and stain the perspiration, urine, and milk a yellowish tinge. The milk may, indeed, exhibit a bitter taste and purgative properties. If the urine be alkaline, it may be colored carmine. Rhubarb, as a tonic, is applicable to those cases of dyspepsia and duodenal catarrh accompanied by constipation. Its prolonged use, however, may increase the constipation instead of relieving it. As a laxative it is particularly efficient in the summer diarrhœas of infants and children, for, after it has unloaded the bowels of irritating, fermentative products, its astringent influence asserts itself and checks the

diarrhœa. The aromatic syrup is the preparation ordinarily preferred. If the stools are acid and irritating, alkalies, such as magnesium oxide or sodium bicarbonate, should be prescribed with the rhubarb. The constipating after-effect of rhubarb prohibits its use as a laxative in habitual costiveness. The preparations of rhubarb are unnecessarily numerous. The purgative dose of the drug in substance is from 20 to 40 grains (1.3–2.6 Gm.); the laxative or tonic dose is from 5 to 10 grains (0.30–0.60 Gm.). The aromatic syrup, in the dose of from 1 to 2 drachms (4–8 Cc.), is preferred for children. The soap in the pills increases the laxative effect of the rhubarb; 1 to 3 pills constitute a dose. The other preparations are discussed under their respective titles.

Related Drugs and Products.—The medicinally employed rhizomes and roots of other species of Rheum than those discussed above are classed under the general title *European Rhubarb* or *Rhaponticum*, though much of it, especially of that from the continent, is from other species than *R. rhaponticum* L., Holmes naming *R. undulatum* L. and *R. compactum* L. as the sole other sources of that seen in London commerce. Rhaponticum is usually less than half the size of rhubarb, more inclined to a conical form, harder, and lighter colored. The surface is wanting in the parti-colored reticulation, the medullary rays being straighter and the intervening spaces not exhibiting the grayish-white color of genuine rhubarb. The transverse section shows a strong dark cambium zone, and a less irregular radiation. Such stellate bundles as exist are not in a distinct and continuous circle, but more or less scattered. The taste is more bitter and astringent and the effect less gritty. The constituent *Rhapontin* ($C_{22}H_{24}O_9$) is distinct from any found in Rheum. Rhaponticum acts much like rhubarb, but is very inferior to it. Various pie-plant roots have been occasionally seen in commerce in the form of the unpeeled and untrimmed, wrinkled and blackish rhizome and roots. In India, the use of the rhizome and roots of *R. Emodi* Wall. is said to be steadily increasing.

Fig. 342.

Phaponticum: transverse section.

Rhubarb or Pie-plant stems have been found by Otto to contain 0.2 to 0.3 per cent. of oxalic acid, free or in soluble form. (For allied drugs and products, see Polygonaceæ.)

RHUS GLABRA, *U. S.*—Sumach.

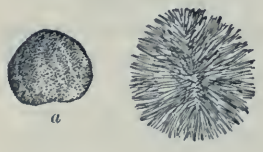
Smooth, Sleek, Scarlet, White, Pennsylvania or *Upland Sumach, Shoe-make, Vinegar-tree*, E.; *Sumach*, G.; *Sumac*, Fr.; *Zumaque*, Sp.

The dried fruit of *Rhus glabra* L. (*Toxicodendron glabra* Mill.—Fam. *Anacardiaceæ*).

This drug is not official in any other pharmacopœia.

Origin.—The plant, which grows in dry localities throughout most of North America, is a handsome, widely-spreading, soft-wooded shrub, often reaching a height of 10 or 12, occasionally 20 feet, and a trunk diameter of 6 or 8 inches or more. The bark is thin, brownish-gray and smooth, except for its small warts. The leaves are from 1 to nearly 3 feet in length and consist of from 11 to 31 leaflets, which are 2 to 4 inches long and a third to a half as broad, lanceolate, acuminate, rounded at the base, sharply serrate, thin, smooth, whitish underneath. The flowers are polygamous, mostly dicœcious, greenish-yellow, and come in large, dense, pyramidal, terminal panicles. The fruit is also in large, dense panicles, often a foot long and 6 inches broad, and of a bright crimson, becoming dark red or blackish as it clings upon the plant during the winter months. The wood, though soft and weak, takes a high satiny polish and is used in cabinet work. Both bark and leaves are largely used in tanning. The latter frequently bear small excrescences, which are especially rich in tannin.

Fig. 343.



a *b*

a, Rhus Glabra: b, R. hirta, (× 3).

Description.—A flattened-ovoid drupe about 4 Mm. ($\frac{1}{6}$ In.) long and equally broad or slightly broader, obtuse, truncate at the base, the epicarp deep crimson and glandular-tomentose, enclosing a yellowish, smooth stone containing a single seed; inodorous; taste acidulous and astringent.

Fruits having a long shaggy epicarp are not of this species.

This drug is subject to adulteration with the fruit of other species of *Rhus*. That of *R. hirta* (L.) Sudw. (*Datisca h.* L.; *R. typhina* L.), the

Staghorn, Velvet, Hairy or *Virginia sumac,* common in eastern and especially in northern North America, is readily distinguished by its shaggy coating of long, rather straight hairs. The plant is named in allusion to the velvety covering of the young stems. The fruit of *R. aromatica* Ait. (*R. Canadensis* Marsh.; *Toxicodendron crenatum* Mill.), the *Sweet* or *Fragrant sumac,* of the eastern and central United States, is smaller, less compressed and more nearly spherical. That of *R. Coriaria* L., the *European* or *Tanner's sumac,* is much rougher, or hispid.

Constituents.—Rhus glabra contains much malic acid in the epicarp and hairs, part of it combined with calcium. It contains also about 2 per cent. of tannic and some gallic acid. The seeds contain fixed oil.

Pharmaceutical Preparations.—Fluidextract of Rhus Glabra, U. S. P.

Action and Uses.—Rhus glabra is a very efficient gargle in acute and subacute inflammations of the throat. It is used either in infusion, made by adding 1 ounce (30 Gm.) of the berries to 1 pint (480 Cc.) of boiling water, or by adding the fluidextract to water and glycerine. The addition of potassium chlorate to saturation to either formula adds to the efficiency of the preparation.

Allied Drugs.—(See also Galla and Rhus Toxicodendron.) The bark and the leaves described above are employed medicinally, as well as for tanning, the bark containing 9 to 15 per cent. of tannin, the leaves 15 to 25 per cent. All the other species named above have a similar composition and are more or less used similarly.

Rhus aromatica.—The root-bark of this species is largely used among the eclectics. It is about 2 Mm. ($\frac{1}{12}$ In.) thick, covered with a fissured and warty brown cork (underneath which the bark is orange-red), and is whitish or pale-brownish in color. It is brittle, breaks with a short, granular fracture, yields an ochre-colored powder, and has a slight pleasant odor and an astringent, aromatic and bitterish taste. The bark contains scattered oil-cells, and has a somewhat checkered appearance from the tangential arrangement of the bast-layer and the radiating delicate medullary rays. In addition to the tannin, as in other species, this contains an alcohol-soluble balsamic oleoresin. Its fruits contain about 10 per cent. of citric acid (Claassen).

The leaves and bark of many other of the 120 recognized species of Rhus are used for their tannin.

RHUS TOXICODENDRON.—Rhus Toxicodendron.

Folia toxicodendri.—Mercury or *Black mercury, Poison oak, Poison, Climbing* or *Three-leaved ivy, Climbing* or *Trailing sumac, Piery, Poison-vine,* E.; *Giftsumach, Giftbaum,* G.; *Sumach vénéneux,* Fr.; *Toxicodendro, Zumaque venenoso,* Sp.; *Sumagre venenosa, S. pubescente,* Port.

The fresh leaflets of *Rhus radicans* L. (*R. Toxicodendron* L. *Toxicodendron vulgare* Mill.—Fam. *Anacardiaceæ*).

Poison ivy is official only in the Spanish and Portuguese pharmacopœias.

Origin.—From a slender shrub, abundant throughout the greater part of North America and somewhat naturalized in Europe. It either trails over the ground, often for several yards, or climbs fences and trees by means of a hair-like growth of false roots which serve no other purpose than to give support. Occasionally, the stem thickens so as to stand erect without other support. This is common with the southern form, to which the name *R. Toxicodendron* (*T. pubescens* Mill.) was applied by Linné. The leaves are long-petioled and have 3 or occasionally 5 leaflets, described below, the lateral sessile or nearly so, the terminal long-stalked. The small greenish flowers are produced in June, in loose drooping panicles, about 2 to 10 Cm. (1 to 4 In.) long, which become somewhat larger in fruit. The fruit is an elongated-globose, gray-green drupe, about 4 Mm. ($\frac{1}{6}$ In.) in diameter. This plant is sometimes mistaken for the Virginia Creeper (see Vitaceæ), which is quite harmless. Poison Ivy is probably the most important vegetable cutaneous poison in existence (see *Action and Uses*). The popular impression that poisoning can result without direct contact with the plant is fully verified. This may occur to one who whips the leaves from a little distance, or even by standing in a strong wind blowing from the plant, and has been explained upon the theory that pollen-grains, or the minute hairs loosened from the leaf, are deposited upon the skin. Both these parts have been experimentally proved capable of producing poisoning. Smoke from the burning plant is also regarded as poisonous, but no proof has ever been recorded in such a case that the poisoned individual had not handled the material. Cases are

recorded of reputed poisonings by being present in a room where the tincture was being bottled. The milky juice turns black upon exposure and can be used as an indelible ink, although it is soluble in ether.

Description.—The leaflets vary from 3 to 20 Cm. (1 to 8 In.) long and more than half to nearly as broad, and are equilaterally (the terminal) or inequilaterally (the lateral) ovate, abruptly short-acuminate, often cuneate (the terminal) or rounded (the lateral) at the base. The margin varies from entire to coarsely and irregularly toothed or crenate, occasionally lobed. The surface varies from smooth and slightly satiny-lustrous to more or less pubescent, especially underneath. The texture is very thin and flaccid, the venation pinnate and slender. They are inodorous, slightly astringent, saline and acrid to the taste.

FIG. 344.

Rhus toxicodendron: leaf (½ Nat.).

Constituents.—Tannin, wax, gum, starch, and resin have been found in this drug, together with the peculiar alcohol-soluble fixed oil or fat *toxicodendrol*, closely allied to *cardol* (see ANACARDIUM). The active principle was regarded by Khittel as a volatile alkaloid, but no one else has been able to confirm the statement. Maisch regarded it as a volatile acid (*toxicodendric acid*), but Pfaff and Orr declare this, when purified, to be non-toxic and to agree with the characters of acetic acid. They find the toxicodendrol to be intensely poisonous, very minute portions producing sensible effects. It has been found present in the leaves to the extent of 3 per cent., and is easily soluble in alcohol, ether, benzene, and chloroform. It produces an insoluble compound with lead. The chemical characters of this fat require further study. It appears reasonable to suppose that, as in the case of Croton oil and similar fats, the active principle is the freed fat-acid, and this has not been studied. It may be, as stated by Maisch, volatile.

Action and Uses.—On man the volatile acid from the living plant of rhus toxicodendron is a powerful local irritant, some individuals being so susceptible to its influence that air impregnated with exhalations from the plant is sufficient to produce the characteristic eruption in them. Herbivorous animals devour its leaves with impunity, but its juice is fatal to dogs. The cutaneous inflammation produced by poison ivy begins to appear between a few hours to several days after exposure, and is characterized by intense itching, redness, and swelling, followed by heat, pain, and vesication. Many remedies have been suggested for the treatment of the eruption.

None of them are curative, but are designed to relieve the itching and irritation. The fresh juice of Impatiens is said to be beneficial when locally applied. Probably the most effective, certainly the most frequently employed, are lead-water and laudanum, or fluidextract of grindelia diluted with alcohol and water. Internally in large doses it gives rise to a burning sensation in the throat and œsophagus, thirst, nausea, faintness, vertigo, delirium, and convulsions. The pupils are dilated and the pulse, at first slow and full, later becomes rapid, irregular, and feeble. In some cases of poisoning by the plant, taken internally, vesicular eruptions have appeared on the skin. Recommended formerly as an internal remedy in incontinence of urine dependent upon atony of the bladder, acute articular and chronic muscular rheumatism, paralysis, and other affections, its use has not produced good results and has been abandoned.

Allied Plants.—Not only do other species of this section of the genus, distinguished by their smooth fruits containing a grooved stone, share the poisonous properties of *Rhus radicans*, but several related genera do likewise. The following are those best known:

Rhus Vernix L. (*R. venenata* DC.; *Toxicodendron pinnatum* Mill.), the *Poison* or *Swamp sumac* or *Dogwood*, *Poison-elder*, *-ash* or *-tree*, is abundant in eastern and central North America. It somewhat resembles *R. glabra*, but is readily distinguished by its reddish petioles and midribs, green lower leaf-surfaces, very loose, open, slender panicles, drooping in fruit, and its smooth fruit. It always grows in wet ground.

FIG. 345.

Rhus vernix L.

R. diversiloba T. et G. (*R. lobata* Hook.) is the *Californian*, *Pacific*, or *Western poison oak*. It quite closely resembles *R. radicans* in habit and appearance.

R. microcarpa (Mx.) Steud. (*R. Toxicodendron microcarpa* Mx.), of Michigan, with somewhat of the habit of Poison Ivy, *R. Michauxii* Sargent (*R. pumila* Mx.), of the eastern United States, and *R. Ryderbergii* Small, of the western United States, are little-known species.

R. vernicifera DC. (*R. Vernix* Thunb.) is the *Japanese lacquer tree* or *varnish-tree*, the varnish or lacquer being the very poisonous milk-juice which exudes from incisions made for the purpose, and suitably prepared. Violent poisoning is common among the workmen. This species closely resembles *R. Vernix* L.

Metopium Linnœa Engl. (*Rhus Metopium* L.; *R. oxymetopium* Griseb.) is the *Coral sumac, Mountain manchineel, Bum-wood,* or *Poison-wood* of Florida and tropical America. It is one of the sources of the Hog-gum or Doctor's gum (see ACACIA). It is the largest of this poisonous group, reaching to 30 feet in height. Its leaves bear 5 long-stalked, ovate, entire, smooth, thickish leaflets and the fruit is red. *M. venosum* (Griseb.) Engl., of Cuba, is very similar.

Comocladia, P. Browne (*Dodonœa* Plum.), contains some 9 species of West Indian and Central American shrubs and trees, mostly with spiny-toothed, coriaceous leaflets. Most, if not all of them, are intensely poisonous, and several are known by the vernacular name *Guao.* In 1900 a number of men forming a landing-party from the U. S. Ship "Richmond" were severely poisoned by *C. platyphylla* A. Rich. The spread of the poison was readily checked by applying fluidextract *Grindelia robusta,* and still better by collodion.

Lithræa caustica Miers (*Rhus c.* Hook), the *Litli,* occupies a similar position as an agent of poisoning in Chile, which *Rhus radicans,* etc., do in the United States, and *Comocladia* in the West Indies. *Pseudosmodingium perniciosum* (H. B. K.) Engl. (*Rhus p.* H. B. K.) does the same in Mexico, where it is known as *Goarchitin* or *Stinking wood.* Its milk-juice has been used as a purgative and diuretic. *Melanorrhœa laccifera* Pierre, of Eastern Asia, is to be compared with *Rhus vernicifera,* yielding like it a juice which is used as a black dye or varnish, and being similarly poisonous. *Holigarnea ferruginea* March., of the East Indies, contains a poisonous cardol-like substance. *Gluta Renghas* L., of southeastern Asia, has a similar poisonous juice. The oily juice of the pericarp of *Anacardium* has been known to produce cutaneous poisoning, as has that from several species of *Semecarpus,* and it is quite likely that very many other plants of this family, not now suspected, will be found poisonous in greater or less degree.

ROSACEÆ.—The Rose Family.

This family, if we include in it as subfamilies the *Drupaceæ* or Plum family and *Pomaceæ* or Pear family, comprises neary 100 genera and 1500 species. From a medicinal point of view it is rather uninteresting, its drugs being mostly astringents, though we have elsewhere discussed the important articles RUBUS, ROSA, OLEUM ROSÆ, QUILLAJA, CUSSO, GILLENIA, PRUNUS VIRGINIANA, and the AMYGDALÆ, besides a number of astringents in connection with GERANIUM and RUBUS. Otherwise than medicinally the family is of great importance. It is first among fruit-producing families, supplying the apple, pear, quince, medlar, peach, plum, apricot, cherry, nectarine, strawberry, raspberry, blackberry, service-berry, etc. In the ornamental species which it contributes to cultivation it is also among the first families. The principal minor drugs of the family are the following:

Spiræa or *Hardhack* (*Purple* or *Spice hardhack, Pink meadow-sweet* or *-queen*) is the root, bark, leaves, or flowers of *Spiræa tomentosa* L., a shrub about a meter high, of peculiar appearance, growing throughout eastern and central North America, in poor soil, especially where slightly boggy or moist. The stems are strict, little erect-branched, pubescent, densely clothed with the more or less erect leaves, which are short-petioled, 3 to 5 Cm. (1–2 In.) long, and a little more than half as wide, ovate, irregularly and rather coarsely serrate, smooth above, rusty or white woolly underneath. The flowers are borne in narrow, steeple-shaped terminal panicles, of a beautiful rosy pink. They are usually only about 4 Mm. ($\frac{1}{6}$ In.) broad, and have a small 4- or 5-lobed calyx bearing an equal number of petals and numerous conspicuous stamens. The pistils are several, distinct, and become follicles in fruit. The drug has a little bitterness with its astringency, and the flowers are somewhat fragrant. The drug is used wholly for the contained tannin, the amount of which has not been determined.

S. salicifolia L., the *Common* or *Willow-leaved meadow-sweat, hardhack* or *Queen-of-the-meadow, Mock-willow* or *Bridewort,* is abundant in the same region and also grows through northern Europe and Asia. It is more inclined to grow in dryer ground, and has a more spreading habit, its leaves smooth, its flowers usually white (sometimes pink), in broader, shorter, and looser panicles. It is used similarly, as is the European *S. Filipendula* L. (*Filipendula vulgaris* Moench), called *Dropwort* or *Droopwort.* The genus comprises some 40 species and about a dozen of these are recorded as being similarly used.

Ulmaria, Meadow-, Honey-, Maid- or *Bride-sweet* (*Ulmarispiräe, Medesüss, Krampf, Geissbart,* G.; *Ulmeira, Siene des piês,* Fr.), is the herbage of *Ulmaria Ulmaria* (L.) Barnh. (*Spiræa u.*—L.; *U. palustris* Moench; *Filipendula u.*—Maxim.), of Europe. It is one of 9 species, long confused with *Spiræa,* and containing, in addition to tannin, considerable volatile oil, consisting chiefly of salicylous acid. The plant is a branching perennial herb, with interruptedly pinnate leaves, the leaflets lance-oblong to ovate, and serrate, the small white flowers in long-peduncled corymbs. *Aruncus Aruncus* (L.) Karst. (*Spiræa A.*—L.), the *Goat's-beard* (*Bock-bart,* G.; *Barbe chèvre,* Fr.), is a somewhat similar herb, but with the white flowers in ample panicles. It is native of northern Europe and North America and a related

species is a favorite flower of cultivation. Its constituents and properties are similar to those of the last.

Sorbus or *Mountain-ash* (*Wild ash, Whistle-wood, Witch-wood, Wicker* or *Rowan-tree*, E.; *Eberesche, Vogelbeere*, G.; *Sorbar*, Fr.) is *Sorbus Aucuparia* L. (*Mespilus A.*—Scop.; *Pyrus A.*—Gærtn.), a small tree of Europe and adjacent Asia, and cultivated for ornament. It has large pinnate leaves, whence its resemblance to the ash, and terminal corymbs of white flowers, followed by light-red, ovoid, juicy fruits, tipped by the calyx-lobes and containing about three 2-seeded cells. These fruits are the portion used, in either the fresh or the dried state. They contain tartaric acid before, citric and malic acids after ripening; two sugars, sorbin and sorbit, the latter often fermentative; parasorbic acid ($C_6H_8O_2$), which is aromatic and is converted into isomeric sorbic acid by heating under pressure with potassa; bitter, acrid and coloring-matters.

The bark is astringent, and yields amygdalin. The American species *S. Americana* Marsh. (*Pyrus A.*—DC.; *S. microcarpa* Pursh.), which bears many local names, is very similar. A large number of species of this, and of the related genus *Pirus*, are employed. The related genus, *Crotoneaster nummularea*, F. et M., of Persia and India, yields an *Oriental manna*, believed to be the same as *sorbit*.

Agrimonia or *Agrimony* (*Herba Agrimoniæ.—Odermening, Leberklette*, G.; *Aigremoine, Eupatoire des Grecs*, Fr.) is the dried plant *Agrimonia Eupatoria* L., a perennial herb of Europe, about 2 feet high, growing along roadsides, about houses, and in the borders of morasses and thickets. The root is fibrous, several-headed, and brown; the stem almost simple; the leaves about 13 Cm. (5 In.) long below, pinnate, with 4 to 8 pairs of elliptic-oblong, coarsely toothed leaflets, intermixed with several pairs of minute ones; the stipules semi-cordate, clasping, and coarsely serrate. The yellow flowers are rather small, in slender spicate racemes, and have a persistent top-shaped calyx, which is covered with hooked bristles. The plant is collected while flowering from June to September and deprived of the coarse stems. It has a very faint aromatic odor and a bitterish, mildly astringent taste, which is stronger in the root. Bowman reported it as containing 4.75 per cent. of tannin, besides which there is a bitter volatile oil. The genus contains about 20 species, and all are apparently closely similar in constituents and properties.

Fig. 346.

Agrimony (½ Nat.).

Closely related to Agrimonia are the genera *Poterium, Acœna*, and *Alchemilla;* a dozen or more species of these have been used as astringents, almost precisely like Agrimonia.

Geum or *Water-avens* (*Radix caryophyllatæ aquaticæ, R. benedictæ sylvestris.—Purple* or *Drooping avens, Throat-root, Chocolate-root*, or *Indian chocolate*, E.; *Sumpfnelkenwurzel, Wasser-Benedikten-Wurzel*, G.; *Racine de bénoite aquatique* or *des ruisseaux*, Fr.) is the dried rhizome and roots of *Geum rivale* L., a perennial herb of wet places almost throughout the north-temperate zone. It has a stem 30 to 60 Cm. (1–2 Ft.) high, with lyrate or interruptedly pinnate root-leaves and trifoliolate or 3-lobed stem-leaves, the leaflets or lobes being obovate or cuneate-oblong; the bell-shaped calyx is purplish brown; the 5 petals are clawed, purplish yellow, and veined. The rhizome is nearly horizontal, 5 to 7 Cm. (2–3 In.) long, about 6 Mm. (¼ In.) thick, somewhat branched, tuberculate above from the bases of the stems, and there densely beset with red-brown hairy leaf-sheaths. It is externally blackish brown, breaks with a rather short and waxy fracture, and has a thin purplish-brown bark, brown-gray pith, and small distant light-colored wood-wedges. It has a very faint, somewhat clove-like odor and a bitterish-astringent taste.

Fig. 347.

Purple avens (¾ Nat.).

Geum urbanum L. is commonly known as *Avens* or *Yellow avens*, also *City avens*, *Clove-root*, *Bennett* (*Radix caryophyllatæ—Nelkenwurz*, G.; *Benoite*, Fr.). It is a yellow-flowered species, of Europe, somewhat naturalized in the United States. Its rhizome is oblique or perpendicular, 25 to 50 Mm. (1–2 In.) in length, abrupt below, or passing into the main or tap-root; it is hard, dark-brown, tuberculate, and beset with dark-brown membranous scales; the numerous thin fibers are pale-brown, and 7 to 10 Cm. (3–4 In.) long; the wood is in 5 or 6 broad and rounded wedges and encloses a large purplish pith. It has a distinct clove-like odor and a bitter astringent taste.

Two white-flowered species of eastern North America are *G. Virginianum* L., the *Rough white avens*, or *Red-root*, and *G. Canadense* Jacq. (*G. album* Gmel.), the *American white avens*.

G. urbanum has been found to contain tannin, volatile oil, and a bitter principle, resin, gum, fat, and sugar.

Several other of the 40 species of the genus are similarly used.

The unripe fruits of various species of *Crataegus* or *Hawthorn*, especially *C. Oxyacantha* L., the English Hawthorn, are used for their astringent properties.

Cercocarpus ledifolius Nutt., or *Mountain mahogany*, of the great western desert plains of the United States, is a much-used astringent among frontiersmen. *Cowania Mexicana* Don, a closely related plant or the same region, besides being astringent, bears upon its leaves and twigs an abundance of a strongly odorous oleoresin, and is extremely bitter. Its constituents and properties are well worthy of investigation.

ROSA GALLICA, *U. S.*—Red Rose.

Rosæ gallicæ petala, Br.; *Flores rosarum rubrarum.—Red-rose petals*, E.; *Essigrose, Sammtrose, Zuckerrose*, G.; *Rose rouge, Rose de Provins*, Fr. Cod.; *Flore. do Rosa Rossa*, It.; *Rosa roja, R. rubra*, Sp.; *Rosas rubras, Rosa Franceza Dobrada*, Port.

The dried petals of *Rosa gallica* L. (Fam. *Rosaceæ*), collected before expanding.

Red-rose petals are official in nearly all pharmacopœias.

Origin.—This species, which bears bristly prickles and a few curved spines, and the leaflets of which are slightly cordate at the base, is a native of southern Europe and the Levant, and is everywhere cultivated for ornament in many varieties. For the production of the commercial petals it is chiefly cultivated in southern France, though the industry is carried on to some extent in nearly all parts of central and southern Europe. With a sharp knife, the unopened corolla-bud is circumcised near the base, so as to leave the stamens behind upon the calyx. The resulting cones should be quickly dried and kept entire as nearly as possible.

FIG. 348.

Rosa gallica.

Description.—Mostly in small cones consisting of the naturally imbricated petals, deep purplish-red, and with a velvety looking surface; the unfolded petals roundish, retuse at the summit, narrowed at the base into a short, broad, yellow claw, the most of which has been trimmed off; of a fine rose-like odor, and a bitterish, slightly acrid and astringent taste.

Constituents.—The important constituent of Red Rose is the red coloring-matter. It was isolated by H. Lenier (1877) by exhausting the petals with ether, and afterward with alcohol; the tincture was precipitated with lead acetate, and this precipitate decomposed by an insufficient quantity of sulphuric acid in the presence of alcohol. The coloring-matter becomes deep-red, with a bright-green fluorescence, by alkalies; it decomposes carbonates, yields with alkalies crystallizable compounds, and is precipitated by salts of alkaline earths and metals, the lead salt having the composition $Pb_2C_{21}H_{29}O_{30}$. The astringency is due to a little gallic acid and the glucoside *quercitrin*, together with a little quercetin, a decomposition-product of the former. The presence of tannic acid is in question. The odor is due to a very small amount of volatile oil, not identical with the official OLEUM ROSÆ. A considerable amount of sugar, gum, fat, etc., are also present.

Pharmaceutical Preparations.—FLUIDEXTRACT OF ROSE, HONEY OF ROSE, SYRUP OF ROSE, U. S. P.

Action and Uses.—Formerly employed for their mild astringency, red rose leaves are to-day used almost solely to impart their pleasant odor to pharmaceutical preparations.

Allied Products.—ROSA CENTIFOLIA or PALE ROSE (*Rosæ centifoliæ petala*, Br.; *Flores rosæ*, P. G.; *Flores rosarum incarnatarum.—Cabbage rose-petals, Hundred-leaved Rose*, E.;

Centifolienrose, Rosenblätter, G.; *Rose à cent feuilles, Rose pâle*, Fr. Cod.; *Flores di Rosa Pallida*, It.; *Rosa pallida, Rosa de Castilla*, Sp.; *Rosas Pallidas*, Port.) is the petals of *Rosa centifolia* L. It is official in nearly all pharmacopœias. This well-known shrub, which is by some botanists regarded as a cultivated variety of the red rose, is probably indigenous to Western Asia, and is cultivated in innumerable varieties in all countries. Its branches are covered with numerous nearly straight spines; the petioles and peduncles are nearly unarmed, but more or less clothed with glandular bristles, and the leaves have 5, or sometimes 7, ovate or elliptic-oval serrate, glandular, and, beneath, soft-hairy leaflets. The flowers are collected and deprived of the calyx and ovaries, the petals alone being employed. The petals are roundish-obovate, retuse at the apex or almost obcordate, of a pink color, a delicious rose odor, and of a sweetish, somewhat bitter, and slightly astringent taste. In drying, they become brownish and less fragrant. The constituents of White Rose are closely similar to those of the Red. There is very little coloring-matter, apparently identical with that of Red Rose. A little tannin is present.

Rosa Caninæ Fructus, Rose Fruit or *Rose hips* (*Cynosbata, Fructus cynosbata.—Dog-rose fruit*, R.; *Gratte-cul*, Fr.; *Cynorrhodon*, Fr. Cod.; *Hagebutte*, G.; *Cinosbato, Escaraninjo, Uva de gato*, Sp.), long official in the B. P., but now discarded, is the ripe fruit of *Rosa canina* L., and of other species of Rosa. This, the Dog-rose of Europe, is very similar to the Sweetbriar rose, and is slightly naturalized in eastern North America. The fruits are about 25 Mm. (1 In.) in length, ovate, contracted above, of a bright-red color, shining, internally stiff-haired, and enclose a number of ovate, hairy, brownish, bony akenes. Hips are at first tough and crowned with the 5-cleft deciduous calyx-lobes; later in autumn they are naked above, softer, and more fleshy. They are inodorous and have a sweet acidulous and somewhat astringent taste. For medicinal use, the hard akenes are removed and the fleshy calyx-tube alone is employed. Scheele noticed malic and citric acids in the pulp. Biltz (1824) obtained 7.78 per cent. of malic and 2.95 of citric acid; also 30.6 of sugar, 25 of gum, and small quantities of tannin, resin, wax, malates, citrates, and other salts. Hips are described as slightly refrigerant and astringent, but they are used in medicine only to prepare the confection of hips.

ROSMARINUS.—Rosemary.

Folia rosmarini, F. roris marini, F. anthos.—Old man, E.; *Rosmarin, Meerthau*, G.; *Romarin*, Fr. Cod.; *Romero*, Sp.

The dried leaves of *Rosmarinus officinalis* L. (Fam. *Labiatæ*).

This pretty, much and slenderly branched evergreen shrub, about a meter high, and bearing small pale-blue axillary flowers, is a native of the Mediterranean basin. It is cultivated for ornament and as a domestic herb, and to some extent for the distillation of its oil, but the drug, as well as the oil, is chiefly derived from wild sources.

Description.—About 2.6 Cm. (1 In.) long, linear by the strong revolution of the margins, oblong when flattened, sessile, obtuse at both ends, entire, of leathery texture, dark-green above, densely woolly and glandular-dotted underneath; odor peculiarly aromatic, somewhat camphoraceous; taste pungently aromatic.

Constituents.—The drug contains from 1.5 to 2 per cent. of volatile oil (see Oleum Rosmarini), together with considerable resin, tannin, and a small amount of an unstudied bitter principle.

Action and Uses.—The uses of rosemary are the same as those of the oil (see Oleum Rosmarini).

RUBIACEÆ.—The Madder Family.

Genera about 350, species nearly 5000, most abundant in the tropics, throughout the world, and decreasing as the climate becomes cooler. The family yields many edible fruits, but scarcely any of them are very good, and it cannot be considered of any importance as a food-producer. Its timbers have been little used, though many of them have most valuable properties, and will, without doubt, become highly prized for special uses. Many of its species are highly ornamental, in both foliage and flowers, and have become favorites for decorative purposes. The principal economic importance of the Rubiaceæ has been as a producer of dyestuffs, and even more so as a producer of drugs. The number of species yielding drugs to commerce is remarkably small, in view of the great number of domestic remedies, of undoubted activity, that the family produces. The most interesting characteristic of the family is the great number and variety of its alkaloids, in which it is scarcely excelled by any other. The physiological properties of the Rubiaceous drugs are very

diverse in character, though bitter tonics and febrifuges predominate. The astringent drug GAMBIR has been separately discussed. Although this property is shared by many species, yet astringency can scarcely be regarded as characteristic of this family. Many of the fruits, in an unripe condition, are so used, much like persimmon. Such is the case with those of several species of *Genipa*, especially *G. Americana* L., though edible when ripe. It contains tannin, the glucoside genipin and mannit, in which last the leaves are said to be very rich. Mannit is also abundant in the leaves and bark of *Basanacantha spinosa ferox*. The constituents and properties of the ripe and unripe fruits of *Gardenia Brasiliensis* Spr. are practically the same as those of Genipa. That of *G. jasminoides* Ell., the Japanese *Shang-shih-see*, Chinese *Shan-chi-tsze*, has many medicinal uses in the Orient. Many other species of Gardenia are employed medicinally. *G. radicans* Thunb. is the Chinese *Hwang-chi-tsze*. *G. suaveolens* Vell. is the Brazilian *Lasanjus de mate*. *G. gummiifera* L. and *G. lucida* Roxb. yield the East Indian Elemi-like substance *Decamala resin*. The fruits, as well as the barks, of various species of *Randia* are used as astringents, though the fruit-pulp of *R. Mussænda* DC. is a laxative. The fruit of *R. dumetorum* L. (*R. spinosum* Bl.), of the East Indies, is used medicinally and as a fish-poison, and bears a large number of local names. Its root is a nauseant and antispasmodic.

The properties of *Caffea*, of this family, are also separately considered. The seed of *Diplospora sphærocarpa* Hook. is said to be used in India as a coffee-substitute.

Under IPECACUANHA, many species have been cited as possessing properties similar to those of that drug, but the number, pertaining to this family alone, might have been greatly extended.

Of Cinchona-substitutes the same is true. Dozens of barks of this family are employed domestically, and many of them professionally, in tropical countries, for properties similar to those of Cinchona.

Some of the more important of the minor drugs of this family are the following:

Mitchella, Squaw-vine or *-plum, Partridge-, Chicken-, Cow-, Deer-, Box-, Fox-, Snake-*, or *Two-eyed berry, Running-* or *Ground-box* or *Winter clover*, is the dried stems and leaves of *Mitchella repens* L., a slender creeping evergreen of eastern and central North America. The stems reach 1 foot or 2 feet in length; leaves opposite, short-petioled, about 8 to 12 Mm. ($\frac{1}{3}$–$\frac{1}{2}$ In.) long, roundish-ovate, entire, thickish, deep-green or bearing whitish margins. The flowers are in pairs, often dicœcious, have a white or pale-purplish funnel-shaped corolla, and 4 exserted or included stamens, and produce a rather dry berry-like scarlet-red fruit, which is composed of 2 united ovaries and contains 4 bony nutlets. The flowers are fragrant; the leaves are inodorous, somewhat astringent, and bitter. Brenneiser (1887), besides the usual constituents of plants, found a saponin-like body, precipitable by baryta, and frothing in aqueous solution, and also a principle yielding precipitates with tannin and picric acid, but being neither alkaloid nor glucoside.

Various species of *Galium* have been employed in medicine, chiefly as diuretics, and for various skin diseases. That commonly employed is *G. verum* L. (*G. luteum* L.; *G. floridum* Salisb.), the *Tallow* or *Lady's bed-straw* or *Cleavers, Curdwort* or *Cheese rennet plant* (*Megerkraut, Labkraut, Liebfrauenstroh*, G.; *Caille lait jaune*, Fr.; *Cuajaleche*, Sp.), a slender, much-branched perennial herb of Europe and temperate Asia and naturalized in North America. The root is light red, the stem weak and smooth, the leaves in whorls of 8, narrowly linear, rough, the panicled flowers small, yellow, fragrant, the fruit small, strongly 2-lobed, smooth. The herb is astringent, acidulous, and bitter. Little is known of its constituents, except that it contains several common vegetable acids and some tannin, but it probably also contains one or more alkaloids. It has been used to curdle milk. *G. Aparine* L., known generally by the same names, also *Catch-, Cling-, Snatch-*, or *Grip-weed* or *-grass*, and by very many other domestic names, is a very slender European species, abundant in the United States, which has also been much used. The stem is long, reclining, sharply quadrangular, and retrorsely hispid on the angles. The leaves are commonly 6-whorled, lance-linear, mucronate, and retrorsely hispid, the white flowers scattered. *G. triflorum* Mx., the *Sweet-scented bed-straw*, exhales the odor of cumarin produced in drying. The same is true of *Asperula odorata* L., the *Sweet woodruff* or *Sweet hay-plant* (*Waldmeister, Herzfreude, Sternleberkraut*, G.; *Aspérule*, Fr.), which yields the European *Herba asperulæ, cordialis*, or *matrisilvæ*. *Galium tinctorium* L. yields a red coloring-matter and is often called *Wild madder* or *Dyers'-cleavers* or *bed-straw*. *G. circæzans* Mx. and *G. lanceolatum* Torr., of the eastern United States, have a liquorice-like sweetness and are sometimes called *Wild liquorice*. Some 25 species of *Galium* and *Asperula*, very closely related, have been employed.

Cephalanthus, Buttonbush, Buttonwood, Swamp dogwood, Crane willow, Wild liquorice, Honeyball, or *Pinball*, is the bark, more especially of the root, of *Cephalanthus occidentalis* L. The shrub grows in swamps almost throughout the United States, and extends into southern Canada. It is a large, widely spreading shrub, with rich glossy foliage. The leaves (sometimes in two's) and flower-heads are here illustrated. The commercial bark occurs in small fragments, about 1 or 2 Mm. ($\frac{1}{25}$ or $\frac{1}{12}$ In.) thick. That of the stem is grayish brown, finely striate and somewhat glossy if young, or dull ashy gray, fissured and scaly if older. That

of the root is in shorter and more irregular fragments and of a brown and somewhat rusty color. The inner surface is whitish when fresh, becoming light rusty brown, and very finely striate. The fracture is rather tough-fibrous. It is nearly odorless, bitter and slightly astringent. The bark contains cephalanthin, cephalin, starch, sugar, gum, fat, several resins, tannin, and a saponin-like principle. *Cephalanthin* ($C_{22}H_{34}O_6$) is an amorphous, very bitter glucoside, soluble in alcohol and acetic ether, and with difficulty in ether, chloroform, and water. The aqueous solution foams on shaking. Boiled with acids, it yields crystalline *cephalanthein* ($C_{16}H_{28}O_3$) and sugar. *Cephalin* is a yellowish-white, crystalline, tasteless glucoside soluble in alcohol, ether, and chloroform, and with difficulty in water. It is strongly fluorescent in solution. With acids it yields sugar and crystalline *cephaletin*, which fluoresces in alkaline solution.

FIG. 349.

Cephalanthus twig (½ Nat.), with flower (× 3).

Cahinca Root (*Radix caincæ* or *cainanæ.*—*Caincawurzul*, G.; *Cainça*, Fr.) is the root of the tropical American *Chiococca brachiata* R. et P. (*C. densifolia* Mart.; *C. anguifuga* Mart.) and of *C. alba* (L.) Rusby (*Lonicera a.*—L.; *C. racemosa* Jacq.). There is considerable doubt as to the applications of the names to the respective drugs, owing doubtless to the great variability of the species. They are also called *Snowberry*, *Brazilian snake-root*, *Rais preta do Brazil*, etc. They apparently have important tonic properties. The woody root occurs in pieces 7 to 15 Cm. (3–6 In.) long, about 2 to 6 Mm. ($\frac{1}{12}$–$\frac{1}{4}$ In.) thick, more or less bent, externally blackish- or grayish-brown, finely wrinkled longitudinally, with narrow transverse corky ridges and fissures, with a thin brown bark of a resinous lustre internally, and with a whitish wood. It is usually mixed with portions of the lower stem, which are 12 to 25 Mm. ($\frac{1}{2}$–1 In.) thick, and have deep longitudinal furrows, with intervening rounded, often very prominent, ridges produced by separated wood-bundles, which have not been developed into separate branches; the porous wood encloses a thin pith and is radiate. The bark has a nauseous, bitter and acrid taste. It contains green fatty matter, of a nauseous odor, yellow coloring-matter, a colored viscid substance, tannin (caffeotannic acid?), and *cahincin* or *cahincic acid* ($C_{40}H_{64}O_{18}$). This latter forms white, odorless, very bitter, and slightly astringent silky needles, soluble in 600 parts of water and readily in alcohol. Treated with dilute hydrochloric acid it yields at first glucose and chiococcaic acid ($C_{28}H_{42}O_7$), and by prolonged boiling, *caïncetin* ($C_{22}H_{34}O_5$), the alcoholic solution of which gelatinizes on the addition of water. Cahincic acid exists in the root partly free and partly as a calcium salt.

Rubia, or *Madder* (*Krapp*, *Färberröthe*, G.; *Garance*, Fr.; *Granza*, Sp.), is the root of *Rubia tinctoria* L., a perennial herb, native of the Levant and largely cultivated in various countries for its value as a dye, its medicinal use having nearly ceased. The roots are numerous, elongated, cylindrical, about as thick as a quill, light blood red, easily separable into a gray-red corky layer, a thin dark brown-red inner bark, and a spongy red wood, with irregular medullary rays. It is of a feeble color, and a sweetish, bitterish, somewhat acrid and astringent taste. Madder is usually found in the shops in the form of a coarse powder. The fresh root contains a yellow coloring-matter, while the commercial article contains the decomposition-products, many being glucosides, yielding *alizarin*. *Rubian* is amorphous, dark yellow, bitter. *Rubihydran* and *rubidehydran* are gum-like (Schunck, 1847–56). Rochleder's *ruberythrinic acid*, $C_{20}H_{22}O_{11}$ (1855, etc.), crystallizes in silky yellow prisms. The most important constituent is *alizarin*, $C_{14}H_8O_4$, which crystallizes in orange-red sublimable needles, is soluble in boiling water, alcohol, and ether, and yields purple or red-colored compounds with bases. Other compounds obtained from madder are *rubitannic acid*, *rubichloric acid*, *purpurin*, *rubiretin*, etc. The artificial production of alizarin was discovered by Graebe and Liebermann,

and it is now manufactured from *anthracene*, $C_{14}H_{10}$, a crystalline constituent of coal-tar, which is oxidized to *anthraquinone*, $C_{14}H_8O_2$; this is then converted into a sulphonic acid or a bromo-compound, which by the action of alkalies yields alizarin. A half dozen other species of *Rubia* are similarly employed, and some of them are employed medicinally for disorders connected with the blood, probably in consideration of their color. *R. cordifolia* L. (*R. cordata* Thunb.) is called *Manjith*, *Tamra-valli*, and by other names, in India. *R. Munjistin* Roxb. is the Chinese *Si-ts'au-kan*. Three coloring-matters have been isolated from *R. Sikkimensis* Kurz., which are claimed to be distinct from those of madder.

Morinda (*Al-Dye*).—A red dye very similar to that of madder is prepared in the East Indies from the roots of a number of species of *Morinda*, especially *M. citrifolia* L. and the perhaps distinct species *M. tinctoria* Roxb. The coloring-matter is called *morindin*. The use of this dye is somewhat complicated, and is fully treated in *Agricult. Ledger*, 1895, No. 9, and 1896, No. 22. Articles dyed with it are said not to be attacked by insects. The leaves of *M. citrifolia* are used as an astringent, the fruit in hepatic disorders. The fruit of *M. Royoc* L., of tropical America, is used as a purgative; the leaves of *M. tomentosa* Heyne, of India, as a vulnerary, the bark of *M. bracteata* Roxb. as an anthelmintic, and the juice of the fruit and leaves of other species as antispasmodics.

Oldenlaudia umbellata L. (*Hedyotis Indica* R. et Sch.) yields the East Indian root *Ghé*, or *Chayavar*, from which a red dye is obtained, and which is also used medicinally, as are its leaves. The same is true of *O. lactea* DC., which has many local names in India. *O. dichotoma* Hook. is the *Papata* or *Kazuri*.

The root of *Mussœnda frondosa* L. is very largely employed in India, under many names and for many purposes, depending chiefly, it would appear, upon the saponin contained.

Triodia irritans R. Br. is supposed to be the plant the root of which yields *Spinifax* resin, used by the Australian natives for cementing arrow-heads. This is described as an exceedingly tough resin, of a dirty dark-bronze color, and a very persistent and disagreeable odor, slightly resembling beeswax.

Several species of *Rondeletia*, of tropical America, yield oleo-resins which are used as vulneraries.

Bothriospora corymbosa Hook. (*Evosmia c.* Schombk.), of Guiana, is said to be poisonous, and the same is true of the berries of *Kraussia coriacea* Sond., of Natal. The root of *Guettarda speciosa* L. is vesicant. That of *Plectronia parviflora* Bedd., of India, is used as an anthelmintic under the name *Kirni*. The very bitter bark of *Sarcocephalus esculentus* Lab., of west Africa, is used as a refrigerant and tonic under the name *Dundaki*, and is chewed like Coca. The wood is also used under the name *Nijmo*. The alkaloid *dundakine* has been isolated. Given hypodermically to frogs, it produces a paralytic or cataleptic condition, and kills by suspending respiration, without affecting the heart.

Nauclea inermis R. Br., related to *Ourouparia*, is used in the Soudan in the form of the leaf-infusion, as an anti-emetic and to allay rheumatic pain.

Several hundred additional species of Rubiaceæ have been recorded as in use medicinally.

RUBUS, *U. S.*—Blackberry.

Bramble, Finger-berry, E.; *Brambeeren*, G.; *Ronce noir, Ronce sauvage*, Fr. Cod.; *Zarzamora*, Sp.

The dried bark of the rhizome of *Rubus villosus* Ait., *R. nigrobaccus* Bailey, and *R. cuneifolius* Pursh. (Fam. *Rosaceæ*).

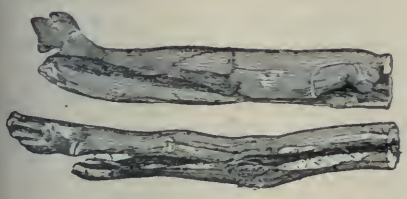
Blackberry bark is not official in any other pharmacopœia.

Origin.—The genus *Rubus* L. contains about 250 species, divided into two well-distinguished groups, the Raspberries, in which the mature fruit leaves the torus behind, and the Blackberries, in which the torus comes away as a part of the fruit. Most of the species belong to the latter group, and they are so closely related and so variable that their study presents very great difficulties. Recent researches have shown clearly that *Rubus villosus* does not occur at all in North America, the common high bush blackberry, which has long been so called, being *R. nigrobaccus*. *R. Canadensis* L. and *R. trivialis* Mx., heretofore named in the U. S. P. definition, are both low, or running blackberries, and the vertical habit of growth of the roots, and the thinness and fragility of their barks, effectually prevent collection. The European *R. villosus*, the American *R. nigrobaccus*, and especially *R. cuneifolius*, the very abundant Sand-blackberry of the Eastern and Southern States, all have long horizontal rhizomes, with a thick bark which slips off easily, in quills, after a longitudinal incision has been made upon one side. The blackberry plants are too well known to require description.

Description.—The drug is in elongated, tough, flexible quills from 3 to 6 Mm. ($\frac{1}{8}$–$\frac{1}{4}$ In.) in diameter, or in similar bands, the bark 1 to 2 Mm. ($\frac{1}{25}$–$\frac{1}{12}$ In.) thick; outer surface

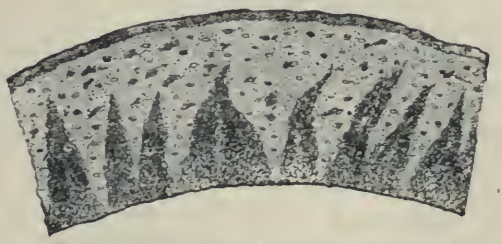
deep red brown or dark gray brown, occasionally blackish brown, smoothish or somewhat scaly; inner surface yellow or pale brownish, strongly and coarsely long straight-striate; fracture tough-fibrous; readily splitting; inodorous; taste strongly astringent and bitterish.

FIG. 350.



Rubus (Nat.).

FIG. 351.



Rubus villosus: transverse section through bark (× 15).

Constituents.—The important and active constituent of Blackberry root is from 10 to 20 per cent. of tannic and a little gallic acid. There is nearly 1 per cent. of the bitter glucoside *villosin*, apparently related to saponin, which can be extracted with water, but more readily with alcohol. It occurs in fine silky needles and is readily decomposed into *villosic acid* and sugar. About 7 per cent. of resin, a little volatile and fixed oil, wax, etc., also occur. An alkaloid has been reported, but probably does not exist.

Pharmaceutical Preparations.—FLUIDEXTRACT OF RUBUS, SYRUP OF RUBUS, U. S. P.

Action and Uses.—Blackberry and dewberry roots possess tonic and strongly astringent properties. They are favorite household remedies in the treatment of summer diarrhœas of children and adults. A decoction, made by boiling 1 ounce (30 Gm.) of the bark of the root in 1½ pints (720 Cc.) of water until 1 pint (480 Cc.) remains, is given in the dose of 1 to 2 ounces (30–60 Cc.) every 3 or 4 hours. Blackberry cordial is frequently used for the same purpose. The dose of the powdered root is from 20 to 30 grains (1.3–2.0 Gm.), of the fluidextract, 20 to 30 minims (1.3–2.0 Cc.), and of the syrup, 1 to 2 drachms (4–8 Cc.).

Allied Drugs.—The leaves of *Blackberry* and *Raspberry* (*Folia Rubi Idæi*), like those of many related plants (see ROSACEÆ), are used like Rubus, as intestinal astringents. They possess the advantage over the bark of containing large amounts of gum, which imparts rather distinct and in many cases superior properties. They are largely used as household remedies. Blackberry fruit, even when ripe, is more or less astringent, and its wine is highly valued for this property.

Rubus Idæus (*Raspberry; Himbeeren*, G.; *Framboise*, Fr. Cod.; *Frambuesa, Sanguesa*, Sp.) is the fresh ripe fruit of the cultivated European Raspberry, though the 1890 Pharmacopœia allowed the native red Raspberry (*R. strigosus* Mx.) and the native Black Raspberry or *Black cap* (*R. occidentalis* L.) to be used when the other is not obtainable. This fruit contains no distinctively medicinal constituent, and is valued solely for making a pleasant syrup to be used as a vehicle or adjuvant. Besides the water, raspberries contain 4.5 to 8.7 per cent. of insoluble matter, 4 to 8 per cent. of ash, and 7 to 8.5 per cent. of organic constituents, about one-half of which is sugar, one-fourth is malic and citric acids, and the remainder consists of proteids, pectin, etc. The odor is due to a volatile oil consisting of compound ethers, and when distilled with water the distillate separates a white flocculent stearopten. The only use of raspberries in medicine is for the preparation of an agreeable syrup.

RUMEX.—Rumex.

Radix rumicis, R. lapathi.—Dock, E.; *Grindwurz, Mengelwurz*, G.; *Patience*, Fr.; *Lapato*, Sp.

The dried root of *Rumex crispus* L. and of other species of Rumex (Fam. *Polygonaceæ*).

Origin.—The genus *Rumex* L. contains more than 100 species, mostly of the north-temperate zone, through which they are rather evenly distributed. Only a few of them have been employed under the official title, and probably none other than the two following to any appreciable extent. *R. crispus* L. is the *Curled, Curly*, or *Narrow-leaved dock*, and is preferred. It is a native of Europe and Asia and very exten-

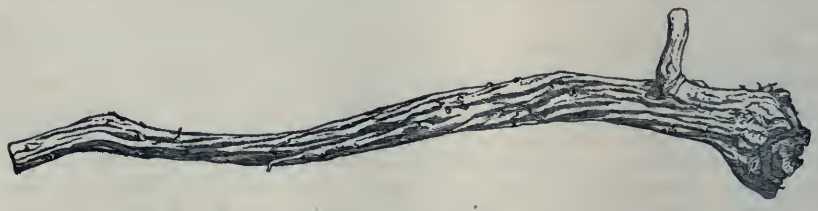
sively naturalized in North America as a field and roadside weed. Its lowermost leaves are often more than 1 foot in length, linear-lanceolate and strongly crisped and wavy-margined. The upper leaves are similar but successively smaller. The erect stem is rather slender, coarsely angled, and the inflorescence a large, slender, terminal panicle, which at length becomes a dense mass of rusty-brown, 3-winged capsules, each about 3 to 4 Mm. ($\frac{1}{8}$–$\frac{1}{6}$ In.) long. These leaves are largely consumed in the spring as a pot-herb, and exercise an excellent laxative and antiscorbutic effect.

R. obtusifolius L. is the *Yellow, Common, Broad-leaved* or *Blunt-leaved, Bitter* or *Butter dock.* It has the same nativity and range as the last, but is far more abundant along roads, and in cultivated ground, and is more largely used in European countries. It is well distinguished by its broad, blunt, nearly flat leaves. Dock-root should be collected in autumn.

Description.—From 20 to 30 Cm. (8–12 In.) long and 1 to 2 Cm. ($\frac{2}{5}$–$\frac{4}{5}$ In.) thick, nearly simple, tapering or somewhat fusiform, with few if any rootlets, finely annulate above, very strongly wrinkled and usually twisted, deep red brown, marked with small indented, often transversely elongated, scars; fracture short but somewhat splintery-fibrous; transverse section whitish, becoming yellow, the bark thick, the wood finely radiate in the outer portion; odor slight, peculiar; taste bitter and astringent.

Rumex obtusifolius is darker, and usually divides near the crown into a number of smaller parallel branches, with more adhering rootlets.

FIG. 352.



Rumex crispus (½ Nat.).

Constituents.—The chemical constituents of dock are closely similar in kind to those of *Rheum*, though the relative proportion of the astringent principles is much greater in Dock. The *rumicin* and *lapathin* of earlier investigators were regarded by von Tann as identical with chrysophanic acid, but this is probably incorrect, since Hesse finds the rumicin of *R. Nepalensis* Wall. ($C_{15}H_{10}O_4$) to be isomeric with chrysophanic acid, but with a different melting-point, and that of Dock is probably the same. With the *rumicin*, occur nepodin and lapodin. *Nepodin* ($C_{18}H_{16}O_4$) occurs in long greenish prisms, melting at 158° C. (314.4° F.). *Lapodin* ($C_{18}H_{16}O_5$) occurs in fine crystals.

Action and Uses.—Yellow dock possesses astringent and tonic virtues allied to those of rhubarb. It is not extensively employed at the present time, but was formerly an esteemed remedy, given internally and applied locally in scabies and chronic cutaneous eruptions, especially those of a scrofulous nature. Some species of Rumex were used in indigestion and hepatic congestion. A decoction, made by boiling 2 ounces (60 Gm.) of the fresh root, or 1 ounce (30 Gm.) of the dried root in 1 pint (480 Cc.) of water, was given in 2-ounce (60 Cc.) doses. For external application the root was made into cataplasm, ointment, or decoction.

Other Species.—*R. sanguineus* L., the *Bloody* or *Red-veined dock, Blood-wort* or *Olcott-root,* and *R. aquaticus* L., the *Water dock,* both of Europe, the former somewhat naturalized in the United States, are astringent, especially their fruits. *R. alpinus* L., of Europe and Asia, is compared with rhubarb for its bitterness and astringency. *R. acutus* L., of Europe, has been much used in pulp as a dressing for foul ulcers.

R. acetosa L. (*Acetosa magna* Gilib.; *A. officinalis* Gueld.; *A. pratensis* Mill.), the *Green, Meadow, Cock, Ginger,* or *Kitchen sorrel, Sour-grass, Sharp dock, Ginger sauce* or *Sour sauce, Sourock, Sauerampfer* (G.), *Oseille commune* (Fr.), *Acedera* (Sp.); *R. Acetosella* L. (*Acetosa A.* Mill.; *Acetosella vulgaris* Four.), the *Horse, Sheep, Cow, Field, Mountain, Red-top, Food,* or *Gentleman's sorrel, Red-weed* or *Ranty-tanty;* and *R. scutatus* L. (*Acetosa s.* Mill.), the *French sorrel,* represent a different class, being small herbs with slender creeping rhizomes and strongly acid herbage like that of *Garden pieplant.* They are natives of Europe and the two former, especially the second named, are among the worst meadow-weeds of the United

States. The leaves, the part used, contain oxalic acid as potassium binoxalate, and oxalic acid is also found in the rhizome when young.

R. hymenosepalus Torr. (*Canaigre, Wild* or *Texas Pieplant*), very common through the southwestern United States and adjacent Mexico, and becoming very extensively cultivated for tanning purposes, forms a sort of connecting link between the two groups already considered. Its leaves are acid and its roots highly astringent, containing from 25 to 40 per cent. of tannin, together with a large amount of starch.

Oxalis and Oxalidaceæ.—This genus and family may be considered in connection with the acid-leaved *Rumices*, since they owe similar refrigerant and antiscorbutic properties to the same constituent, potassium binoxalate (Salt of Sorrel). The species understood by the name *Oxalis*, is *O. Acetosella* L. (*Oxys A.* Scop.), the *Wood-sorrel* or *Wood-sour, Ladies' Sour-grass, Clover sour, Sleeping clover, Cuckoo-sour* or *Cuckoo's bread, Laverocks, Shamrock, Sauerklee* or *Hasenklee* (G.), *Surel* or *Alleluia* (Fr.), *Acerdilla* or *Soayol* (Sp.). It is a low and tender, pubescent herb of deeply shaded forests of North America, Europe, Asia, and northern Africa. It grows from a scaly rhizome which sends up long-petioled, stipulate, trifoliolate leaves, the leaflets broadly obcordate, and still longer scapes, each bearing a single, very pretty, white, purple-veined, bell-shaped flower. Several other species are common little weeds, with branched stems and yellow flowers. They possess a similar herbage and can be similarly employed. A species of Brazil is there used as a refrigerant under the Portuguese name *Raiz de azedinha grama*. Many species of *Oxalis* are cultivated in houses and gardens for ornament. Of the 250 to 300 species, some, of the tropics, become very large, their succulent trailing stems several yards in length and an inch or two in thickness. They usually have acid properties.

Averrhoa Carambola L. and *A. Bilimbi* L. are small trees of the Orient, which yield very curious, crisply succulent, finely acid fruits, the *Bilimbi* and *Averrhoa* (*Wo-lien-tsze* of the Chinese), used for their refrigerant properties, and to some extent for preserves. Under the Tagala name *Kamias*, also *Bilimbin*, these fruits are eaten and preserved in the Philippines, and are used to remove ink and rust stains.

RUTA.—Rue.

Rue, Fr. Cod.; *Garden rue, Herb-of-grace*, E.; *Raute*, G.; *Ruda*, Sp.

The leaves of *Ruta graveolens*, L. (Fam. *Rutaceæ*).

Origin and Description.—The Rue plant is a perennial herb, or sometimes a weak undershrub, of southern Europe, and is often cultivated there and in other countries as a domestic medicinal herb. The lower leaves are long-petioled, the twice or thrice pinnately compound blades 7 to 15 Cm (3-6 In.) long, broadly triangular-ovate, smooth, grayish- or yellowish-brown, the ultimate divisions from oblong-obovate to spatulate, more or less wedge-shaped at the base, rounded at the summit, usually somewhat crenate, thickish, glandular and pellucid-dotted as seen against the light. The upper leaves become more shortly petioled, smaller, narrower and less compound. The yellowish flowers occur in terminal corymbs. The capsules are 4- or 5-lobed and contain numerous angularly ovoid blackish seeds. The odor is peculiar, heavy and rather disagreeable, the taste aromatic, bitter and acrid.

FIG. 353.

Rue leaf (¾ Nat.).

Constituents.—The important constituent of Rue is a small fraction of 1 per cent. (0.06 per cent., according to Gildemeister and Hoffmann) of a volatile oil which is colorless or more or less yellow and is said to be the lightest of all volatile oils (specific gravity, 0.833 to 0.840). It is extremely unpleasant and odorous unless greatly diluted, when it is less unpleasant. It has been found to contain a peculiar ketone, but its composition is mostly unknown. It was official in the U. S. Pharmacopœia from 1870 to 1890. Rue also contains the glucoside *rutin* (*rutic* or *rutinic* acid, $C_{42}H_{50}O_{25}$), which is yellow and crystalline and is believed to be iden-

tical with the barosmin of Buchu. It occurs also in Capers. The decomposition of rutin is the source of *quercetin*, which also occurs in Rue in large amounts. There is also considerable sugar, and a volatile alkaloid has been reported, though its presence is doubtful.

Action and Uses.—Locally applied, rue is an irritant and vesicant.

Internally it is stimulant, carminative, and emmenagogue. In large doses it is an irritant poison, producing severe gastro-enteritis, vomiting, abdominal pain and distention, bloody stools, strangury, and epileptiform convulsions, rarely death. In moderate quantity it may be given as a uterine stimulant in menorrhagia, metrorrhagia, and amenorrhœa due to atonic conditions of the uterus, but its employment as an abortifacient is attended with great danger to the mother. It is sometimes used for the removal of round worms, but is not a safe anthelminitic. Rue is given in the dose of 15 to 30 grains (1–2 Gm.), usually in infusion. The dose of the oil is from 3 to 6 minims (0.20–0.40 Cc.), best given in capsule.

RUTACEÆ.—The Rue Family.

The *Rutaceæ*, including the *Aurantiaceæ* as a subfamiily, comprises, according to Engler, about 111 genera and nearly 1000 species, almost all tropical, a very few extending into cool-temperate regions. The important Citrus fruits pertain to the subfamily named above. These have been considered under LIMONIS, AURANTIA, etc. Except for these, economic interest in the family is almost wholly medical, and is very great. As separate articles, we have considered the drugs CUSPARIA, XANTHOXYLUM, PILOCARPUS, and BUCHU, which fairly represent the constituents and properties of the family. The former are most generally volatile oils, indicated by the pellucid dots seen when the leaves are held against the light. They are commonly, if not generally, associated with resins, which are themselves often active. Both alkaloids and glucosides are very common. The active constituents of the drugs are in general highly diffusible and act powerfully on the glandular system, both secretory and excretory, so that the drugs are largely used as alteratives. A very large number of them are used as febrifuges, antiperiodics, and bitter tonics. It is rather remarkable that a family so rich in native and domestic remedies, and these of such marked activity, should be so sparingly represented in professional materia medica.

Ptelea or *Shrubby trefoil* (*Wafer* or *Stinking-ash, Hop-, Quinine-*, or *Sang-tree, Wing-seed*, etc., E.; *Hopfenbaum, Kleebaum*, G.; *Orme à trois feuilles*, Fr.) is usually understood as the bark, especially of the root, of *Ptelea trifoliata* L., though the leaves and fruit are also somewhat employed. The plant is a handsome shrub or small tree of eastern North America, extending into southern Canada and northern Mexico. The leaves, downy when young, like the twigs, are alternate, petiolate, light-green, and trifoliolate, with sessile, pointed, indistinctly serrate, and finely pellucid-punctate leaflets, of which the lateral ones are obliquely ovate, and very uneven toward the base, the outer half being broadest, while the larger terminal one is elliptic or obovate and wedge-shaped at the base. They are from 7 to 12 Cm. (3–5 In.) long, when broken exhale a rather unpleasant odor, and have a bitter and somewhat astringent taste. The small greenish-white polygamous flowers are in compound terminal cymes, have a disagreeable odor, and are followed by a flat orbicular fruit, which is 2-celled and 2-seeded, and is surrounded by a circular membranous and slightly emarginate wing, the whole fruit being about 2 Cm. ($\frac{4}{5}$ In.) in diameter and of a pleasant hop-like flavor. The bark occurs in fragments and irregular quills of a brown color, longitudinally wrinkled, lighter and smooth on the inner surface, breaks with a short fracture, and has a bitter and pungent taste. The bark contains at least 3 active constituents, namely, a powerful volatile oil, a soft acrid resin, and an alkaloid. The latter is probably the same as that found in various other plants of the family and supposed to be berberine; but it is quite likely that it will be found distinct therefrom. There are also an inert resin, fat, gum, potassium nitrate, and the alkaloid *arginine* ($C_6H_{14}N_4O_2$).

Fraxinella, or *White fraxinella* (*Dittander, Bastard dittany, Garden ginger*, E.; *Weisse Dictamwurzel, Escherwurzel, Specht wurzel*, G.), is the root of *Dictamnus albus* L. (*D. Fraxinella* Pers.), a tall perennial herb or soft shrub of southern Europe and adjacent Asia. It is an object of curiosity because of a slight explosion of volatile oil which takes place when a lighted match is brought near to its stem. It is rich in volatile oil and bitter constituent, and is an old-time remedy, used as a diaphoretic, diuretic, emmenagogue, and bitter tonic.

The following domestic and native drugs are worthy of investigation:

Toddalia aculeata Pers. yields one of the roots which have been called *Lopez root*. It is used in the East Indies as a febrifuge and in dysentery, and has been occasionally seen in commerce. The leaves of *Orixa japonica* Thunb. (*Sijo-kus-chi-zu*, Chinese) as well as the root (*Si-you-san*, Chin.; *Kokusagi, Haneboku*, Jap.) are used as antiperiodics and insecticides. The bark is said to contain berberine. The bark of the Australian tree *Melicopa erythrococca*

Benth. contains an alkaloid which is a heart poison. *Boronia rhomboidea* Hook., of New South Wales, is anthelmintic. The bark of *Lunasia amara* Blanco (*Rabelasia philippinensis* Planch.; *Mytilococcus zollingeri* Miq.) contains the poisonous glucoside *rabelaisin*, and is used as an arrow poison in the Philippines. The leaves of various species of *Agathosma* and *Coleonema*, of the Cape region, are used like Buchu, and those of *Adenandra fragrans* R. et S., of the same region, are used as a tea-substitute. *Geijera salicifolia* Schott. yields a kind of copaiba in New South Wales. Venezuelan Sandal-wood is obtained from *Spiranthera odoratissima* St. Hil. *Ticorea febrifuga* St. Hil. yields the *Tres folhas brancas* bark of Brazil, used as a cinchona-substitute, as is that of *Hortia brasiliana* Vand. Elemi-like oleoresins are obtained from various species of *Amyris*, especially *A. hexandra* Ham., of the West Indies. *Clausena excavata* Burm. yields the important Chinese drug *Hwang-p'i-kwo*.

Resedaceæ.—This little family, of 6 genera and about 66 species, nearly all in the genus *Reseda*, though not very closely related to the *Rutaceæ*, is much like them in properties. The family is represented in medicine almost wholly by several species of *Reseda* or *Mignonette*. *R. odorata* L. is the *Common* or *Garden mignonette*. *R. luteola* L. is the *Dyers' mignonette*, *weed*, or *rocket*, *Italian* or *Yellow rocket* or *Wild-wood* (*Gelbkraut*, *Wau*, or *Waid*, G.). As its common names indicate, it is used for coloring purposes. It contains the glucoside *luteolin*, and yields the yellow dye *gaude*. It is also used as a diuretic and diaphoretic.

S.

SABADILLA.—Cevadilla.

Cévadille, Fr. Cod.; *Indian barley-caustic*, E.; *Sabadillsamen, Läusekörner*, G.; *Cebadilla* (or *Cevadilla*), Sp.

The dried ripe seed of *Asagræa officinalis* (Ch. et Sch.) Lindl. (*Veratrum o.*—Ch. et Sch.; *Schœnocaulon o.*—Gray; *Helonias o.*—Don; *Sabadilla o.*—Brandt.—Fam. *Liliaceæ*).

Origin.—The Sabadilla plant is a poisonous bulbous perennial, indigenous to the tropical coast of the Gulf of Mexico. The seeds are produced, 2 to 6 in a cell, in a small 3-celled capsule, in which they are commonly exported from Mexico.

FIG. 354.

Asagræa officinalis, *Lindley:* fruit, nat. size; seed and longitudinal section magnified.

Description.—From 5 to 8 Mm. ($\frac{1}{5}$–$\frac{1}{3}$ In.) long, narrowly lanceolate or lance-oblong, the smaller end terete and tapering, the larger somewhat shovel-shaped, with a short ridge running the length of the hollowed side; dark red brown or brownish black, strongly wrinkled; endosperm whitish and oily, and containing at the base a small linear embryo; nearly odorless, but the powder highly sternutatory; taste very bitter and persistently acrid.

Constituents.—The important constituent of sabadilla is about 1 per cent. of several alkaloids (see VERATRINA), which exist with fat, wax, gum, coloring-matter, and *sabadillic* or *cevadic acid* and *veratric acid* ($C_9H_{10}O_4$), the latter crystalline, soluble in alcohol and hot water, fusible and sublimable, like the former.

Action and Uses.—Sabadilla is of interest medicinally as the source of veratrine. It was employed as a tæniacide in the dose of 5 to 20 grains (0.30–1.30 Gm.), but its administration was occasionally productive of such severe vomiting and drastic purging that it has been discarded as a remedy in internal medicine. Several deaths from its employment are recorded. It may be used in ointment or decoction to destroy body lice and other vermin, and as an application in scabies.

SABAL, *U. S.*—Saw-palmetto.

The partially dried ripe fruit of *Serenoa serrulata* (R. et S.) Hook. f. (*Sabal s.*—R. et S.; *Brahea s.*—Wendl.; *Chamærops s.*—Pursh.—Fam. *Palmæ*).

Origin.—From a stout, evergreen shrub, with a large underground trunk, orbiculate leaves 3 to 7 Dm. broad, with cleft segments, borne on long, stout, spiny-toothed petioles, and paniculate inflorescence and fruit. It is abundant along the southern Atlantic and Gulf coasts of the United States. The bark and wood of the trunk constitute an important tanning agent. The ripe fruit is partially dried, preferably in a fruit-evaporator, and marketed, chiefly in barrels. It is considerably employed in Florida as a food for fowls.

Description.—Fruit 1.2 to 2.5 Cm. long and about half as thick, oblong-ovoid, of a deep red brown or blackish and smooth, except for some wrinkles caused in drying. The epicarp is thickish and strongly cutinized, the sarcocarp juicy and somewhat stringy, the putamen thin and smooth, the seed elliptical oblong, a little flattened on one side, and hard and bony. The odor is peculiar, cheesy, and not very agreeable, the taste sweetish, but slightly acrid and not agreeable.

Constituents.—These fruits contain a large amount of glucose, volatile and fixed oil, resin, and a very little alkaloid. The volatile oil is present in the pulp, and is in very small amount, though yielded by the fresh fruits to the extent of more than 1 per cent. It has a specific gravity of about 0.865, is of a greenish to brownish color, and consists of caproic, caprylic, capric, lauric, palmitic, and oleic acids and their esters.

Uses.—Sabal is thought to possess sedative, tonic, diuretic, and expectorant properties, and has been recommended in the treatment of subacute and chronic inflammations of the genito-urinary tract, chronic bronchitis, pulmonary tuberculosis, and atonic impotence. A fluidextract may be employed in doses of from 1 to 2 fluidrachms (3.7–7.4 Cc.).

SABINA, *U. S.*—Savin (Savine).

Sabinæ cacumina, Summitates (*Herba*) *sabinæ.*—*Savin-tops, E.*; *Sadebaumspitzen, Sevenkraut,* G.; *Sabine,* Fr. Cod.; *Sabina,* Sp.

The tops of *Juniperus Sabina* L. (*Sabina officinalis* Garche.—Fam. *Pinaceæ*).

Origin.—A low, spreading shrubby cedar-tree, bearing a semi-pendulous fruit, somewhat larger than that of the common cedar. It is widely distributed through the north-temperate zone, extending southward in North America to the northern United States. The drug comes chiefly from central Europe.

Fig. 355.

Branch of savin.

Description.—As met with in commerce, savin is in small and thin subquadrangular pieces, consisting of slender twigs, which are densely covered with minute, scale-like, imbricate leaves, arranged alternately in decussating pairs. The leaves are rhomboid-lanceolate, rather obtuse, and closely appressed, and on the back have a shallow groove containing a gland, which is mostly oblong in shape. Older leaves are more pointed and more or less spreading. Savin has a persistent somewhat terebinthinate odor, which is stronger after bruising the branchlets; the taste is nauseous, resinous, and bitter. The drug is frequently mixed with some fruits which are about 5 Mm. (¼ In.) in diameter, globular, but more or less shrivelled, blackish-blue or brownish, contain usually 2 seeds, and have odor and taste similar to but stronger than the branchlets.

Constituents.—The important constituent of Savin is its volatile oil (see Oleum Sabinæ), of which the yield is variously stated at from 4 to 5 per cent. and as high as 10 per cent. With this are tannin, a large amount of resin, and salts of potassium and calcium. The uses of the drug depend wholly upon its volatile oil.

Pharmaceutical Preparation.—Fluidextract of Savin, U. S. P.

Action and Uses.—Savin possesses irritant and stimulant properties. The oil of savin applied to the skin may cause vesication. Medicinal doses produce a sense of warmth in the stomach, stimulate cardiac action and the flow of bronchial secretion, and act as a stimulant to the uterine tissues. It is employed chiefly in amenorrhœa, painful menstruation, and menorrhagia dependent upon atony of the uterus, but is never to be used if congestion of the pelvic viscera exists, or in a condition of general plethora. It must be given cautiously if at all in pregnancy. Its administration in sufficient quantity to cause abortion is attended by alarming symptoms, violent vomiting and purging, strangury, and not infrequently collapse and death. In infusion or decoction, savin has been esteemed, especially by the Germans, as a remedy to be given internally and applied locally in chronic rheumatism and gout. In powder, slightly moistened, it has been used to remove venereal warts and condylomata, and as a stimulating application to indolent ulcers. The dose of savin is from 5 to 10 grains (0.30–0.60 Gm.) in powder, infusion, or decoction. The oil in the dose of from 2 to 5 minims (0.10–0.30 Cc.) is generally employed, dispensed in capsule or emulsion.

Other Junipers and Cedars.—The genus *Juniperus*, L., comprises some 30 species of evergreen trees and shrubs, more or less similar to Savin and with fruits like those of Juniperus. The genus, as is true of most of the species, is widely and abundantly distributed through the northern hemisphere. *J. communis* has been considered under the title Juniperus; *J. Oxycedrus*, under Oleum Cadinum. *J. Bermudiana* L., of the West Indies, is known as the Bermuda pencil cedar. Various other species have also been distilled for their volatile oils. Next to those named above, the most important is the following:

Juniperus Virginiana L., the *Red, Pencil, Virginia* or *Carolina cedar,* E.; *Cèdre de Virginie,* Fr.; *Virginische Ceder, Rothe Ceder,* Ger., is abundant throughout almost the entire eastern and central parts of North America. Its branchlets quite closely resemble those of

Savin, and there has indeed been considerable difference of opinion as to whether these are specifically distinct. The branches which bear the fruit are not recurved as are those of Sabina, and the leaves are somewhat narrower than those of the latter. The constituents of these twigs are almost identical with those of Savin.

The oil of the wood yields *Cedrene camphor* ($C_{15}H_{26}O$), obtained by congealing and expression. The liquid portion thus resulting is *cedrene* ($C_{15}H_{24}$), its odor distinct from and stronger that that of the camphor and its taste at length peppery.

"*Cedar*" is a name generally equivalent to Juniper, but it has also been applied to the following, as well as to other less important, plants: *Cedrela odorata* L. (*C. Cedro* L. f.; *Cedrus o.* Mill.—Fam. *Meliaceæ*), the *Sweet tropical* or *Spanish red cedar*, or *Cigar-box cedar*, also known by a number of local tropical American geographical names. It yields *Oleum Cedrelæ*. The Australian species is *C. Toona* Roxb., and is known as *Toon tree* or *Indian mahogany*. It yields the Toon-tree gum. *Thuja occidentalis* (see THUJA), *Libocedrus decurrens* Torr., the *Post* or *Incense cedar* of our Pacific coast, and *Chamæcyparis thyoides* (L.) B. S. P. (*Cupressus t.* L.; *Thuja sphæroidalis* Rich.), the *Spanish* or *Swamp cedar* of the southeastern United States, are all known as White Cedar, as are some related species in other sections. *Cedrus Cedrus* (L.) Lyons (*Pinus C.* L.; *C. Libani* Barrel; *C. Libanotica* Link; *Abies C.* Poir.) is the *Cedar of Lebanon*. A mistake among the different coniferæ called cedars is not serious, since they exhibit a great general similarity in constituents and properties.

SACCHARUM, *U. S., P. G.*—Sugar.

Saccharum purificatum, Br.—*Refined sugar, Cane-sugar, Sucrose*, E.; *Sucre, Sucre de canne*, Fr.; *Zucker, Rohrzucker*, G.; *Azúcar, Azúcar de caña*, Sp.

The refined sugar obtained from *Saccharum officinarum* L. and from various species or varieties of sorghum (Fam. *Gramineæ*); also from one or more varieties of *Beta vulgaris* L. (Fam. *Chenopodiaceæ*).—U. S. A crystallized sugar, obtained from the juice of the sugar-cane.—Br.

Formula, $C_{12}H_{22}O_{11}$. Molecular weight, 339.60.

Origin.—The sugar-cane appears to have been indigenous to India and other parts of southern and eastern Asia, and has been cultivated from time immemorial. At present it is not known in the wild state, but it is raised in most tropical and subtropical countries, and in many of them for the production of sugar. It is a perennial, and produces a stem which is from 2.4 to 3.6 M. (8–12 Ft.) high, 2 to 5 Cm. (1–2 In.) thick, cylindrical, jointed, and, with the exception of the flowering tops, which are hollow, filled with a juicy pith. The leaves are from 1.2 to 1.5 M. (4–5 Ft.) long, 5 Cm. (2 In.) wide, and linear; and the flowering panicles large, pyramidal, and with spreading branches. Several varieties are known, differing chiefly in the color and hairiness of the stem. *Saccharum chinense* Roxb., which is the principal species cultivated in China, has a slender erect panicle, and is probably a distinct species. Cane-sugar is present in a large number of grasses, particularly in those having a rather thick stem, such as *Sorghum saccharatum* Pers., *S. Holcus saccharatus* L., *Zea Mays* L., and others. From the thorough researches of H. Leplay, published in 1882, it appears that the sugar is produced in the leaves and transferred to the stem, where it gradually accumulates, and when the fruit begins to develop it is conveyed to the grain, where it is converted into starch, the sugar at the same time disappearing from the leaves and diminishing very materially in the stem. It is also present in the juice of the different species of maple, birch, palm, and other trees, and in many fleshy roots, prominent among which is a cultivated variety of *Beta vulgaris* L., or *sugar-beet*, which is largely used in Europe in preparing sugar.

Preparation.—Recently collected sugar-cane yields by crushing and expressing about 80 per cent. of juice, which contains from 78 to 84 per cent. of water, 16 to 21 per cent. of sugar, 0.3 to 0.4 per cent. of mucilaginous, resinous, fatty, and albuminous matters, and nearly the same amount of salts. The juice is a grayish, turbid, sweet liquid, which is clarified by heating, a little lime being at the same time added for the purpose of neutralizing free acid; it is then concentrated by rapid evaporation in open pans, transferred to coolers, where it is frequently stirred, and afterward into casks perforated at the bottom and arranged in such a manner that the liquid portion may drain off and be collected in suitable tanks. The granular solid product thus obtained constitutes the *raw* or *muscovado sugar* of commerce; the liquid portion is known as *treacle* or *molasses*. Raw sugar is refined by dissolving it in water, the solution is heated with

blood, the impurities are skimmed off, and the liquid is filtered through recently burned granular animal charcoal. The clear and colorless filtrate is concentrated in a vacuum-pan, and when of sufficient density run off into conical molds, the narrow orifice of which is closed by a plug. It solidifies as a dense crystalline mass, which is drained by the removal of the plug, and freed from the remaining colored mother-liquor by percolating through it a concentrated solution of pure sugar, after which it is dried and sent into commerce as *refined* or *loaf sugar*. By concentrating the mother-liquors they are made to yield more sugar of an inferior grade, until finally a thick syrupy liquid is obtained, which refuses to crystallize, and is known as *sugar-house molasses*, and in England as treacle.

The method of obtaining sugar from the sugar-beet is very similar to that described, but is attended with greater difficulties, owing to the presence of larger quantities of proteids and other foreign constituents. Sugar-beets contain about 9 to 19 per cent. and yield about 9 per cent. of cane-sugar.

Sugar-cane was practically the sole supply of sucrose until the discovery of sucrose by Andreas Sigismund Marggraf in 1747 in beets opened a new source, which, however, was not commercially successful until the application of improved methods about 1825. By scientific cultivation the original forage beet with a sugar content of 6 per cent. has been developed into the present sugar beet containing as high as 20 per cent., and the actual sugar crop from this source at the present time is equal to, if not greater, than that from the sugar-cane, and in 1901 reached the enormous total of 6,750,478 tons in Europe alone.

The sugar crops of the world during 1901, 1902, 1903, and 1904 are estimated as follows (Willet & Gray, Dec. 15, 1904):

	1904-5.	1903-4.	1902-3.	1901-2.	
Cane-sugar	4,607,000	4,251,699	4,149,632	4,081,509	tons.
European beet-sugar	4,690,000	5,852,043	5,561,257	6,750,478	"
U. S. beet-sugar	191,000	208,135	195,463	163,126	"
Total	9,488,000	10,311,877	9,906,352	10,995,113	"

The beet-sugar crop in 1892 amounted to only 10,000 tons, and to 25,000 tons in 1898.

The consumption of sugar in the United States during the past two years is as follows (Willet & Gray):

	1904.	1903.	
Total of all sugars from all sources	2,767,162	2,549,643	tons.
Consisting of domestic cane	323,646	292,800	"
Consisting of domestic beet	170,135	247,563	"
Consisting of maple	12,000	5,150	"
Total consumption of domestic sugars	521,094	567,038	"
Total consumption of foreign cane-sugar	2,137,036	1,968,946	"
Total consumption of foreign raw beet	102,194	9,028	"
Total consumption of foreign refined beet	6,838	4,631	"
Total from foreign countries and insular possessions	2,246,068	1,982,605	"
Of which from Hawaii	330,745	357,850	"
Of which from Porto Rico	116,942	85,989	"
Of which from Philippine Islands	22,100	29,947	"

Properties.—Sugar occurs in white, dry, hard, distinctly crystalline granules, odorless, and having a purely sweet taste. It is permanent in the air, and soluble at 25° C. (77° F.) in 0.46 part of water and in 137.2 parts of alcohol; also soluble in 0.2 part of boiling water and in 28 parts of boiling alcohol, and in 80 parts of boiling absolute alcohol, but insoluble in ether, chloroform, and carbon disulphide. Its aqueous solution, saturated at 25° C. (77° F.), has a specific gravity of about 1.340, is miscible with water in all proportions, should be colorless, and is dextrogyrate. The aqueous and alcoholic solutions of sugar are neutral to litmus-paper.—U. S. Refined sugar is also seen in commerce broken into small pieces or lumps, known as crushed sugar, and in regular cubes, known as cut-loaf sugar, which are hard and have a granular crystalline texture and a pure white color. Somewhat inferior kinds of sugar are softer, and those having a yellowish tint are often artificially improved in appearance by adding, while crystallizing, a minute quantity of blue pigment, like ultramarine, with the view of neutralizing the objectionable tint and making the sugar appear whiter; such sugar will

yield a yellowish solution with water, and on standing will gradually separate the pigment. Sugar may be obtained in large transparent rhombic prisms, known as *rock candy, saccharum candidum*, which does not differ from lump sugar except that this is in crystalline masses from disturbed crystallization. Sugar has the specific gravity 1.58 (Kopp), and dissolves at ordinary temperatures in one-half its weight of water, yielding a dense, sweet, and colorless liquid known as syrup; saturated at 15° C. (59° F.) such a solution contains 66 per cent. of sugar, and this has the density 1.345082 (Michel and Kraft). At the boiling-point sugar dissolves in water almost in all proportions. At 15° C. (59° F.) 1 part of sugar dissolves in 2 parts of 50 per cent. alcohol, in 7.7 parts of 75 per cent. alcohol, in 14.7 parts of 80 per cent. alcohol, in 31.6 parts of 85 per cent. alcohol, in 175 parts of 92 per cent. alcohol, and in 228 parts of methyl alcohol of the same strength (Casamajor). Sugar dissolves also in glycerin, the solubility being increased on dilution with water. It combines with sodium chloride, yielding deliquescent crystals which contain 14.9 per cent. of that salt. Definite compounds have likewise been obtained with several other salts and with alkalies and alkaline earths (see SYRUPUS CALCIS).

The saccharates of barium and strontium are difficultly soluble. A saccharate of calcium is in commercial use under the name of "Viscogen" for stiffening or giving body to milk and cream.

When sugar is heated to 160° C. (320° F.) it melts without losing in weight, and congeals on cooling to a transparent amorphous yellowish mass known as *barley sugar, saccharum hordeatum*, which becomes gradually opaque on the surface from the formation of minute crystals. If sugar is kept in the melted state between 160° and 170° C. (320° and 338° F.) for a short time, it is converted into a deliquescent mixture of *glucose* and *levulosan;* $C_{12}H_{22}O_{11}$ yields $C_6H_{12}O_6 + C_6H_{10}O_5$; the latter is not fermentable until after it has been boiled with water or dilute acids. When heated to between 180° and 200° C. (356° and 392° F.) sugar turns brown, evolves a peculiar odor, and is converted into *caramel*, $C_{12}H_{18}O_9$, parting at the same time with 2 molecules of water; the pure product of this composition, *caramelan*, was obtained colorless by Gelis (1862). Caramel may be prepared in the same manner from inferior qualities of sugar, from molasses, and from glucose, and the conversion is hastened in the presence of small quantities of alkalies; the addition of a little ammonium carbonate, which is again volatilized by the heat, is of service, for the reason stated. Subjected to dry distillation sugar yields aldehyde, acetone, acetic acid, tarry products and carbon dioxide, carbonic oxide and marsh gas. According to Lassaigne, iodine heated with a solution of sugar is converted into hydriodic acid. Sugar is not directly fermentable, but under the influence of ferments, as well as of dilute acids, cane-sugar is converted into *invert-sugar*, which is a mixture of equal parts of *dextrose* and *levulose*, and is then fermentable. *Invertin* or *invertase*, the enzyme of yeast, inverts sucrose, but not milk-sugar. The inversion of sugar takes place slowly on boiling with water, but cold aqueous solutions keep unaltered for a long time if kept free from germs. Under the same conditions, according to the investigations of Kreusler, Lemoine, and others, light does not exert the inverting effect reported by Raoul (1871). Strong mineral acids quickly invert sucrose. For analytical purposes a 10 to 20 per cent. sugar solution is mixed with 10 per cent. of its volume of concentrated hydrochloric acid, and the mixture heated to 67° C. (152.6° F.). Nitric acid inverts sucrose, and when heated with it produces saccharic, racemic, tartaric, and oxalic acids. Solutions of sucrose are strongly dextrorotatory, but after inversion lævorotatory. Its specific angle of rotation $= +66.5$. It does not reduce Fehling's Solution direct, but does after inversion.

Tests.—The purity of cane-sugar is ascertained by the physical properties described above, and by its complete solubility in water and alcohol. "Both the aqueous and alcoholic solutions of sugar should be clear and transparent. When kept in large, well-closed, and completely filled bottles they should not deposit a sediment on long standing (absence of insoluble salts, ultramarine, Prussian blue, etc.). If 1 Gm. of sugar be dissolved in 10 Cc. of boiling water, the solution mixed with 4 or 5 drops of silver nitrate test-solution, then about 2 Cc. of ammonia-water added, and the liquid quickly brought to the boiling-point, not more than a slight coloration, and no black precipitate, should appear in the liquid after standing at rest for 5 minutes (absence of glucose and of more than a slight amount of inverted sugar)."—U. S. "Aqueous and alcoholic solutions of sugar should have no effect on litmus-paper. The aqueous solu-

tion (1 to 20) should give no turbidity with hydrogen sulphide solution, and give at most a slight opalescence with test-solutions of ammonium oxalate, silver nitrate, or barium chloride."—P. G. "Refined sugar should yield no reaction with the test for calcium, chlorides, and sulphates. When sugar dissolved in half its weight of water is heated to about 82.2° C. (180° F.) with solution of potassio-cupric tartrate or with solution of copper sulphate and excess of solution of potassium hydroxide, there should not result more than a trace of a red or yellowish precipitate (absence of glucose)."—Br.

Action and Uses.—In small quantity sugar is demulcent and slightly sedative to the respiratory mucous membrane. A certain aperient effect is produced by cane-sugar if taken in large quantity, and a diuretic effect by glucose or grape sugar. As a food product sugar, like other hydrocarbons, tends to increase the fatty tissue of the body. This property is exhibited to a greater degree by glucose, which is more easily digested than cane-sugar. Sugar is extensively employed in pharmacy to disguise or improve the taste of medicines or to preserve them from decomposition.

Other Sugars.—GLUCOSE (see GLUCOSUM, p. 722).

LACTOSE (see SACCHARUM LACTIS, p. 1342).

LEVULOSE.—*Chylariose* or *Fruit-sugar.* $C_6H_{12}O_6$. Molecular weight, 178.74.—It frequently accompanies grape-sugar in fruits, also in honey; in some plants it is associated with cane-sugar. It is usually a colorless, uncrystallizable syrup, has nearly the same sweetness as cane-sugar, and is lævorotatory; its angle of rotation = −90.2°. It may be obtained in fine silky needles which are insoluble in absolute alcohol and ether, but dissolve readily in aqueous liquids. Levulose is produced from inulin by treatment with dilute acids; with nascent hydrogen it yields mannite. Among the products by oxidation with nitric acid are succinic, acetic, and oxalic acids.

INOSITE.—*Phaseo-mannite.* $C_6H_{12}O_6.2H_2O$. Molecular weight, 214.50.—It is present in the juice of some meats, in the green fruit of many leguminosæ, in asparagus, and in other plants. It is verp sweet, crystallizes readily from water and alcohol, is insoluble in ether, does not undergo alcoholic fermentation, and yields with nitric acid oxalic acid and explosive compounds.

INVERT SUGAR.—*Invertzucker*, G.; *Sucre inverti*, Fr. $(C_6H_{12}O_6)_2$. Molecular weight, 357.48.—Invert sugar occurs naturally in fruits, honey, and molasses. It is commercially prepared by inverting cane-sugar (sucrose) by means of *invertase* or dilute acids. It consists of equal parts of glucose (dextrose) and fructose (levulose). It is readily fermentable, the dextrose fermenting more readily than the levulose. It reduces Fehling's Solution and is lævogyre to polarized light. A solution which polarizes +100 before inversion will polarize −42.66° at 0° C. (32° F.), and will polarize 0° at a temperature of 90° C. (194° F.).

MALTOSE.—*Malt Sugar.* $C_{12}H_{22}O_{11}$. Molecular weight, 339.60.—Maltose is obtained by the action of diastase upon starch, or by boiling the latter with dilute mineral acids. It occurs in malt extract and certain varieties of commercial glucose. By continued action of the mineral acids it is convertible into dextrose. It is crystallizable in the form of thin needle-shaped crystals, $C_{12}H_{22}O_{11}.H_2O$. It is soluble in water and alcohol. It reduces Fehling's Solution. By heating with acids its reducing power is increased and its rotatory power decreased. It exhibits birotation, which is prevented by the addition of ammonia. Its normal specific rotatory power is $[a]_D = +139$. 10 Cc. Fehling's Solution = 0.0807 Gm. maltose.

RAFFINOSE.—*Melitriose. Pluszucker*, G. $C_{18}H_{32}O_{16}$. Molecular weight, 500.46.—Raffinose is contained in small quantity, about 0.02 per cent., in the sugar beet, and also in some varieties of manna, and in the cotton seed. It crystallizes in the form of thin needles, $C_{18}H_{32}O_{16} + 5H_2O$, which partly melt at 87° C. (188.6° F.) and become anhydrous at 110° C. (230° F.). The crystals are soluble in 7 parts of water at 20° C. (68° F.), in 10 parts of absolute methyl alcohol, in about 900 parts of 90 per cent. alcohol, and insoluble in absolute alcohol. It is dextrogyre; its angle of rotation = +104.5°. Like cane-sugar it does not reduce Fehling's Solution until it has been previously inverted. Boiling dilute acids invert it to dextrose, levulose, and galactose, thereby lowering its dextrorotatory power.

Classification of Sugars.—In composition and constitution sugars belong in part to the alcohols and in part to the aldehydes and ketones. To embrace the large number of synthetical sugars[1] the chemical nomenclature of the carbohydrates has been adapted to indicate the number of carbon atoms in the molecule by the prefixes *bi*, *tri*, *tetra*, *penta*, *hexa*, *hepta*, etc., and a molecular classification into Monoses and Polyoses—according to whether the molecule is simple or compound—*i. e.*, made up of a union of two or more of the simpler monoses. Accordingly the carbohydrates may be classified into:

[1] For a résumé of sugars see Lehrbuch der Organischen Chemie, by Victor Meyer and Jacobson, p. 876 *et seq.*, and the articles by Emil Fischer in Rer. *23*, p. 2114; *27*, p. 3189.

1. Monoses.

A. Saccharoids. Composition $C_nH_{2n+n}O_n$.—Nonfermentable. Alcohols in constitution, and yield the corresponding aldehyde on reduction.

(Triatomic alcohol) $C_3H_8O_3$, Glycerol. (Tetratomic alcohol) $C_4H_{10}O_4$, Erythritol. (Pentatomic alcohol) $C_5H_{12}O_5$, Arabitol, Xylitol. (Hexatomic alcohol) $C_6H_{14}O_6$, Dulcitol, Mannitol, Sorbitol.

B. Monosaccharides. Composition $C_nH_{2m}O_n$. Fermentable. Aldehydic in character, reduce Fehling's Solution, and yield characteristic *osazones* with phenylhydrazine.

Trioses. $C_3H_6O_3$. Glycerose. *Tetroses.* $C_4H_8O_4$. Erythrose.

Pentoses. $C_5H_{10}O_5$. Arabinose, Xylose, Ribose, Rhamnose (methyl-pentose).

Hexoses. $C_6H_{12}O_6$. This series is commonly termed glucoses. Formose, Fructose (Levulose), Galactose, Glucose (Dextrose), Mannose, Rhamno-hexose (methyl-hexose), Sorbose, Talose.

Heptoses. $C_7H_{14}O_7$. Gala-heptose, Gluco-heptose, Fructo-heptose, Manno-heptose, Rhamno-heptose.

Octoses. $C_8H_{16}O_8$. Manno-octose, Gluco-octose.

Nonoses. $C_9H_{18}O_9$. Manno-nonose, Gluco-nonose.

2. Polyoses. Polysaccharides. $(C_nH_{2n}O_n)_n$.

(*a*) Saccharoses. Compounds more or less readily hydrolized into simpler forms on heating with mineral acids, or by the action of enzymes.

C. Dioses. Disaccharides.

Dipentoses. $C_{10}H_{18}O_9$. Arabinon.

Di-hexoses. $C_{12}H_{22}O_{11}$. Sucrose (cane-sugar, maple sugar, refined beet sugar), Lactose (milk sugar), Maltose, Iso-maltose, Melebiose, Trehalose, Turanose.

D. Trihexoses. Trisaccharides. $C_{18}H_{32}O_{16}$. Raffinose, Melixetose.

(*b*) Compounds nonfermentable, but are hydrolized by continued *boiling* with mineral acids into the simpler form of glucose.

E. Polyoses. Polysaccharides. $(C_6H_{12}O_6)_n$.

Mostly amorphous compounds, including cellulose, dextrin, gums, glycogen, inulin, pectin, starch.

The *osazone* test for sugars is a very important one, as the resulting osazones are differentiated by crystalline form and melting-point. The test is performed as follows: To 1 part of the "sugar" add 2 parts of pure phenylhydrazine, 3 parts of sodium acetate (crystals), and 20 parts of water. The solution is then heated in boiling water for from 2 minutes to 1 hour. The following are the melting-points of some of the osazones from different sugars: arabinosazone 160° C., xylosazone 160° C., sorbinosazone 164° C., rhamnosazone, 180° C., galactosazone 193° C., glucosazone 205° C.

SACCHARUM LACTIS, *U. S.*, *Br.*, *P. G.*—Sugar of Milk.

Lactose, Milk-sugar, E.; *Sucre de lait, Lactine,* Fr.; *Milchzucker,* G.; *Azúcar de leche,* Sp.

A peculiar crystalline sugar obtained from the whey of cows' milk by evaporation and purified by recrystallization.

Formula $C_{12}H_{22}O_{11} + H_2O$. Molecular weight, 357.48.

Preparation.—Milk-sugar is one of the constituents of the milk of mammals, and appears to be present in larger proportion in the milk of herbivorous animals than in that of the carnivoræ. To obtain it the butter and casein are first removed, the whey is concentrated, and the liquid permitted to crystallize in large tanks, the crystallization being facilitated by the introduction of thin sticks or cords; the impure crystals are once or twice recrystallized from water. Prior to 1890 nearly all the milk-sugar used in America was produced in Switzerland, but since then large quantities are being made in this country, and at present the importation of Swiss milk-sugar has almost ceased. The present annual production of milk-sugar in the United States is estimated to amount to 1,500,000 pounds. Milk-sugar was manufactured as early as 1619, and was introduced into medicine by Testi in 1698.

Properties.—Sugar of milk occurs in commerce in white, hard, crystalline masses, or a white powder, feeling gritty on the tongue, odorless, and having a faintly sweet taste. It is permanent in the air. On incinerating a portion, the percentage of ash remaining should not exceed 0.25 per cent. Sugar of milk is soluble in 4.79 parts of water at 25° C. (77° F.) and in 1 part of boiling water, but is insoluble in absolute alcohol, ether, or chloroform. Its aqueous solution is neutral to litmus-paper, and is dextrogyrate. On adding to 5 Cc. of a hot, saturated, aqueous solution of sugar of milk an equal volume of sodium hydroxide test-solution and gently warming, the liquid

will turn yellow and finally brownish red. On the further addition of a few drops of cupric sulphate test-solution a brick-red precipitate will appear.—U. S. When heated to 130° C. (266° F.) milk-sugar parts with its water of crystallization without fusion, and leaves a white mass which again absorbs water, at a higher heat becomes yellow, and melts at 203.5° C. (398° F.) (Lieben); but above 170° C. (338° F.) it is converted into *lacto-caramel*, $C_6H_{10}O_5$, and afterward into products similar to those obtained on the dry distillation of cane-sugar and glucose. Milk-sugar does not readily undergo vinous fermentation until after it has been boiled with diluted sulphuric acid, which converts it into *galactose*, $C_6H_{12}O_6$, and glucose. In the presence of casein it is converted into *lactic acid*, alcohol being formed at the same time, but in small quantity only if the free acid is neutralized as fast as it is produced. By boiling with dilute nitric acid it is converted into mucic, saccharic, tartaric, racemic, and finally into oxalic, acid. Its hardness renders it serviceable for reducing other substances to a fine powder.

Citric acid in dilute solution does not alter milk-sugar on boiling (cane-sugar is inverted). In the reduction by Fehling's Solution 1 Cc. of Fehling's Solution is equivalent to 0.006786 Gm. of milk-sugar.

Tests.—If 1 Gm. of sugar of milk be sprinkled upon 5 Cc. of sulphuric acid contained in a flat-bottomed dish and covered with a watch-glass, the acid should acquire at most a greenish or reddish, but no brown or brownish-black color within half an hour (absence of cane-sugar). An aqueous solution of sugar of milk (1 in 10), mixed with a few drops of hydrochloric acid, and warmed to about 50° C. (122° F.), should not be colored or rendered turbid by the addition of an equal volume of freshly prepared hydrogen sulphide test-solution, after standing, well stoppered, in a warm place, 35° C. (95° F.), for at least ½ hour, nor should the further addition of ammonia-water to this solution cause a coloration or turbidity therein (absence of heavy metals). If 1 Gm. of powdered sugar of milk be boiled for 5 minutes with 50 Cc. of distilled water and the solution cooled, no blue coloration should be produced upon the addition of 1 drop of iodine test-solution (absence of starch).—U. S. It is important in applying the sulphuric acid test for the presence of cane-sugar that heat be avoided, as sugar of milk will char at an elevated temperature.

If 15 Gm. of pulverized milk-sugar be left in contact with 50 Cc. of dilute alcohol, and the mixture frequently agitated and filtered at the end of half an hour, 10 Cc. of the filtrate should give no turbidity when mixed with an equal volume of absolute alcohol, nor yield more than 0.04 Gm. of residue on evaporation (P. G.).

It should not leave more than 0.25 per cent. of ash on complete incineration. 1 Gm. dissolved in 10 Cc. of water gives a red color with solution of phenolphthalein after the addition of 3 drops of the volumetric solution of sodium hydroxide (limit of lactic acid) (Br.).

Action and Uses.—Sugar of milk is employed in medicine largely as a vehicle or diluent for other powders. It is not so sweet as cane-sugar, is less apt to irritate the stomach, and is considered to be more readily digested. In doses varying from 1 to 6 ounces (30–180 Gm.) in 24 hours it possesses distinct diuretic properties, and has been found of value in cardiac dropsy. It is the sweetening agent added to the formulas for modified milk given to bottle-fed infants, and when thus employed its diuretic property should be borne in mind.

SAFROLUM, *U. S.*—Safrol.

Safrol, Fr., G.

Formula, $C_{10}H_{10}O_2$ or $CH_2:CH.CH_2.C_6H_3\begin{matrix}O\\ \diagup\ \diagdown\\ O\end{matrix}CH_2$. Molecular weight, 160.86.

The methylene ether of allyl pyrocatechol, found in oil of sassafras, camphor oil, and other volatile oils, purified, if necessary, by repeated crystallization.—U. S. It is also found in the beans of Nectandra Puchury major and minor, in the barks of Athersperma Moschatum, Doryphora Sassafras, and Mespilodaphne Sassafras, and in the oil of various species of Cinnamomum.

Although safrol is the principal constituent of oil of sassafras, which contains as much as 80 per cent., it is commercially obtained from red oil of camphor by fractional distillation, by collecting the fraction boiling at about 230° C. (446° F.). The latter is further purified by repeated chilling and crystallizing.

Properties.—Safrol occurs as a colorless or faintly yellow liquid, with a sassafras-like odor. Its specific gravity is from 1.105 to 1.106 at 25° C. (77° F.), and its boiling-point lies at about 233° C. (451.4° F.). Safrol is optically inactive. On cooling to —20° C. (—4° F.) or below, it solidifies to a mass of crystals, which do not melt below 11° C. (51.8° F.). It is soluble in about an equal volume of strong alcohol, and in about 30 parts of 70 per cent. alcohol, and is miscible in all proportions with ether and chloroform.—U. S.

Safrol crystallizes in well-defined, colorless, monoclinic crystals, having the specific gravity of 1.108, melting at 12° C. (53.6° F.), and recongealing at —20° C. (—4° F.). It may be heated to 280° C. (536° F.) without decomposition. Heated with alcoholic potassium hydroxide solution, isosafrol is formed, which is less toxic than safrol. With bromine, safrol yields crystals of $C_{10}H_5Br_5O_2$.

Action and Uses.—Safrol is highly toxic in its action. It is employed in place of oil of sassafras, and reduces arterial pressure by depressing the vasomotor centre. When taken in small amounts for a protracted period it produces fatty degeneration of the heart, and particularly of the liver and kidneys. It is eliminated from the system principally as piperonalic acid.

SALEP.

Tubera Salep, P. G., *Radix salep.*—*Salep*, G., Fr., Sp.

The dried tubers of various species of *Orchis* and of allied plants (Fam. *Orchidaceæ*).

Origin.—Salep is collected in central and southern Europe and Asia, though the use of the oriental product has greatly declined. The varieties represent two forms, the one with branched, the other and preferable one with rounded and unbranched tubers. The tubers occur in pairs, one a little larger than the other. They are collected in autumn. When fresh, they are bitter. Partly to remove this bitterness and partly to make them dry more readily, they are immersed for a short time in boiling water, after collection.

Description.—Oriental salep is 25 to 40 Mm. (1–1⅗ In.) long, and usually dark-colored; European salep is always smaller. Salep is globular, pyriform, ovate, or oblong in shape, somewhat flattened or wrinkled, with a scar of the terminal bud at the apex, of a pale-brownish-yellow color, somewhat translucent, of a horny texture, hard, inodorous, and of an insipid, very mucilaginous taste. It is generally kept in the form of powder, which has a yellowish color. The tissue consists of thin-walled parenchyma filled with starch, the granules of which are more or less ruptured from scalding, and of large, nearly globular, cells containing gum. The scattered fibro-vascular bundles are small and thin, and a few cells contain raphides.

FIG. 356.

Salep: tubers and transverse section.

Branched salep tubers (*Radix palmæ Christi*) are somewhat flattened, and palmately 2- to 5-branched. The elongated mucilage-cells are not so large as in the other form.

Constituents.—The constituents of salep are subject to great variation in relative amounts, with the season of collection. Raspail found the old tuber, collected in autumn, to be free from starch, while the young one was richly supplied with it. The important constituents are starch and gum, with a little sugar and about 5 per cent. of proteid. The ash should be about 2 per cent.

Action and Uses.—Salep is nutritious and demulcent. Made into jelly, it is employed in some parts of Europe and Asia as an article of diet. To allay irritation of the gastro-intestinal canal it is used in mucilage made by shaking 1 part of powdered salep with 10 parts of cold water until it is uniformly diffused, when 90 parts of boiling water are added and the whole well agitated.

The oriental *Royal salep* is believed to have been derived from a plant related to the onion.

SALICINUM, *U. S.*, *Br.*—Salicin.

Orthohydroxybenzylglucoside.—*Salicine*, Fr.; *Salicin*, G.

A glucoside obtained from several species of salix and populus (Fam. *Salicaceæ*). Salicin should be kept in well-stoppered bottles.—U. S.

Formula, $C_{13}H_{18}O_7$ or $C_6H_{11}O_5.O.C_6H_4.CH_2OH$. Molecular weight, 283.99.

Origin.—Salicin exists in the bark of most species of salix and populus, and to a small extent also in the leaves and pistillate flowers. According to Herberger, it is best prepared from the bark of young wood, which contains it in relatively larger proportion than the trunk bark, and associated with smaller quantities of other compounds, which interfere with its isolation. It may also be prepared from populin by boiling it with lime-water or with solution of barium hydroxide. Salicin was discovered by Leroux (1830); in the same year Braconnot obtained from it saligenin and saliretin, without, however, recognizing their relations to salicin; these and the glucoside nature of the latter were first established by Piria (1838, 1845). The amount of salicin in the bark is very variable, and has been found to depend largely upon the species, sex of the tree, and the season, and also varies for different parts of the bark. David Brown (*Pharm. Jour.*, 1903, p. 588) found the following per cent. of salicin in the different parts of the bark of salicin purpurea: outer bark 2.5 per cent., middle bark 8 per cent., inner bark 11.3 per cent., whole bark 5.8 per cent. Salicin has also been obtained synthetically (Lesenko, 1864) from *helicin* by the action of sodium amalgam.

Preparation.—A decoction of willow-bark is deprived of tannin and coloring-matter by digesting it with levigated litharge (Duflos) or by precipitating with basic lead acetate (Peschier); in the latter case the free acid is afterward neutralized with calcium carbonate. The filtrate on concentration yields crystals which require purification by recrystallization. The tannin may also be removed by milk of lime, and the salicin taken up by alcohol from the filtrate concentrated to a soft extract.

Properties and Tests.—Salicin occurs in colorless, silky, shining, crystalline needles, rhombic prisms, or a white crystalline powder; odorless, and having a very bitter taste. Soluble in 21 parts of water and in 71 parts of alcohol at 25° C. (77° F.), in 3.3 parts of water at 80° C. (176° F.), and in 22 parts of alcohol at 60° C. (140° F.); insoluble in ether and chloroform. It melts at 201.4° C. (394.5° F.). Upon ignition, it is consumed, leaving no residue. Its aqueous solution is lævogyrate and neutral to litmus-paper. On heating a small portion of salicin in a test-tube until it turns brown, then adding a few Cc. of water, and afterward a drop of ferric chloride test-solution, a violet color will be produced. Sulphuric acid produces a red color, which disappears upon the addition of water. Upon gently heating 0.1 Gm. of salicin with 0.2 Gm. of potassium dichromate and 2 Cc. of diluted sulphuric acid, the odor of salicylic aldehyde will be developed. Sulphuric acid containing a trace of molybdic acid produces with salicin a violet color, changing to a deep brownish red. Sulphuric acid containing a trace of potassium iodate produces a dark red color, changing to deep purple. Sulphuric acid containing about one-fifth of its volume of solution of formaldehyde produces a deep purplish-red color. If to a small quantity of salicin a few drops of nitric acid be added, the liquid evaporated to dryness, and the resulting yellowish residue treated with ammonia-water and heated upon a water-bath with a fragment of potassium cyanide, a blood-red color will be developed. The aqueous solution of salicin is not precipitated by tannic or picric acid test-solution nor by mercuric potassium iodide test-solution (absence of, and difference from, alkaloids).—U. S.

Concentrated sulphuric acid dissolves salicin with a bright-red color; upon addition of a little water the liquid becomes colorless and deposits a red pulverulent substance, to which the name rutilin has been applied. When moderately warmed with diluted mineral acids salicin takes up water and splits up into dextrose and saligenin or salicylic alcohol, $C_7H_8O_2$, but if boiled with diluted acids the hydrolysis results in the formation of dextrose and saliretin, a yellowish-white, fusible, resinous body, $C_{14}H_{14}O_3$, insoluble in water, but readily soluble in alcohol, ether, and glacial acetic acid. Cold nitric acid of specific gravity 1.16 oxidizes salicin, with the production of *helicin*, $C_{13}H_{16}O_7$, which crystallizes in white needles, and is by ferments and dilute acids resolved into sugar and salicylic aldehyde. If nitric acid of specific gravity 1.09 is employed, salicin yields *helicoidin*, $C_{26}H_{34}O_{14}$, which may be regarded as a compound of salicin and helicin. These interesting reactions have been chiefly investigated by Piria (1837, etc.).

Action and Uses.—Salicin possesses antiseptic and antiferment properties similar to those of salicylic acid. Because of its bitter taste it may be employed as a stomachic to improve the appetite and promote digestion, and is of especial service if the impairment of these functions is partly due to decomposition of food in the stomach or intestine. After an extensive employment of salicin as a substitute for salicylic acid in the treatment of acute rheumatic fever, it is now regarded as inferior to the latter drug, but may be given if contraindications to the administration of salicylic acid exist. Although employed as an antiperiodic, it is much inferior to the cinchona alkaloids in malarial fever. It is largely used in cases of influenza. Salicin is given in the dose of 5 to 30 grains (0.30–2 Gm.) every 3 or 4 hours, usually dispensed in capsule or cachet.

Allied Glucoside.—SALINIGRIN.—Formula, $C_{13}H_{16}O_7$.—Discovered by H. A. D. Jowett (*Jour. Chem. Soc.*, 1900, Trans., p. 707) as the glucoside of Salix discolor. It forms needle-shaped anhydrous crystals, which melt without decomposition at 195° C. (383° F.) and solidify on cooling to a crystalline mass. It is soluble in about 52 parts of water and in 218 parts of alcohol, and is strongly lævorotatory; its angle of rotation = — 87.3°. It dissolves in concentrated sulphuric acid without producing a color (distinction from salicin).

SALIX.—Salix; Willow.

Weide, G.; *Saule*, Fr.; *Sauz* or *Sauce*, Sp.

The bark of various species of *Salix*, L. (Fam, *Salicaceæ*), principally that of *S. alba* L. (*White, European*, or *Duck willow*). The genus comprises more than 150 species of diœcious trees and shrubs, ranging through the north-temperate and Arctic regions, and a few extending into the southern hemisphere. They vary in size from large trees to creeping undershrubs, some not more than an inch or two in height. They are of great interest as contributing the most northern arborescent and shrubby vegetation, becoming thus of the greatest economic importance in Arctic regions. The young branches are usually very smooth, and, by their color, divide the genus into 2 sections, the twigs of the one inclining to red or purple, of the other to yellow. It is said that the latter contain the larger percentages of tannin, the former of salicin. These 2 constituents give to the barks their medicinal importance. The plants are of further economic importance because the wood yields a charcoal very pure as to its carbon, and useful for gunpowder manufacture. The young branches are the sources of osiers, of such great value in construction work.

FIG. 357.

Willow-bark: transverse section (× 15).

S. alba is a very common European species and has been largely naturalized in this country, where it grows, not very tall, but with a thick trunk and widely spreading crown, along streams and in other damp localities. The trunk-bark is blackish and rough-scaly, the twigs yellowish, shining, and attached in a frail manner to their branches, the latter character giving to this and some other species, mostly of the yellow barked class, the name of *Crack willows*. This name is sometimes applied distinctively to *S. fragilis* L., the species most used in the manufacture of salicin. The mature wood is soft and weak, although the twigs are tough. The stipules are deciduous and broadly lanceolate, the leaf-blades on short petioles and 2 to 4 or 5 inches long, one-third to two-thirds of an inch wide, narrowed toward the base, finely serrate, more or less silky-hairy, at least when young. The flowers are in yellow or greenish cylindrical catkins an inch or two long and about a quarter of an inch thick and appear with the young leaves in early spring. During the spring flow of sap the bark is very easily separated, and that is the time of collection.

Description.—Mostly in quills or irregular strips which are tough and flexible; bark 1 to 2 Mm. ($\frac{1}{25}$ to $\frac{1}{12}$ In.) thick, externally smooth or somewhat wrinkled, somewhat shining, yellowish brown to grayish brown and more or less warty, the warts small, roundish, mostly dark colored; inner surface long- and fine-striate, from pale brownish to cinnamon brown. Underneath the thin corky layer occurs a green layer. The bast-layer is transversely striated by very fine medullary rays, has a tangential structure and is readily separable into thin shreds; odor scarcely any; taste bitter and astringent.

An inferior form is sometimes collected from old wood, and deprived of its cork, when it has a dull, fibrous outer surface similar to the inner. This bark is less bitter than that which is younger. Willow-bark should not be kept on hand for a long time, since it undergoes a rapid loss of its salicin.

Constituents.—As stated above, the important constituents of Salix are salicin and tannin, which occur with gum, wax, fat, and sugar. Salicin (see SALICINUM) exists to the extent usually of between 1.5 and 2 per cent., though in some species it reaches 3 per cent. or even more. Tannic acid is present to the extent of about 10 per cent. This tannin is a glucoside, blue-black with ferric salts, then purplish-red on the addition of soda. The relative percentages of these constituents are believed to differ with the season of collection, but there is little definite information to be had on the subject. There is also a small amount of a third glucoside, *helicin* ($C_{13}H_{16}O_7 + \frac{3}{4}H_2O$), which is neutral, bitterish, has a melting-point of 175° C. (347° F.), is soluble in 64 parts of cold water and in alcohol, but not in ether, and is colored yellow by concentrated sulphuric acid.

Action and Uses.—Willow bark was formerly used as a stomachic and as an antiperiodic in the treatment of intermittents, but is to-day rarely prescribed in regular medicine. The dose of willow bark as a tonic is from 10 to 30 grains (0.60–2 Gm.) 3 times a day, in powder, infusion, or decoction. As an antiperiodic, 1 ounce (30 Gm.) should be given during the interval.

Other Varieties.—*Black willow bark* is considerably employed in this country, but has nothing to entitle it to preference. Its buds are also used and possess some slight aromatic properties in addition to those pertaining to the bark.

Salicaceæ.—The family contains only the two genera *Salix*, described above, and *Populus*, L., containing the Poplars, Cotton-woods, and Aspens. The latter are distinguished from the willows by the fringed scales subtending their flowers, those of the willows being entire. The poplars also produce numerous seeds upon each of the placentæ, the willows only a few. The constituents of Poplar bark are practically the same as those of Willow bark. Poplar bark contains also the glucoside *Populin* or *Benzoyl-salicin* ($C_{20}H_{22}O_8$), which crystallizes in white, sweetish and somewhat acid needles, and yields with dilute acids benzoic acid, then the same decomposition-products as those from salicin. Treated with nitric acid, populin yields *benzohelicin* ($C_{20}H_{20}O_8$). The leaves of these plants also contain populin. The Poplar bark commonly employed is that of *P. alba* L., the Old World *White* or *Silver poplar* or *popple*, *Great aspen*, or *Abele*, its bark often known as *White bark*. This species is naturalized to some extent, though very locally, in the United States. The bark of the common *European aspen* (*P. tremulus* L.) and that of the *American aspen*, *Quaking asp*, *Quiver leaf* or *Trembling poplar* (*P. tremuloides* Mx.) are also considerably employed, as is that of the *Black*, *English*, *Catfoot*, or *Willow poplar* (*P. nigra* L.). The buds of the last-named species are also used like willow buds.

From *P. balsamifera* is obtained, by incision, an oleoresin which is often miscalled "Tacamahac balsam," and which is very similar to that contained in the buds.

SALVIA, *U. S.*—Salvia; Sage; Picked Sage.

Folia Salviæ, P. G.; *Sauge officinale*, Fr. Cod.; *Garden sage*, *Meadow sage*, *Save*, E.; *Salbei*, G.; *Sauge*, Fr.; *Salvia*, It., Sp.; *Salva*, Port.

The dried leaves of *Salvia officinalis* L. (Fam. *Labiatæ*).

Origin.—Sage is a gray-pubescent suffruticose perennial, native of Europe and everywhere cultivated for medicinal purposes or as a condiment. The plant is 60 to 90 Cm. (2 to 3 Ft.) high, much-branched, the branches erect-spreading, woody only at the base, quadrangular; leaves as described below; flowers 3-cymose in the axils of leaves and bracts toward the end of the branches, forming a narrow thyrsoid spike; calyx narrowly campanulate, bilabiate, brownish, pubescent, its segments mucronate; corolla much longer, violet-blue, strongly bilabiate, with the mouth ringent, the tube short, the upper lip depressed, helmet-shaped, notched, the lower lip spreading, 3-lobed; stamens 2, the cells of each widely divergent, one sterile; style long, exserted, slenderly 2-cleft.

For use as a drug, the leaves only should be collected, by hand, and they should be carefully dried in the shade. For distillation, the entire plant is mowed down, and such a product, carelessly dried, is often substituted for the official article. This article is often distinguished commercially as "Italian baled Sage," though sage leaves also come in large bales.

Description.—Rather long- and stout-petioled, the blades 3 to 7 Cm. (about 1 to 3 In.) long and nearly half as broad, oblong or slightly broader below the middle, rounded or subcordate at the base, mostly blunt at the summit, crenulate, thickish, gray-green and densely hairy, especially underneath, very strongly veined, the veins finely reticulate, often pinkish or purplish, as is the petiole; aromatic in odor and taste, the latter also bitter and somewhat astringent.

FIG. 358.

Salvia officinalis L.

FIG. 359.

Sage-leaf: upper and lower surface.

Constituents.—The important constituent of Sage is its volatile oil (see OLEUM SALVIÆ), usually a little less than 1 per cent. from the fresh leaves but 2 to 3 times as much from a first-class dried article. There is also an unstudied bitter principle which, from its sensible properties and effects, appears to be similar to the amaroid marrubium of horehound. Although it has been claimed that these leaves contain no tannin, they not only give clear tannin reactions with ferric salts, but they are distinctly astringent, this property giving part of their value as used for gargling. They also contain resin and gum.

Action and Uses.—Sage was highly esteemed by the ancients as a remedy in many different affections, as chronic pulmonary complaints, uterine derangements, excessive sweating, sore throat, etc. It possesses aromatic, astringent, and tonic properties in a mild degree, and though rarely employed as a modern scientific therapeutic agent, it is used by the laity as a remedy in dyspepsia, and as a diaphoretic given in infusion in the early stages of some febrile diseases. The dose of powdered sage is from 20 to 30 grains (1.3–2 Gm.), of the infusion 1 to 2 ounces (30–60 Cc.).

Other Salvias.—The genus *Salvia*, L., comprises some 500 species. Like most Labiate plants, they contain, generally, aromatic properties similar to those of the above, and *S. pratensis* L. and *S. Sclarea* L. have been official in some pharmacopœias, though generally regarded as inferior.

The name "Sage," with various prefixes, is popularly applied upon our western plains to many plants not at all related to Salvia, nor to one another, many of them being nutritious and important products, and some popular local medicines.

Chia is a Mexican name applied to the seed-like fruits of a number of species of Salvia. They are considerably used as foods, or for adding, in a powdered condition, to the poor water of alkaline regions to render it more palatable. The large amount of mucilage contained probably carries down part of the suspended impurities. They contain enough sugar to render them distinctly sweetish. In Persia, the seeds of *Lallemantia Royleana* Benth. are similarly used under the name *Tukmi-balung*.

Phlomis fruticosa L., a related plant, is used in Europe as a vulnerary, similarly to Salvia.

SAMBUCUS.—Sambucus; Elder Flowers.

Sambuci flores, Br.; *Flores Sambuci*, P. G.—*Sweet elder, Black elderberry*, E.; *Flieder, Hollunder*, G.; *Sureau*, Fr.; *Sahuco* or *Sauco*, Sp.; *Sambuco*, It.; *Sabugueiro*, Port.

The dried flowers of *Sambucus Canadensis* L. (Fam. *Caprifoliaceæ*).

The British and German pharmacopœias specify the flowers of *S. nigra* L., the common European Black Elderberry; the Portuguese names *S. vulgaris* Lam. (the author should be Neck.), which is a synonym for *S. nigra*.

Origin.—The plant yielding this drug is widely distributed throughout North America. It is a shrub some 2 or 3 M. (6 to 10 Ft.) high, the stems stout, simple or sparingly branched. It propagates by long root-like rhizomes and forms large clumps, chiefly along streams and in other moist places, especially in the edges of woods and thickets. The bark is light gray and smoothish and the wood-zone thin, enclosing a pith which usually occupies about three-fourths of the stem-diameter. This pith is considerably used for holding small objects for sectioning for microscopical purposes. The leaves are opposite, large, pinnate, the leaflets 7 to 11, short-stalked, lance-oblong, pointed, serrate. The creamy white, fragrant flowers are in very large flat-topped compound cymes and are succeeded by similar (but usually drooping) bunches of purplish black, shining, juicy, sweet and acidulous fruits, largely used for wine-making and somewhat for pie-making, preserving, etc. The flowers should be gathered as soon as fully opened and rapidly and carefully dried.

FIG. 360.

Elder: branch (½ Nat.); flower (× 3); fruit (× 5).

Description.—A yellowish or pale-brownish mass, consisting of shrivelled flowers free from stems, which, when expanded after soaking are about 5 Mm. (⅕ In.) broad; calyx-teeth 5, superior, minute; corolla rotate, deeply 5-lobed, the 5 stamens borne upon its throat, alternating with its lobes; odor mild, peculiar; taste mucilaginous, somewhat aromatic and bitterish.

When the microscope does not reveal tufts of short hairs in the sinuses of the calyx, the drug is not of this species.

Most pharmacopœias specify that dark-brown or blackish flowers should be rejected. This appearance may be due to their having been collected some time after opening, to carelessness in drying, or to having been preserved too long.

Constituents.—The constituents of the American drug do not appear to have been studied, but there is no reason to doubt their practical identity with those of the European. The latter contains less than half of 1 per cent. of a volatile oil, though the yield is apparently greater, owing to the water which comes over with it. This oil is the important constituent. It is best obtained by saturating the aqueous distillate with salt and removing the oil by means of ether. This oil is a yellow or greenish-yellow butter-like mass, melting when warmed. It possesses a very powerful odor and a bitter, warming and afterward cooling taste. Its composition has been little investigated. With it exist considerable gum, a little acrid resin, a little tannin, and calcium and potassium malates.

Action and Uses.—Elder flowers are almost devoid of active medicinal virtue, and are rarely employed, except as a household remedy. When in infusion, ointment, or poultice, they are applied to sores, blisters, hemorrhoids, etc.

Other Products.—Fresh Elderberries have been found to possess sudorific properties similar to those of the flowers, but weaker. The coloring-matter extracted from them has been considerably used as an indicator for alkalies, with which it gives a green color, being red with acids. According to Cowie, this coloring-matter is best extracted, in the form of a 20 per cent. tincture, from the refuse remaining after the expression of the fresh juice.

All the other parts of the Elderberry plant, excepting the wood and pith, are more active than either the flowers or the fruit. The inner bark of the stem of both the foreign and the American species has been much employed as a diuretic, and has been found to contain small amounts of volatile oil and valerianic acid, together with resin, sugar, and fixed oil. Statements differ as to the presence of tannin. Starch is wanting. The young shoots and leaves of *S. nigra* not only share the diuretic and, in larger doses, purgative properties of the inner bark, but they have also been found valuable as an insecticide, and especially for keeping away flies and other insects, which apparently find the odor highly objectionable. The juice of the root has been known from ancient times as a nauseant, in moderate doses producing both vomiting and purging. The fresh root of *S. Canadensis* has been found extremely poisonous, producing death in children within a short time after being eaten, and with symptoms very similar indeed to those of poisoning by Cicuta. De Sanctis claims to have isolated the alkaloid coniine from the branches and leaves of *S. nigra*. Alpers (*Proc. Amer. Pharm. Assoc.*, 1900, p. 190) found undoubted evidences of an alkaloid in the roots of *S. Canadensis*, its odor being somewhat similar to that of coniine and also suggesting nicotine. This alkaloid was evidently volatile. It appeared to be much less abundant in the dried roots after some months' keeping.

The genus *Sambucus* L., contains about 20 species, and there are indications that many of them share in the properties described above.

SANDARACA.—Sandarac.

Sandaraca or Sandarac (*Juniper resin*, E.; *Sandarak*, G.; *Sandaraque*, Fr.) is the product of several species of *Callitris*, small trees or large shrubs, especially of *C. quadrivalvis* Vent. (*Thuja articulata* Vahl.), which grow in northwestern Africa. The oleoresin exudes from natural openings, and incisions are also made for it. The tears are mostly less than an inch in length, of a stalactite form, mostly slender and angular, often compound. They are pale yellow, mostly dusty, and have a sharp glassy fracture, clear in the centre, pulverulent at the edge. Sandarac has a terebinthinate odor, slight except after warming. It is pulverulent and not at all plastic on being chewed, and there is a slight bitter with the sharply terebinthinate taste. It melts at 135° C., has an acid number of 136 to 140, and is soluble in ether, acetone, and alcohol, but only partly in chloroform, carbon disulphide, and essential oils.

Substitutes.—Several spurious sandaracs have appeared upon the market, the most important being that of Australia and Tasmania, produced by the *Actinostrobus acuminata* Parl., as well as by a number of species of *Callitris*. It agrees so closely with the African in all respects that it seems almost improper to speak of it as a substitute at all. A much more serious matter is the sale (see Haneki, *Pharm. Jour.*, No. 1596, p. 79) of a fictitious Spanish article, apparently manufactured from ordinary rosin. It was described as in terete tears and becoming somewhat plastic on chewing, melted on the water-bath, had an acid number of 168, and had very much the solvency of rosin.

Constituents.—Besides a very small amount of an unknown bitter principle, Sandarac consists essentially of several resins, 3 according to Unverdorben. Tschirch reports it as consisting principally of 85 per cent. of *Sandaracolic acid* ($C_{45}H_{84}O_8$) and 10 per cent. of *Callitrolic acid* ($C_{65}H_{54}O_8$). The amount of volatile oil which can be separated depends entirely upon the freshness of the sample, since it evaporates very rapidly after collection. It consists chiefly of a diterpene, boiling at 265° C. (509° F.).

Action and Uses.—Sandarac is used chiefly as an ingredient in rapidly drying varnishes. It has been given internally in chronic affections of the bronchial and urinary mucous membranes, and used as an ingredient of many stimulating ointments.

SANGUINARIA, *U. S.*—Sanguinaria.

Bloodroot, Red puccoon, Tetterwort, Red Indian paint, E.; *Blutwurzel*, G.; *Sanguinaire*, Fr.

The dried rhizome of *Sanguinaria Canadensis* L. (Fam. *Papaveraceæ*), collected after the death of the foliage.

Sanguinaria is official in no other pharmacopœia.

Origin.—The bloodroot plant is a native of eastern and central North America, occurring in greatest abundance on rocky, partly shaded banks, in rich soil. It is one of the earliest and most pleasing of wild flowers, producing its pure white flowers before the development of its leaves, which afterward enlarge greatly. The plant is smooth and the leaves are of a pale glaucous green. By midsummer the fruit is matured and the foliage is dead, after which the aërial portions of the plant quickly disappear. All parts of the plant exude a red juice. The form of the Gulf region presents quite marked distinctions from that of the North, and may yet be found specifically distinct.

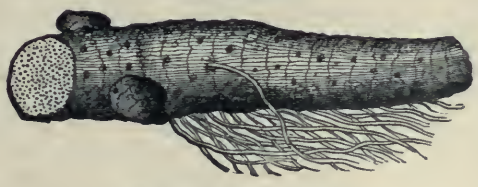
Fig. 361.

Bloodroot (plant, ½ Nat.; dried rhizome, Nat.).

Description.—From 2 to 7 Cm. (about 1 to 3 In.) long and 0.5 to 1 Cm. ($\frac{1}{5}$ to $\frac{2}{5}$ In.) thick, often with several short branches, oblong to cylindrical, straight or crooked, inconspicuously and incompletely annulate, finely wrinkled externally, of a rich- or reddish-brown; fracture short and sharp, the rather thin bark red-brown, the remainder whitish or yellowish, marked with numerous small red resin-dots, or of a nearly uniform orange-red to brownish-red color; odor slight, the powder sternutatory; taste persistently bitter and acrid.

The red powder exhibits numerous large bright-red resin-cells, parenchyma filled with starch, the grains mostly single, of roundish form, and mostly 10 to 15 microns in diameter. Bloodroot is occasionally contaminated with other substances, but we have never seen it actually adulterated, and its cross-section is distinct from that of everything which otherwise at all resembles it.

Fig. 362.



Bloodroot, fresh rhizome.

Constituents.—The important constituents of Sanguinaria are its alkaloids, of which at least 5 are present, namely, sanguinarine, chelerythrine, fumarine (protopine), and β- and γ-homochelidonine. Most of these alkaloids have been considered elsewhere in this work. *Sanguinarine* ($C_{20}H_{15}NO_4 + H_2O$) is generally regarded as the most important constituent from a medicinal point of view, though chelerythrine is many times more abundant. The former occurs in colorless crystals and yields brilliant red salts, by which character alone it can be readily recognized. It is exceedingly difficult of separation in a pure state, and comparatively little is known of it. Schlotterbeck reports that the sanguinarine nitrate of the market is not a pure article, but consists chiefly of chelerythrine instead. With the alkaloids occur citric and malic acids, red resin, much starch and unimportant constituents.

Pharmaceutical Preparations.—Fluidextract of Sanguinaria, Tincture of Sanguinaria, U. S. P.

Action and Uses.—In small doses sanguinaria produces a sense of warmth in the stomach and stimulates gastric secretion. Moderate doses produce nausea and circulatory depression, and in large doses it inflames the stomach, causing intense burning, thirst, vomiting, dimness of vision, vertigo, great prostration, and collapse. Powdered sanguinaria snuffed up the nostrils is sternutatory, and applied locally it acts as a stimulant to indolent ulcers and as an escharotic to fungous granulations. The physiological

action of sanguinaria bears no relation to its principal therapeutic application, namely, as a stimulating expectorant in subacute and chronic bronchitis. It was formerly employed to stimulate duodenal secretion in catarrh of the duodenum and secondary catarrh of the bile ducts, as an emmenagogue in atonic and functional amenorrhœa, as an alterative in chronic syphilis, and as an aphrodisiac, but for these purposes it is at present rarely administered. The expectorant dose of sanguinaria is from 1 to 5 grains (0.06–0.30 Gm.), and of the tincture, in which it is preferably administered, from 10 to 40 minims (0.60–2.60 Cc.). As an emetic the crude drug may be given in the dose of from 10 to 40 grains (0.60–2.60 Gm.). The physiological action of sanguinarine is practically identical with the crude drug. Its dose as an expectorant is from $\frac{1}{12}$ to $\frac{1}{8}$ grain (0.005–0.008 Gm.), as an emetic from $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.015–0.03 Gm.).

SANTALUM RUBRUM, *U. S.*—Red Saunders.

Pterocarpi lignum, Br.; *Lignum santalinum rubrum, Rasura ligni.—Red santal* or *sandal-wood, Ruby-wood*, E.; *Rothes Sandelholz*, G.; *Santal rouge*, Fr.; *Sandalo rojo*, Sp.; *Sandalo rubro*, Port.

The heart-wood of *Pterocarpus santalinus* L. f. (*Lingoum s.*—Kuntze—Fam. *Leguminosæ*).

Red Saunders is official in most pharmacopœias, though a number specify the wood of *P. Indicus* Willd. (*P. Draco* Lam.).

Origin and Description.—This is a small tree, native and cultivated in the East Indies. The wood is commonly imported in billets, but is usually supplied to the pharmacist in the form of a coarsely rasped powder, sometimes as chips or splinters. It is hard and very heavy, splitting easily in a straight line, and varies in color from a deep, slightly purplish-red when fresh to a blood-red or brownish-red after exposure. The ducts are relatively large. It is nearly odorless and tasteless, does not tinge the saliva nor yield its color to water, while alcohol is colored by it deep-red, then dark-violet on the addition of ferric chloride.

Constituents.—Although Red Saunders contains several crystallizable principles (*pterocarpin*, a little tannin, etc.), it is valued solely for its red coloring-matter, *santalic acid* or *santalin* ($C_{15}H_{14}O_5$). This occurs in fine red, odorless, and tasteless needles, melting at 104° C. (219.2° F.), insoluble in water, soluble in alcohol with a blood-red color, in ether yellow, in concentrated sulphuric acid deep red, and in alkalies violet. It is also soluble in the volatile oils of cloves, cinnamon, bergamot, and bitter almond, but insoluble in most other volatile and fixed oils. The amount of santalic acid present in the wood ranges apparently from 0.25 to 0.5 per cent.

Action and Uses.—Red Saunders is used only as a coloring-agent. It has no medicinal virtues.

A very similar article, closely related and probably containing the same coloring-matter, is the African *Cam-wood*, derived from *Baphia nitida* DC., of the same family. *P. erinaceus* Poir., also of Africa, yields a kind of rose-wood, and the sap is converted into *African Kino*. *P. Draco* L. (not Lam.) yields *West Indian dragon's-blood*.

SANTONICA, *U. S.*—Santonica.

Flores Cinæ, P. G.; *Flores artemisiæ, Semen cinæ, Santonici, contra* or *sanctum.—Levant, Turkestan, Aleppo*, or *Alexandria wormseed*, E.; *Wurmsamen, Zittwersamen, Cinablüthen*, G.; *Semen-contra, Semencine, Barbotine*, Fr.; *Semen santo, Flore di Cina*, It.; *Simiente de Alejandria, Yantonica*, Sp.; *Barbotina*, Port.

The dried unexpanded flower-heads of *Artemisia pauciflora* (Ledeb.) Weber (*A. maritima pauciflora* Ledeb.; *A. maritima Stechmanniana* Besser; *A. Lercheana* Kar. et Kir.—Fam. *Compositæ*).

Santonica is official in most pharmacopœias, though the titles named above are variously employed. Most of them refer the drug to *Artemisia Cina* Berg. The Belgian refers it to *A. Contra* L.

Origin.—The plant is a low and scraggly undershrub, with erect branches, abounding in the deserts of Turkestan, where the whole of the drug is collected, in July and August, by native tribes. It pertains to a perplexing group of species of this difficult

genus, variously regarded by different botanists as distinct species or as varieties of the polymorphous species, *A. maritima* L., of the Mediterranean basin and northeastward.

Description.—A yellowish green (at length greenish brown), somewhat glossy, mobile mass; having a strong and peculiar, somewhat camphoraceous odor and an aromatic and bitter taste; heads 2 to 4 Mm. ($\frac{1}{12}$ to $\frac{1}{6}$ In.) long, oblong-ovoid, slightly flattened, obtuse, consisting of an involucre of about 12 to 18 closely imbricated, glandular scales with broad midribs, enclosing 4 or 5 rudimentary florets.

Fig. 363.

Santonica: head and longitudinal section (× 10).

Santonica should be carefully protected against exposure to light and atmosphere, and not kept too long, since its active constituent becomes transformed. This change is commonly indicated by an increase in the brown coloration. The greater part of the crop is manufactured into santonin in its own home, and the exportation of the inferior lots of santonica appears too common.

Constituents.—The only constituents of note in Santonica are its 2 or 3 per cent. of volatile oil, santonin (see Santoninum), and artemisin. Oil of Santonica is a commercial article. It is yellowish-white, clear, having the odor of Santonica, though more camphoraceous, and a specific gravity of from 0.915 to 0.940. It consists chiefly of cineol and possesses the properties of that substance. Artemisin is a crystalline body, apparently oxysantonin, and exists in variable amount. Of santonin there should be from 2.5 to 3.5 per cent., yet the commercial article rarely yields more than 2 per cent., often less.

Action and Uses.—Since the isolation of santonin from santonica, the use of the crude drug has been practically abandoned. It may be used as a vermicide for round worms, when it is administered either in infusion or in an electuary in combination with molasses or honey. Its dose is from 10 to 40 grains (0.60–2.60 Gm.).

Allied Drugs. (See also Chenopodium.)—*Barbary wormseed* is a somewhat similar product, apparently derived from a closely related species of northwestern Africa. The heads are shorter, more rounded, and somewhat gray-downy. *East Indian wormseed* is much smaller and is hairy.

SANTONINUM, *U. S., Br., P. G.*—Santonin.

Santonine, Fr. Cod.; *Santonina, Santonine, Anhydride santonique*, Fr.; *Santonin*, G.; *Santonina*, Sp.

Formula, $C_{15}H_{18}O_3$. Molecular weight, 244.29.

The inner anhydride or lactone of santonic acid, obtained from Santonica.—U. S. A crystalline principle prepared from the dried unexpanded flower-heads or capitula of Artimisia maritima, var. Stechmanniana, Besser.—Br.

Santonin was discovered in 1830 simultaneously by two German apothecaries, Kahler and Alms, and later investigated by Tromsdorff, Liebig, and others.

Preparation.—Santonin is obtained by mixing 5 parts of crushed santonica with 1 part of slaked lime and then exhausting the mixture repeatedly with hot water, or the mixture may be boiled for some time with water and then strained. In either case a solution of calcium santoninate is obtained, which is concentrated by evaporation to a syrupy consistence, and then decomposed with hydrochloric acid. Crude santonin is precipitated but contaminated with resinous matter, from which it may be freed by washing with dilute ammonia-water, or by recrystallization from hot alcohol, a little charcoal being used to remove coloring-matter, the resin remaining dissolved in the alcohol. The yield may vary from 1½ to 3 per cent., some loss occurring in the process. Santonin is now produced cheaply and in large quantities at Tschimkent in Turkestan.

Properties and Tests.—Santonin occurs in colorless, shining, flattened, rhombic prisms; odorless and nearly tasteless when first put into the mouth, but afterward developing a bitter taste; permanent in the air, but turning yellow on exposure to light. It sublimes without decomposition, and is soluble in alkalies and in most volatile and fatty oils. Santonin which has become yellow may be converted into white crystals by recrystallization from alcohol. Soluble in 5300 parts of water, 34 parts of alcohol, 78

parts of ether, and in 2.5 parts of chloroform at 25° C. (77° F.); soluble in 800 parts of water at 80° C. (176° F.), and in 5 parts of alcohol at 60° C. (140° F.). It melts at 170.3° C. (338.5° F.). When ignited it is consumed, leaving no residue. Its solutions are lævogyrate and neutral to litmus-paper. If 0.5 Gm. of santonin be heated with 5 Cc. of alcoholic potassium hydroxide test-solution, a red color will be developed. Upon shaking 0.01 Gm. of santonin with a cold mixture of 1 Cc. each of sulphuric acid and water, heating to 100° C. (212° F.), and adding a minute trace of very dilute solution of ferric chloride, a violet color will result. Sulphuric acid added to santonin should not produce more than a faintly yellow color (absence of sugar and other readily carbonizable organic impurities). If 2 Gm. of santonin be boiled with 80 Cc. of water and 5 Cc. of diluted sulphuric acid, and the liquid, after frequent shaking, be allowed to become cold and then filtered, mercuric potassium iodide test-solution or iodine test-solution should produce no cloudiness in 10 Cc. of the filtrate, mixed with 10 Cc. of distilled water, even after standing for 3 hours (absence of alkaloids).—U. S. The above-mentioned reaction of santonin with potassium hydroxide is not entirely satisfactory, and can be improved by following the suggestion of Percy Paine (*Brit. Pharm. Conf. Trans.*, 1901), to dissolve a few crystals of santonin in 2 or 3 Cc. of alcoholic solution of ethyl nitrite and then add a few drops of alcoholic solution of potassium hydroxide, when a beautiful rose-red color will appear. Aloin and resorcin will develop a rose-red color before addition of the alkali, but santonin not until after the addition has been made. The Ph. G. gives the solubility of santonin at 15° C. (59° F.) as 1 part in 5000 parts of water, or 44 parts of alcohol, or 4 parts of chloroform. The same authority gives the following test for possible presence of strychnine: If 1 part of santonin be boiled with 100 parts of water and 5 parts of diluted sulphuric acid, the mixture allowed to become cold and then filtered, the filtrate should not possess a bitter taste nor be precipitated upon addition of a few drops of potassium dichromate solution.

Santonin has been found adulterated with boric acid, which latter may be recognized by its insolubility in chloroform and its non-volatility. If boric acid be present, the residue left upon heating the suspected santonin on platinum foil, if dissolved in water and acidulated with hydrochloric acid, will color yellow turmeric-paper brown. There is little or no danger of confounding santonin turned yellow from exposure to light with picric acid, as the latter readily forms yellow-colored solutions with cold and hot water.

If santonin be melted it yields a colorless liquid, which, if slowly cooled, becomes crystalline, but if rapidly cooled, remains amorphous and gum-like, the latter becoming again crystalline on warming to a little over 40° C. (104° F.) or on moistening with alcohol or ether. If carefully heated, santonin may be sublimed in the form of needle-shaped crystals.

If a solution of santonin in sulphuric acid be heated on the water-bath for several hours and then diluted with water, an isomeric body, isosantonin, having the melting-point 138° C. (280.4° F.), will be precipitated. Santonin is transiently colored red by hot alkalies and alkaline earths, the colorless solutions containing the alkali salts of santoninic acid, and yielding precipitates of santoninates with most of the salts of the metals. At 120° C. (248° F.) santoninic acid, $C_{15}H_{20}O_4$, is decomposed into santonin and water. On boiling santonin with a solution of barium hydroxide for 12 hours, an isomer of santoninic acid, santonic acid, melting at 161° to 163° C. (321.8°–325.4° F.), is obtained.

If a 7 per cent. solution of santonin in 80 per cent. acetic acid be exposed to the action of sunlight for 30 days or more, bibasic photosantonic acid, $C_{15}H_{22}O_5$, will be formed, which may be obtained in prismatic crystals melting at 153° C. (307.4° F.) and slightly soluble in water, but readily so in alcohol, ether, and chloroform. By exposing a 2 per cent. alcoholic solution of santonin in a similar manner, photosantonin, $C_{15}H_{19}(C_2H_5)O_4$, the ethyl ether of the above-named acid, is produced.

Pharmaceutical Preparation.—Santonin Lozenges, U. S. P.

Action and Uses.—Santonin is sometimes employed to restore the acuity of vision when it is impaired by disease of the optic nerve. In persistent incontinence of urine it may produce a cure after all other remedies have failed. Its most important use is as an anthelmintic for the removal from the intestine of the Ascaris lumbricoides, or round worm. It has little or no effect upon the tapeworm. Toxic doses produce alarming symptoms, the most constant of which are muscular tremors, vertigo, cold sweats, mydriasis, stupor, and epileptiform convulsions. A remarkable and not uncommon effect of

santonin, even in medicinal doses, is the production of xanthopsia, a condition in which objects appear as if viewed through a yellow glass, although other colors, as red, green, or blue, may appear. This effect is thought by some observers to be due to the staining of the humors of the eye by the drug; by others, to its action upon the retina and perceptive centres in the brain. To the urine santonin imparts usually a deep-yellow color, and if the dose be large or the urine alkaline in reaction, it may be stained red or purple. As an anthelmintic, santonin should be administered on a fasting stomach. In from 4 to 6 hours after its administration a dose of calomel should be given, and this followed in 2 hours by a saline. Santonin is given preferably in crystals, which are more slowly dissolved and absorbed than the powder. Although it is almost tasteless, it is usually combined with sugar or powdered chocolate, or made into troches. The official troche contains ½ grain (0.03 Gm.) of santonin. The dose to an adult is from 1 to 2 grains (0.06–0.12 Gm.); the usual dose to a child is from ¼ to ½ grain (0.015–0.03 Gm.).

Derivative Compounds. SANTONINOXIME. $C_{15}H_{18}O_2.NOH$. It is prepared by heating for about 7 hours a mixture of 5 parts of santonin, 4 parts of hydroxylamine hydrochloride, 50 parts of alcohol, and 4 parts of calcium carbonate. After filtration of the mixture, santoninoxime is precipitated from the alcoholic liquid by addition of water. It occurs as colorless needle-shaped crystals, which are insoluble in water, but quite soluble in alcohol, oils, and fats. It melts at 216° to 217° C. (420.8°–422.6° F.). Santoninoxime is used medicinally for the same purpose as santonin, and is said to be far less toxic than the latter.

Sodium Santoninate. $C_{15}H_{19}NaO_4 + 3\frac{1}{2}H_2O$. This salt, which was at one time (1880) recognized in the U. S. Pharmacopœia, may be obtained by heating a mixture of 10 parts of santonin, 40 parts of water, and 9.5 parts of 15 per cent. sodium hydroxide solution on a water-bath until solution is effected. The liquid is then concentrated and allowed to crystallize. Sodium santoninate occurs as colorless, transparent, tabular crystals, having a bitter and mildly saline taste. It is soluble in 3 parts of cold water and in 13 parts of alcohol. Sodium santoninate and other santoninates should not be employed. They are more soluble than santonin and more readily absorbed from the stomach, properties undesirable in vermicides which are to act locally in the intestine.

SAPO, *U. S.*—Soap.

Sapo durus, Br.; *Savon médicinal,* Fr. Cod.; *Sapo medicatus,* P. G. *Sapo hispanicus.—Hard soap, Castile soap,* E.; *Savon médicinal, Savon amygdalin,* Fr.; *Medizinische Seife, Spanische Seife, Oelseife,* G.

Soap prepared from sodium hydroxide and olive oil.—U. S. Soap made with sodium hydroxide and olive oil; containing about 30 per cent. of water.—Br.

Although the name Soap is officially restricted to the compound designated above, it is in general use for all compounds of fatty acids with alkaline bases, which are soluble in water and alcohol, and the process involved in the manufacture of such compounds is known as saponification. The compounds of fatty acids with earthy and metallic bases, while chemically analogous to soluble soaps, are usually designated as plasters or insoluble soaps, such as lead plaster and lime liniment.

The general plan of saponification consists in boiling fats or fixed oils with a solution of sodium or potassium hydroxide, or with metallic oxides in the presence of water, and involves the decomposition of the fat by the base, new fatty acid salts being formed and glycerin being liberated. In the case of the alkali hydroxides, the newly formed soap enters into solution in the water together with the glycerin, and is subsequently recovered. The lye used in this operation is employed in a rather dilute state, is gradually added, and an excess of it mostly used, since saponification is thereby much facilitated, and the free alkali may be removed from the soap. The decomposition of fats and fixed oils progresses gradually, the triolein, tripalmitin, or tristearin being first converted into the di- and mono-acid compounds of glyceryl before saponification is completed, and hence the mixture must be kept boiling until it becomes transparent and rather tenacious. The soap is finally separated from the lye by adding a solution of common salt to the liquid, soap being insoluble in the solutions of most salts of potassium and sodium. When the soap has separated from the liquor and sufficiently solidified, it is transferred to wooden trays until it is stiff enough to be cut into pieces, which are exposed to the air in a warm place until they become hard and dry.

Neither the U. S. nor Br. Pharmacopœia gives an official process for the manufacture of soap. The Ph. G. directs that a mixture of 50 parts each of lard and olive oil, previously melted together, be heated for ½ hour, constantly stirring, with 120 parts of a 15 per cent. sodium hydroxide solution, after which 12 parts of alcohol are added, and finally 200 parts of water together with small quantities of the above sodium hydroxide solution, if necessary, until a uniform transparent soap results, perfectly soluble in hot water. Finally, a filtered solution of 25 parts of sodium chloride and 3 parts of sodium hydroxide in 80 parts of water is added, and the mixture heated until the soap is precipitated. After removal of the soap it is washed with small portions of water, strongly expressed, and dried.

The French Codex orders the official soap to be made from oil of sweet almond by mixing it with ½ its weight of soapmaker's lye (29 per cent. solution of sodium hydroxide), and keeping the mixture in a moderately warm place, with occasional stirring, until it solidifies.

Properties.—Soap is a white or whitish solid, hard, yet easily cut when fresh, having a faint, peculiar odor free from rancidity, a disagreeable, alkaline taste, and an alkaline reaction. It is soluble in water and in alcohol, more readily with the aid of heat (soluble in 20 parts of cold or 1½ parts of hot water, and in 90 per cent. alcohol, Br.).—U. S.

The consistence of soap depends mainly on the particular alkali employed, but also in part on the nature of the fat used. Soda soaps are invariably harder than potash soaps, and drying oils yield softer soaps than non-drying oils; fats rich in palmitic or stearic acid yield firmer and less soluble soaps than fixed oils consisting chiefly of olein. Potash soaps are mostly deliquescent; dry potassium palmitate readily absorbs from the air about ½ its weight of moisture, and potassium oleate about 1½ times its weight, whereas the corresponding sodium compounds absorb only 8 and 12 per cent. respectively.

The well-known detergent properties of soap depend upon its decomposition by a large quantity of water into acid and basic salts, of which the latter contain about 50 per cent. more alkali than the former, and act as solvents of fats and other matters; in this respect their action is similar to, but milder than, that of caustic alkali. Alcohol does not have this dissociating effect on soap. So-called hard water is unsuited for washing on account of calcium or magnesium salts which are contained in solution, and which form insoluble soaps by double decomposition.

Tests.—On placing 0.5 Gm. of soap, together with about 10 Cc. of alcohol, in a tared beaker containing 1 Gm. of dry clean sand, evaporating the resulting solution of the soap to dryness, and drying the residue at 110° C. (230° F.) to a constant weight, the loss should not exceed 36 per cent. (absence of an undue amount of water). An alcoholic solution of soap (1 in 25) should not gelatinize on cooling (absence of animal fats). An aqueous solution of soap (1 in 20) should remain unchanged in color upon the addition of ammonium sulphide test-solution, and upon acidulating another portion of the solution with hydrochloric acid and filtering, the filtrate should remain unchanged in color when an equal volume of hydrogen sulphide test-solution is added and the mixture is allowed to stand well-stoppered in a warm place for ½ hour (absence of metallic impurities). On dissolving 20 Gm. of soap in alcohol, with the aid of heat, transferring the undissolved residue, if any, to a tared filter, and washing it thoroughly with boiling alcohol, it should, after drying, weigh not more that 0.8 Gm. (limit of sodium carbonate, etc.); of this residue not more than 0.2 Gm. should be insoluble in water (limit of silica and other accidental impurities). If a solution of 5 Gm. of soap in 50 Cc. of hot water be mixed with 3 Cc. of tenth-normal oxalic acid solution, the subsequent addition of a few drops of phenolphthalein test-solution should not produce a pink or red tint (limit of alkalinity).—U. S. A solution of 1 Gm. of medicinal soap in 5 Cc. of alcohol, prepared with aid of a gentle heat, should not be reddened by addition of 1 drop of phenolphthalein solution, and not be affected by addition of hydrogen sulphide solution.—P. G. Although the Pharmacopœia allows as much as 36 per cent. loss of moisture, good air-dry Castile soap, as a rule, does not contain more than 12 or 15 per cent. of water.

Pharmaceutical Preparation.—Soap Liniment, Soap Plaster, U. S. P.

Action and Uses.—Soap is mildly laxative and antacid. As a laxative it is rarely used alone, but usually in combination with resinous or other laxative drugs, as scammony, aloes, rhubarb, etc., to enhance their activity and prevent griping. Because it is

so easily obtained, it is one of the best antidotes in poisoning by strong mineral acids, and should be freely administered in watery solution. In constipation, when hardened fecal masses are retained in the rectum or colon, a copious enema of soap suds forms one of the most efficient remedies that can be employed for its relief. If constipation is accompanied with much flatulence, the efficacy of the soap will be increased by the addition of oil of turpentine. A simple method of relieving constipation in young children is to insert a soap suppository into the rectum. The suppository should be dipped in water to make it slippery. Externally, soap is applied in alcoholic solution (Linimentum Saponis) to sprains and bruises, and sometimes in paste or thick lather as a local stimulant to chronic cutaneous eruptions. Soap is given in the dose of from 2 to 20 grains (0.12–1.30 Gm.).

Unofficial Soaps.—*Mottled Castile Soap* is obtained by adding a small quantity of ferrous sulphate to the cooling mass of olive soap, which causes greenish streaks to appear, and these afterward turn red on the surface of the soap. *Marine Soap* is made from cocoanut oil by boiling it with a calculated quantity of sodium hydroxide solution. It retains all the glycerin liberated from the fat, and forms a semitransparent mass which has the property of forming a lather with sea water, which ordinary soap does not do. *Rosin Soap* is usually made by adding ordinary rosin, to the extent of about 50 per cent. of the fat employed, to the mass in the soap boiler, toward the end of the process, the result being a yellow, smooth product. *Transparent Glycerin Soap* may be made by melting together 10 parts each of tallow, cocoanut oil, and glycerin, and 6 parts of castor oil, heating the mixture to 50° C. (122° F.), adding 12 parts of 40 per cent. sodium hydroxide solution and 12 parts of 95 per cent. alcohol, and stirring until the mass becomes transparent, after which a small quantity of sugar is usually added, and also the desired flavoring. Cocoanut oil has the property of being easily saponified at a temperature far below that of boiling water, and forms a hard soap, firmly retaining the glycerin which has been liberated.

Medicated Soaps.—While soaps intended simply as detergents may, without detriment, contain a very slight excess of alkali, it is desirable when medication of the soap is intended that, prior to its application, a perfectly neutral substance be employed; it has, in fact, been found that soap containing uncombined fat is even preferable to neutral or normal soap, for not only does it render the skin softer, but reaction between the soap and any medicinal agent added is also thereby avoided, or at least retarded. Such soaps, containing an excess of fat, are known as *Superfatted Soaps*, and have been largely used for the past 15 or 20 years. In preparing them it is customary to add an excess of 3 or 5 per cent. of fat or fixed oil in the beginning of the operation, which then remains intimately mixed with the newly formed soap. In a few cases the excess of fat has been incorporated with the freshly made neutral soap while yet in a soft, pasty condition. Both olive oil and lanolin are used in the manufacture of superfatted soaps, having been found preferable to all other fats in their action on the skin and toward chemicals.

In the manufacture of medicated soaps, the plan followed is identical with that for ointments. The medicinal agent is first intimately mixed (either in the form of solution or impalpably fine powder) with a small portion of the superfatted soap by means of suitable apparatus, which mixture is then added to such a further quantity of the same vehicle as may be necessary to establish the required percentage strength of the finished product. Among the various medications of superfatted soaps are tar 5 per cent., sulphur 10 per cent., salicylic acid 5 per cent., borax 5 per cent., carbolic acid 5 and 10 per cent., corrosive sublimate 0.1 and 0.5 per cent., camphor 5 per cent., and others.

SAPO ANIMALIS, *Br.*—Curd Soap.

Sapo sebacinus; Sapo domesticus; Savon animal, Fr. Cod.; *Animal soap, Tallow soap, Stearin soap*, E.; *Talgseife, Stearinseife, Hausseife*, G.

Soap made with sodium hydroxide and a purified animal fat, consisting principally of stearin; containing about 30 per cent. of water.—Br.

Preparation.—No process of manufacture is given in the Brit. Pharm., but the general directions given in the preceding article may be followed. Beef-tallow is generally employed, and mutton-suet may likewise be used, care being taken to thoroughly cleanse the fat and remove all adhering membrane. The Fr. Cod. directs that 500 Gm. of tallow be melted in the presence of 1000 Gm. of distilled water and, while stirring, 250 Gm. of 29 per cent. sodium hydroxide solution be added and the heat continued until complete saponification has been effected. 100 Gm. of sodium chloride are then added and heat continued until the soap has separated, after which it is removed when cold, washed with water and dried.

Properties and Tests.—Curd soap occurs in firm white or very light-grayish masses or cakes. It is dry and nearly inodorous, becoming readily pulverizable when exposed in warm air, and is easily molded when heated. While only slightly soluble in cold water, it dissolves more readily in hot water, undergoing hydrolysis into an acid soap (which is partly deposited on cooling) and free alkali. It is soluble in 90 per cent. alcohol, more freely when heated, and the latter solution upon cooling congeals to a semi-transparent gelatinous mass. The Brit. Pharm. demands the absence of free alkali and prescribes the following test, in which hydrolysis is prevented by the use of alcohol as a solvent: 5 Gm. of the dried and powdered soap, digested in boiling 90 per cent. alcohol, filtered while hot, and the filter washed thoroughly with more boiling alcohol, should yield a filtrate which does not afford a red or pink coloration with solution of phenolphthalein. "If the filter from the previous operation be washed with hot water, a solution is obtained which, on adding phenolphthalein solution, should not require more than 3 Cc. of tenth-normal sulphuric acid to discharge the resulting red color (limit of alkali carbonate). Curd soap should not impart a greasy stain to white unglazed paper (absence of free oil and fat). When incinerated it should not yield an ash which deliquesces (absence of potassium soap). It should lose about 30 per cent. of moisture when dried at 110° C. (230° F.)."—Br. Curd soap may be readily distinguished from the official olive oil soap by its lesser solubility in water, and especially by the character of the fatty acids separated when a solution of 5 Gm. of the soap in shavings or powder in 100 Cc. of hot water is treated with diluted sulphuric acid until an acid reaction ensues. The fatty acids, being insoluble, will rise to the surface, and upon cooling will form a hard cake in the case of animal soap, and a soft or semiliquid mass in the case of olive oil soap, the former melting at 45° to 50° C. (113°–122° F.), and the latter at or below 25° C. (77° F.).

Uses.—Pharmaceutically, curd soap is of importance in the manufacture of certain preparations for external use, such as the liniment of soap and potassium iodide and solid opodeldoc, where its sparing solubility in water and hydro-alcoholic liquids is taken advantage of to produce solid liniments which will liquefy at the temperature of the body.

SAPO MOLLIS, *U. S., Br.*—Soft Soap.

Sapo kalinus, P. G.; *Sapo viridis.—Green soap*, E.; *Savon mou, Savon vert*, Fr.; *Kaliseife, Grüne Seife*, G.

Preparation.—Linseed oil, 400 Gm.; potassium hydroxide, 95 Gm.; alcohol, 40 Cc.; water, a sufficient quantity. Heat the linseed oil in a deep, capacious vessel, on a water-bath or steam-bath, to a temperature of about 70° C. (158° F.). Dissolve the potassium hydroxide in 450 Cc. of water, warm the solution to about 70° C. (158° F.), add it to the linseed oil and mix thoroughly; then incorporate the alcohol and continue the heat (without stirring) until a small portion of the mixture is found to be soluble in boiling water without the separation of oily drops. Then allow the mixture to cool, and transfer it to suitable vessels. The potassium hydroxide used in this process should be of the full strength directed by the Pharmacopœia (85 per cent.). Potassium hydroxide of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken, the proper amount for the above formula being ascertained by dividing 8075 by the percentage of absolute potassium hydroxide contained therein.—U. S.

The Br. P. gives no process of manufacture, but directs soft soap to be made from olive oil and potassium hydroxide. The directions of the P. G. are almost identical with those of the U. S. P.

In place of linseed oil or olive oil, other oils have been used at different times with the object of producing a soap less disagreeable in odor or more decidedly green in color than the official article. Cottonseed oil will yield an almost colorless soap, but its odor is less objectionable than the linseed oil soap. Malaga olive oil, which itself possesses a decided green color, produces a green or, at least, a yellowish-green soap, while hempseed oil yields a much greener soap. Some manufacturers, judging from the dark-green color of their product, perhaps add some coloring-matter, as indigo, which, when mixed with the yellowish soap, forms a deep-green color. As will be seen below under *Properties*, official soft soap has no green color, but in some localities physicians demand a dark-green color, which was characteristic of the green soap formerly imported in large quantities from Germany.

Properties.—Soft soap occurs as a soft, unctuous, yellowish-brown (yellowish-white to yellowish-green, Br.) mass, having a characteristic odor (almost inodorous, Br., slight soap-like odor, P. G.), and an alkaline taste. An aqueous solution shows an alkaline reaction to red litmus-paper. It is soluble in hot water to a nearly clear liquid; also in alcohol without leaving more than 3 per cent. of residue (limit of potassium carbonate, insoluble soaps, etc., Br.). If to a solution of 5 Gm. of soft soap in 50 Cc. of water 2 drops of phenolphthalein test-solution be added, not less than 2.3 Cc. nor more than 4.5 Cc. of tenth-normal oxalic acid solution should be required to discharge the red tint (limit of free alkali).—U. S. The P. G. requires that a solution of 10 Gm. of soft soap in 30 Cc. of alcohol, after addition of 0.5 Cc. of normal sulphuric acid, shall not give a red color upon further addition of 1 drop of phenolphthalein solution.

Besides the above product, an inferior article is recognized in the P. G. under the name *Sapo Kalinus Venalis—Schmierseife*, which no doubt is of variable composition and made from mixtures of linseed oil, rapeseed oil, fish oil, hempseed oil, etc. It forms an almost clear solution in water, and should yield at least 40 per cent. of fatty acid when tested as follows: To a solution of 5 Gm. of the soap in 100 Cc. of hot water add 10 Cc. of diluted (16 per cent.) sulphuric acid, and heat the mixture on a water-bath until the separated fatty acid floats as a clear layer on the surface. When cool add 50 Cc. of petroleum benzin, and dissolve the fatty acid by agitation. If 25 Cc. of the solution be evaporated to constant weight at a temperature not exceeding 75° C. (167° F.), the residue should weigh not less than 1 Gm.—P. G.

Pharmaceutical Preparations.—Liniment of Soft Soap.—U. S. P.

Action and Uses.—Soft soap is used for cleansing purposes and as a stimulating application to chronic sluggish skin diseases, notably eczema rubrum, psoriasis, ichthyosis, and lupus. For this purpose the tincture of green soap (Linimentum Saponis Mollis) is applied over the diseased area until some slight inflammatory reaction is set up, when the soap is removed by thorough washing and a bland ointment applied.

SAPONARIA.—Soaproot; Soapwort.

Saponary, Bruise-wort, Bouncing-bet, Sweet Betty, Scourwort, Wild Sweet-William, Latherwort, etc., E.; *Seifenwurzel*, G.; *Savonnière*, Fr.; *Saponaria*, Sp.

The dried roots and smaller rhizomes of *Saponaria officinalis* L. (Fam. *Caryophyllaceæ*).

Origin.—This plant is a perennial herb a foot or two high, native of Europe and naturalized in North America, where it grows in the greatest abundance, in many localities, along roadsides and about old buildings. Its habit is shown in the accompanying illustration. The flowers vary in color from rose pink to nearly white.

Fig. 364.

Saponaria (½ Nat.).

Description.—The root, which should be collected in the spring or autumn without the creeping runners, is 25 to 38 Cm. (10 to 15 In.) long, cylindrical, about 3 to 6 Mm. (⅛ or ¼ In.) thick, gradually tapering below, somewhat branched, longitudinally wrinkled, and of a red-brown color externally. It breaks with a short fracture, and is internally white, with a rather thick bark and a soft yellowish, and in the centre whitish, wood which has nomedullary rays, and is surrounded by a fine dark-colored cambium-line. The root is inodorous, and has a sweetish and bitter, afterward persistently acrid, taste.

Constituents.—Until recently, saponaria was supposed to contain but one active constituent, an amorphous neutral glucoside, to which the name *saporubrin* had

been given, and which is described at length in Van Rijn's excellent work entitled *The Glucosides* (Berlin, 1900). Kobert, who has again investigated the subject, has been able to determine the presence of two constituents closely resembling those found in soap bark (see under QUILLAJA), and has designated them as *saporubrin* and *saporubric acid* respectively. The former is not affected by neutral lead acetate, nor by ammonium sulphate, but is precipitated from its aqueous solution by basic lead subacetate. Saporubric acid is precipitated by ammonium sulphate, and its presence in soapwort was determined by Kobert in this way.

Action and Uses.—The physiological action of saponin, the active ingredient of soapwort, bears no relation to the former application of the drug as an alterative in chronic cutaneous diseases, syphilis, gout, and rheumatism. It is probably without influence in these diseases. It has been administered in decoction (1 ounce to 1 pint [30 Gm.–480 Cc.]), the dose of which was 1 to 2 ounces (30–60 Cc.).

Allied Products.—Under the title CARYOPHYLLACEÆ, reference has been made to the general presence of saponin in the plants of this family. Two of these yield commercial drugs of more or less importance, as follows :

Levant or *Spanish soaproot* is the root of *Gypsophila Struthium* L., collected in the Mediterranean region. It is about 30 Cm. (12 In.) long, 5 Cm. (2 In.) thick, transversely and longitudinally wrinkled, pale-brownish externally, internally white, with a rather hard wood and numerous medullary rays. In sensible properties and in composition it resembles the preceding.

Red Sand-spurry or *Sandwort* (*Arenaria rubra*, Fr. Cod.) is the herb *Tissa rubra* (L.) Britton (*Arenaria r.*—L.; *Buda r.*—Dumort; *Spergularia r.*—Presl.), an Old World species, naturalized in sandy regions in many parts of eastern and central North America. It has a prostrate stem, opposite, linear, gray-green leaves, lanceolate, cleft stipules, small pink flowers, and 3-valved, many-seeded capsules; odor and taste slight. Vigier (1881) obtained from the plant a stearopten and some odorous resin; the decoction is stated to have an alkaline reaction. The commercial drug, as used in France, consists of a number of allied species.

Sapindaceæ.—This family, which contains, according to Radlkofer, 118 genera and almost exactly 1000 recognized species, is noted for the prevalence in its plants of saponin, on which account a great many of them are used as fish-poisons and several as drugs. The family yields a number of edible fruits, the most important being the Oriental *Lichee*, or "Chinese fruit," derived from various species of *Nephelium*.

Soap-berries, the fruits of various species of *Sapindus*, have been found to contain as much as 35 per cent. of saponin. These fruits are nearly spherical, usually about 1.2 Cm. in diameter, from yellow to deep-brown-red in color, wrinkled on drying, and consist of a soft, gummy pericarp containing a single large seed, a considerable space separating the two. The fruit has a bitter, sweetish, and acrid taste. The species most commonly used is *S. Saponaria* L. *Cardiospermum Halicacabum* L., the common *Balloon-vine*, *Heart-seed* or *-pea*, or *Indian-heart*, of cultivation, wild in nearly all tropical countries, and *Dodonœa viscosa* Jacq., also common in all tropical regions, are used as purgatives and expectorants, and also for washing purposes, on account of their saponin.

SAPONINA.—Saponins.

The first use of the name saponin occurred in connection with the saponaceous constituent of the root of Saponaria rubra, discovered in 1808 by Schrader. While formerly the view prevailed that the peculiar substance called saponin, as found in different plants, is identical, careful investigation of the subject by R. Kobert and his associates and pupils has demonstrated the fact that the name saponin should be applied to a group of plant constituents having certain chemical and physical properties in common, yet differing in constitution, physiological effect, etc.

Although saponins are met with in several hundred plants, both monocotyledons and dicotyledons, distributed among 46 or more families, practically nothing is known regarding the important part they may play in plant physiology. They occur in all parts of plants; thus in the root of sarsaparilla, saponaria, senega, and helonias (chamælirium), the bulb of cyclamen, the bark of quillaja and guaiacum, the fruit of sapindus, the seed of æsculus, entada, and agrostemma, the stem of dulcamara, and the leaves of digitalis and guaiacum. Kobert inclines to the view that the saponins are formed in the leaves and deposited later in other parts of the plant.

One of the chief characteristics of the saponins, and to which they owe their group name, is the property of forming aqueous solutions which foam strongly upon agitation,

like solutions of soap, even when very dilute (1 in 10,000). The bubbles of froth, which in some cases are quite persistent, are destroyed if alcohol or ether be allowed to drop upon them. Another common property is the ability to hold fatty and resinous substances, when in a finely divided state, in perfect suspension in aqueous mixtures, thus producing emulsions of great stability. Finely divided vegetable substances are also kept in suspension in watery fluids by the presence of saponins. With few exceptions the saponins are readily soluble in water (all are soluble if the water be made slightly alkaline), and also in diluted alcohol, preferably if warmed. Some are soluble in cold absolute alcohol, but thus far none has been found soluble in ether, benzene, or carbon disulphide. A few dissolve with difficulty in chloroform. Many, but not all, saponins are precipitated from their solutions by addition of a saturated solution of ammonium sulphate, and this fact has been utilized as a means of separation. In some instances precipitation occurs in the cold, immediately or after the lapse of some time, while in others the application of heat is necessary, especially in weaker solutions. By this method it has been possible to separate polygalic acid from senegin in a decoction of senega, quillajic acid from quillajasapotoxin in a decoction of soap-bark, and saporubric acid from saporubrin. The sapotoxin present in Levant soapwort, *saponaria alba*, which is precipitated by ammonium sulphate, has thus been shown not to be identical with the sapotoxin in quillaja.

All saponins have glucosidal properties, and are hydrolyzed when their solutions are heated with dilute mineral acids, being split up into dextrose and a non-toxic body, soluble in cold water, called sapogenin. The latter body, which is not identical for all saponins, has acid properties, and forms water-soluble crystallizable salts with the alkalies. Some saponins are precipitated by neutral lead acetate, others by basic lead subacetate, and still others are affected by both reagents. Those precipitated by neutral lead acetate show an acid character toward litmus and Congo-red, and are designated as acids; thus, melanthinic acid, polygalic acid, quillajic acid, etc. The other saponins are neutral, some being known as sapotoxins, while others have been given specific names, such as assamin, chamælirin, senegin, etc. One drug, at least, is known to contain 3 neutral saponins—namely, sarsaparilla, the same being named parillin, sarsasaponin, and smilasaponin.

As a rule, saponins are amorphous bodies, but parallin and sarsasaponin are crystalline. They are characterized by a bitterish, acrid taste, sometimes accompanied by a burning sensation, and in fine powder are intensely irritating and sternutatory. With few exceptions saponins are decidedly toxic and have a solvent effect on red blood-corpuscles. This poisonous property prevents their use in pharmacy in many cases, where their property of permanently suspending oils and resinous matter would otherwise make it very desirable. The saponin obtained from the root of helonias dioica, and known as chamælirin, is said to have been used at times for codliver oil emulsions because less toxic than the saponins of quillaja bark; but inasmuch as the saponins present in guaiacum bark and leaves have been found almost entirely devoid of toxic properties, these would naturally seem preferable to all others for emulsifying purposes.

The following color reactions observed by Kobert are worthy of special note: A characteristic red coloration occurs with many saponins if they are mixed with concentrated sulphuric acid and exposed to the air for some time, or carefully warmed. With an alcoholic solution of sulphuric acid, to which a drop of dilute solution of ferric chloride has been added, a greenish-blue coloration is produced, which reaction is useful for detection of saponins in microscopic sections of vegetable drugs. A solution of selenous acid in concentrated sulphuric acid (Mecke's reagent) produces a cherry-red color with the acid saponin of *cereus grandiflorus* and other saponins, while a beautiful violet color is produced with guaiac-saponic acid. A very delicate reaction, resulting in an intense red color, is produced by adding to soap-bark saponins some Millon's reagent as modified by Nasse (a solution of mercuric acetate to which a drop of potassium nitrite solution has been added just before using), and warming. Kobert states that this last reaction is useful for detection of quillaja preparations in oil emulsions.

Two general formulas have been proposed to represent the composition of the saponins, C $H_{2n-10}O_{18}$ by Flückiger, and $C_nH_{2n-8}O_{10}$ by Kobert, to one of which nearly all known saponins may be referred. To the first group belong quillajic acid $C_{33}H_{56}O_{18}$, chamælirin $C_{36}H_{62}O_{18}$, parillin (Flückiger) $C_{40}H_{70}O_{18}$, digitonin $C_{33}H_{56}O_{18}$, sarsasaponin $C_{40}H_{70}O_{18}$, and others, while quillajasapotoxin $C_{17}H_{26}O_{10}$, melanthinic acid $C_{29}H_{50}O_{10}$, sen-

egin $C_{18}H_{28}O_{10}$, smilasaponin $C_{20}H_{32}O_{10}$, polygalic acid $C_{19}H_{30}O_{10}$, and the acid and neutral saponins of guaiacum bark, $C_{21}H_{34}O_{10}$ and $C_{22}H_{36}O_{10}$, are members of the second group.

Inasmuch as the saponins are capable of forming insoluble lead compounds, Kobert recommends the following method for their extraction: To the concentrated decoction or tincture of the drug, solution of lead acetate is added; the resulting precipitate, after filtration, is mixed with some alcohol, treated with hydrogen sulphide, and again filtered. The residue is boiled with several portions of alcohol, the solutions added to the filtrate, and the whole evaporated to a syrupy consistence. Upon addition of ether to the cooled liquid, the saponins are precipitated. In order to recover any saponin not precipitable by lead acetate, solution of basic lead subacetate should be added to the original filtrate and the process then continued exactly as directed for the treatment of the precipitate obtained with neutral lead acetate.

The process of salting out by means of ammonium sulphate may also be employed for precipitation and separation of saponins (as given under QUILLAJA) in place of the lead acetate method mentioned above.

Due acknowledgment is hereby made of the recent very interesting and valuable publication by Professor R. Kobert, of Rostock, Germany, entitled "Contributions to the Knowledge of the Saponin-Substances," from which the above brief abstract has been made.

Action and Uses.—The saponins as isolated principles are not used in medicine, but they represent the active ingredients of many medicinal plants, as sarsaparilla, senega, quillaja, etc. As a class they possess distinctly irritating properties. Applied to the skin in the form of ointment, they set up an inflammation characterized by itching, heat, redness, and eventually pustulation. Their solutions injected into the subcutaneous tissues produce local anæsthesia, not, however, until they have caused so much irritation as to preclude their use for this purpose. Their irritant local action on the nasal and bronchial mucous membranes causes sneezing and coughing, while nausea and vomiting result from their effect upon the membranes of the mouth, pharnyx, and stomach. Some of the saponins (sapotoxins), notably those derived from quillaja, cyclamen (sowbread), and agrostemma (corncocle), are exceedingly poisonous, while others, from senega and sarsaparilla, are less toxic. Large quantities injected into the blood stream prove rapidly fatal, death being due to paralysis of respiration, the heart continuing to beat for some time after respiratory arrest. Smaller lethal doses similarly administered produce general depression, loss of appetite, an enfeebled and irregular circulation, convulsions, collapse, and death. The post-mortem changes after these smaller lethal doses are widely disseminated extravasations of blood into the serous and mucous membranes. Large quantities given by the mouth, even if they do not produce vomiting, are rarely fatal, as most of the saponins are not absorbed through an intact mucous membrane. The saponins in concentrated solution are powerful poisons to all living protoplasm. They induce paralysis and alterations in structure if applied directly to muscle. Nervous tissue is similarly affected. When brought in contact with red blood corpuscles, either within the vessels or extravascularly, the saponins destroy the cells and liberate the hæmoglobin. The therapeutic applications of the different saponins are discussed under the drugs from which they are derived.

SAPOTACEÆ.—The Sapota Family.

The Sapota, or Gutta-percha family, comprises 31 genera and about 350 species of tropical trees and shrubs. It is chiefly interesting as being the source of the important resinous substances Gutta-percha, Balata, Chicle, and many similar substances, and because it yields many important tropical fruits.

Bassia oil is the fat extracted from the seeds of various species of *Bassia*. That from *B. butyracea* Roxb. is known as *Fulwa-butter*. These fats are used externally in the treatment of rheumatism, in India, as are the similar substances obtained from the seeds of various species of *Payena*. *Bassia longifolia* L. is of interest as being one of the few plants whose flowers are used as foods. It is known in India as the *Mahwa*, *Elloopa*, and by various other names.

Monesia or *Monesia Bark* is the dried bark of *Chrysophyllum glyciphlœum* Casaretti, a Brazilian tree. The bark is in flat or curved pieces 3 to nearly 6 Mm. (⅛ to ¼ In.) thick, often 5 to 7 Cm. (2 or 3 In.) broad, externally marked with confluent ridges, forming large irregularly quadrangular or hexagonal meshes, which are covered with a thin, smooth, whitish

tissue while the bark is young. The inner surface is cinnamon-colored, and longitudinally striate, otherwise smooth. The bark is very hard, breaks with a granular fracture, and shows in the interior alternate layers of brown and pale-reddish tissue. It is inodorous and has a peculiar taste, which is at first sweet like liquorice, afterward bitterish, somewhat acrid and astringent. It contains tannin, glycyrrhizin, and saponin, with a trace of volatile oil, coloring-matter, and other substances of no medicinal interest.

Sideroxylon Cantoniense Lour. yields the Chinese bark *Shan-kan-shii*, much used as a tonic and astringent. The unripe fruits of many species are also used as astringents, like persimmons.

SARSAPARILLA, *U. S.*—Sarsaparilla.

Sarsæ radix, Br.; *Radix Sarsaparillæ*, P. G.; *Sarsaparilla*, G.; *Salsepareille*, Fr.; *Salsapariglia*, It.; *Zalzaparilla*, Sp.; *Salsa Americana*, *Salsaparrilha*, Port.

The dried root of *Smilax medica* Chamisso et Schlechtendal (Mexican, Vera Cruz, or Tampico Sarsaparilla), *Smilax ornata* Hooker f. (Jamaica, Central America, Costa Rica, or Lima Sarsaparilla), *Smilax papyracea* Duhamel (Brazilian, Para, or Rio Negro Sarsaparilla), or *Smilax officinalis* Kunth (?), known commercially as Honduras Sarsaparilla (Fam. *Liliaceæ*).

Sarsaparilla is official in all pharmacopœias, most of which recognize one or more of the species above named, though they differ greatly in their preferences, most of them preferring the Honduras variety, and most allowing "other undetermined species also." The B. P. recognizes only *S. ornata* Hook. f.; the Italian recognizes *S. syphilitica* Kunth, and states that the best varieties are those with bark and pith relatively small; the Belgian rejects those which are pale, blackish inside, or tasteless.

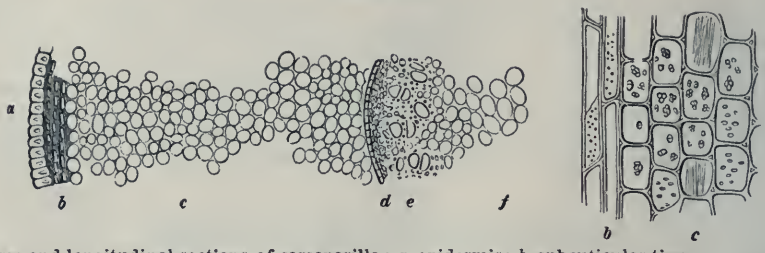
Origin.—The genus *Smilax*, Tourn., contains some 200 species, both of the Old and New Worlds. Several are common in our northeastern States, and are known as *Greenbriar*, *Catbriar*, *Bread-and-butter vine*, etc. They are tough and strong, though slender, woody and sharply thorny climbers, with smooth and shining coriaceous leaves, the stipules formed into tendrils. They produce umbels of small, 3-merous, greenish flowers and blue-black berries, the latter often red in the tropical species. The northern species are scarcely medicinal, though the root of our common *S. rotundifolia* L. (*S. caduca* L.; *S. quadrangularis* Willd.) is somewhat used as an alterative. Those of our Southern States are somewhat medicinal, and several of the tropical species, beginning with those of Mexico, become important drugs. They resemble the northern in habit, but are very much larger, often climbing or running for hundreds of feet. The strong rhizomes also frequently run near or at the surface of the ground for a great distance, giving off at their nodes fascicles of slender roots which are themselves often several yards in length, and of nearly uniform thickness throughout most of their length. Those of the different species differ greatly in the number and character of the small lateral rootlets which they produce. The rhizomes are torn up at those seasons when the ground is soft. The fascicles of roots are cut away, with or without short sections of their rhizome, according to the custom of the respective locality, and are dried and variously bundled or baled. (See *Varieties.*) The collector usually bundles it but loosely, the compact rolls of commerce being afterward formed by the native dealer.

Description.—Mostly more than a meter (more than a yard) in length and 4 to 6 Mm. ($\frac{1}{8}$ to $\frac{1}{4}$ In.) thick, with few or many fine roots adhering; externally varying from light-gray-brown and smooth, with few deep and sharp wrinkles, to dark- or orange-brown and less smooth, and with more and smaller wrinkles; internally whitish, with a thick, mealy, or sometimes horny cortex, a circular wood-zone and a thick pith; fracture tough; nearly inodorous; taste mucilaginous, somewhat sweetish and bitter, slightly acrid.

The thick, woody, knotty rhizome, if present, should be rejected.

The transverse section exhibits an epidermis of one layer of cells; a subcuticular layer of two or three layers, the cells axially elongated and with thickened walls; a cortex of many parenchymatic layers containing starch in grains or in a pasty mass, some of the cells containing raphides; an endoderm (*nucleus-sheath* or *bundle-sheath*) of one layer of cells, their form and thickening characteristic in the different species; a woody zone, the vessels of the scattered bundles large and radially arranged; a central parenchyma called *pith*, similar to the cortex and containing starch, a few vascular bundles often scattered through it.

Fig. 365.



Transverse and longitudinal sections of sarsaparilla: *a*, epidermis; *b*, subcuticular tissue; *c*, parenchyma; *d*, nucleus-sheath; *e*, woody zone; *f*, central parenchyma.

Varieties.—The more important varieties are the following:

Honduras.—The botanical origin of this is undetermined, but it is commonly believed by medical botanists that it is derived from *S. officinalis*, originally collected in New Grenada. It is collected in Honduras, Guatemala, etc., the rhizome entirely excluded, the roots folded and bound very tightly into cylindrical rolls about 2½ feet long and 3 inches in diameter, the exposed doubled ends not trimmed off, otherwise entirely covered by the binding root; the color a rich brown; the roots of medium thickness, bearing

Fig. 366.

Honduras sarsaparilla.

Fig. 367.

Honduras sarsaparilla (× 3).

many small longitudinal wrinkles and an exceedingly variable number of rootlets. The endodermal cells are nearly uniformly thickened on all sides, and have a nearly quadrangular appearance in transverse section. The cortex and medulla are relatively thin, and the cells well filled with granular starch. The Mexican variety is often falsely rolled

Fig. 368.

Jamaica sarsaparilla.

Sections through nucleus-sheath, showing above one row of cells of bark-parenchyma, and beneath it several rows of cells of the woody zone (× 80).

to imitate the Honduras, besides which a variety is largely exported from Honduras, collected there and rolled in the same way, which is closely similar to the Central American Jamaica article.

Central American Jamaica, Costa Rica, or Lima.—This is the product of *S. ornata* Hook. f., and is collected chiefly in Costa Rica. It came to be called "Jamaica" from being exported through that province. It is tied into rolls a little larger but far looser than the last, and the binding root is passed around it only a few times. The doubled ends are not trimmed off. Much of it also comes pressed into large bales. The rhizome

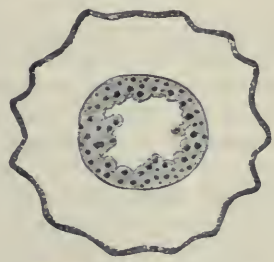
is entirely excluded. It is considerably darker than the last, and the roots are distinctly thinner and leaner, and are strongly clothed with rather coarse rootlets. It is much more sharply wrinkled and not nearly so well supplied with granular starch. Its taste is rather muddy and not so good as that of the Honduras. Its cortex is relatively thick; its endodermal cells much narrowed inwardly, as to the lumen, by the greater thickening of the walls there.

Native Jamaica (*Roja Inglesa*).—This is the product of *S. utilis* Hemsly (long called *S. officinalis*), from plants cultivated in Jamaica. Though sometimes baled, it is usually put up like the last variety, the rolls commonly somewhat shorter and thicker. It is of an orange or orange-red color and of beautiful appearance, thick and moderately

FIG. 372.

Native Jamaica sarsaparilla.

FIG. 373.



Jamaica sarsaparilla (× 4).

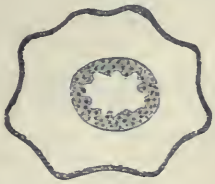
wrinkled and well supplied with rootlets. Its structure is much like that of the last. A variety occasionally exported from Venezuela (*Caracas sarsaparilla*) is possibly the same, and, if so, this is doubtless the original source of the Jamaica cultivated.

Mexican (*Vera Cruz or Tampico*).—This is from *S. medica*. Most of it is now baled, but a good deal is also put up in loose rolls, slightly bound, the doubled ends not

FIG. 374.

Mexican sarsaparilla.

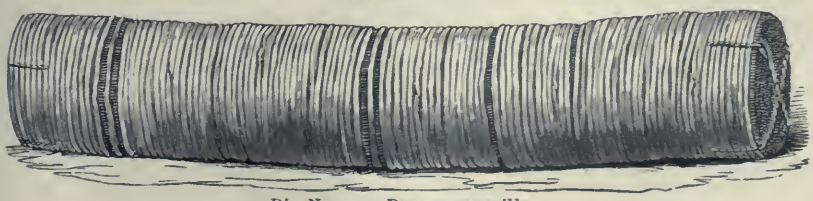
FIG. 375.



Mexican sarsaparilla (× 3).

trimmed off, one end much larger, owing to the presence of one or more nodes of the rhizome for each fascicle of roots, in which particular it differs from all others. The root is distinguished by its few and extremely deep wrinkles, its pale color, freedom from rootlets, and smooth surface. It contains comparatively little granular starch. The endodermal cells are nearly quadrangular, their walls rather more thickened internally, and their lumen nearly oval.

FIG. 376.



Rio Negro or Para sarsaparilla.

Rio Negro, Brazilian, or Para.—This is from *S. papyracea*. It comes in enormous, very tight rolls, about 4 feet long by a foot in diameter, completely covered by a binding

vine, the doubled ends trimmed smoothly off. It is very dark, the roots of medium thickness, with numerous small wrinkles, abundantly clothed with fine rootlets and very starchy. It has a thin cortex, and the endodermal cells are large, radially elongated, and with a large lumen.

Fig. 377.

Rio Negro sarsaparilla (× 3).

Constituents.—Sarsaparilla contains about 3 per cent. of saponin-like substance, which is separable into 3 glucosides, up to 15 per cent. of starch, a little resin, volatile oil, pectin, calcium oxalate, and other unimportant substances. Of these, the first named undoubtedly represents all that is important in the activity of the drug. The most important of its 3 bodies is *sarsasaponin* ($C_{22}H_{36}O_{10}$), which is crystallizable, and soluble in water and alcohol, especially on warming, as are both the others. *Parillin* ($C_{26}H_{44}O_{10}$) is also crystallizable. *Smilasaponin* ($C_{20}H_{32}O_{10}$) is not crystallizable. Sarsasaponin is regarded as 3 or 4 times more active than the other two. "Smilacin" is a name which has been applied to both of the last two. Some attempts have been made to determine the relative amounts of total glucosidal constituents in the several varieties, but the results are not conclusive.

Pharmaceutical Preparations.—Compound Fluidextract of Sarsaparilla, Compound Syrup of Sarsaparilla, Fluidextract of Sarsaparilla, U. S. P.

Action and Uses.—No drug in the materia medica has been the subject of so much discussion as to its efficacy as has sarsaparilla. Since its introduction into medicine during the sixteenth century as a remedy in syphilis, it has been regarded by some as almost a specific, and denounced by others as entirely inert. There is certainly no relation between its physiological action and the power that it seems to possess over the general system. When given alone it exercises little influence, but in combination with mercury or the iodides it seems to increase their efficiency in the treatment of cases of obstinate syphilis which fail to yield to them alone. It is claimed to be of particular service in subjects debilitated by the ravages of syphilis and the injudicious use of mercury and iodine. The compound decoction of sarsaparilla has been recommended in chronic gout and rheumatism and in certain sluggish skin diseases. Sarsaparilla is largely used in domestic medicine as a "blood purifier," and is perhaps the least important ingredient of many patent medicines which bear its name. The compound syrup, in the dose of 1 to 4 drachms (4–16 Cc.), is the preparation commonly administered. The fluidextract is given in the dose of ½ to 1 drachm (2–4 Cc.).

Other Sarsaparillas and Substitutes.—The most important species, next to those above considered, are *S. China* L. and *S. glabra* Roxb. (*Radix Chinæ, China root; Chinawurzel, Pockenwurzel, Chinaknolle*, G.; *Squine*, Fr. Cod.; *Choh-chini*, Ind.; *Too-fuh*, Chin.; *Sankira*, Jap.), of eastern Asia, including Japan. It is used in its home very much like Sarsaparilla, but is of totally different appearance, consisting of root-tubercles. They are irregularly oval, flattened, rusty brown externally, white or pinkish internally, starchy and without much odor or taste. They are often peeled before being marketed. No notable constituent except a glucoside was found by Prof. David Hooper. *S. ovalifolia* Roxb. is also an Indian species, and its root resembles Sarsaparilla, and is there used as such. *Smilax Pseudo-China* L. and *S. tamnoides* L., of the southeastern United States, yield tuberous roots, *Bamboo-briar root*, which somewhat resembles the China root, but they are not so heavy and are of a light-brown color. A similar article is used in Mexico as *Raiz de China de Mexico* (*Mexican China-root*). Its origin is not determined. *S. aspera* L., of southern Europe, is similarly used. We have recently seen a very slender, blackish root, bearing sharp conical projections, which is used as a sarsaparilla in Honduras. It is apparently from a Smilax. A somewhat similar one, apparently not a Smilax, is so used in Santo Domingo.

Among the Sarsaparilla-substitutes not of the genus *Smilax* is the root of an *Agave*, collected in Porto Rico, and called Porto Rico Sarsaparilla. The gall-covered root of a *Philodendron* was reported as being sold in Hamburg as a sarsaparilla-substitute. In India, the root of *Hemidesmus Indicus* Br. (*Indian Sarsaparilla*) is extensively used. Like sarsaparilla, it is a long, slender root, but is tortuous, dark-brown or purplish-brown, longitudinally fissured, with the odor of cumarin, which it contains, and of a sweetish and acrid taste. Its structure is dicotyledonous, and the bark contains numerous laticiferous ducts. The rhizome of *Carex arenaria* L. (*Sand-sedge, German sarsaparilla*, E.; *Laiche*, Fr.; *Sandriedgras, Rothe Quecke*, G.—Fam. *Cyperaceæ*) is similarly used, as is *C. hirta* L. Greenish, in 1894, reported the importation to England of the slender rhizomes of some ferns, thought to be perhaps *Pteris aquilina* L. and sold as Sarsaparilla, and he refers to the early similar use of *Polypodium Colaguala* Goebel et Kuntze, in Peru.

SASSAFRAS, *U. S.*—Sassafras.

Cortex Sassafras, Swiss P.—*Sassafras bark*, *Saxifrax*, E.

The dried bark of the root of *Sassafras Sassafras* (L.) Karsten (*Laurus S.* L.; *L. variifolius* Salisb.; *Sassafras v.* Kuntze; *S. officinale* Nees—Fam. *Lauraceæ*).

The Sassafras tree, sometimes known as *Cinnamon wood*, *Ague tree*, or *Saloop*, is represented, in one form or another, in most pharmacopœias. *Sassafras radix*, of the B. P. and of most other pharmacopœias, is defined as the dried root. *Lignum Sassafras* of the German Pharmacopœia (*Lignum pavanum* or *Lignum Fœniculi*, *Fenchelholz*, *Panamaholz*, *Sassafrasholz*) is defined as the wood of the root. A number of pharmacopœias specify that the trunk-wood should be rejected, though the Belgian includes it, and the Italian includes that of the lower portion of the trunk, and stipulates that it must contain 1.5 per cent. of volatile oil.

Origin.—Sassafras grows abundantly throughout the eastern and southeastern United States and to some extent in southern Canada, preferring a sandy or light soil and rather open situations. It is a dicœcious tree, ordinarily rather small, but occasionally exceeding 3 feet in diameter and 50 feet in height. The young twigs are green, soon developing brownish corky warts, and later becoming brown and fissured. The bark of the trunk is ashy-gray and deeply and roughly fissured. The branches contain a large pith (see SASSAFRAS MEDULLA). The root is large, very irregularly branched, externally of a creamy-white color when first exposed, but quickly changing to a gray. The wood of the root and trunk is at first whitish, becoming on exposure, especially the former, reddish- or rusty-brown. The form of the thickish, smooth, or when young somewhat downy, leaves is indicated in the accompanying illustration. Frequently they bear but a single lateral lobe. The flowers are of a light-yellow color and somewhat, especially those of the staminate tree, precede the leaves. The pedicle and basal portion of the fruit are of a bright crimson or scarlet, the drupe itself bluish-black. All parts are very mucilaginous. The bark of the branches is strongly aromatic, but quite bitter and of a different flavor from that of the root-bark.

FIG. 378.

Sassafras (branch, ½ Nat.; root-bark, Nat.).

Description of Root-bark.—In irregular, warped, chip-like fragments, 5 Mm. (⅕ In.) or less in thickness, the thicker pieces deprived of most of the gray corky layer; bright rust-brown, or with more or less of the gray-brown cork adhering and exhibiting its outer surface softly and rather finely scaly, from numerous short, intersecting, shallow fissures; inner surface obscurely short-striate; light, soft, and fragile, with a short, weak fracture which exhibits a broad, irregular, whitish layer between two rust-brown ones; strongly and peculiarly fragrant; taste sweetish and bitterish, aromatic, mucilaginous, and slightly astringent.

The stem-bark is in strips or elongated pieces, with a lighter-gray, more deeply and longer fissured outer surface, and is less aromatic, more mucilaginous, and bitter.

In the powder the parenchymatic cells are seen to be very thin-walled, almost always without pores and well-filled with starch grains, in which particulars they differ from those of the stem-bark. Furthermore, bast-fibers are very rare and are always completely detached. The starch-grains are mostly in groups. The single ones are lenticular and occasionally reach a diameter of 12 to 15 microns.

Constituents.—The important constituents of the official product are from 6 to 9 per cent. of volatile oil (see OLEUM SASSAFRAS), about 6 per cent. of tannin and 9 of *sassafrid*, together with a large amount of gum. A considerable amount of starch and

a little resin are also present. The tannin of sassafras bark gives a bluish-green color with ferric salts. It is gradually transformed by oxidation into sassafrid, which, according to Procter, is not present in the fresh bark. Sassafrid is soluble in alcohol, but not in ether, and crystallizes in yellowish-brown granules. Its solutions are colored red by alkalies, precipitated carmine-red by alkaline earths, dark greenish-brown by ferric salts, and whitish by lead acetate.

Other Parts of the Plant.—Sassafras wood of the root and lower portion of the stem yields an oil identical with that from the root-bark, but occurring in much smaller amount, usually between 1 and 2 per cent. The leaves and green bark of the twigs yield an oil which apparently does not contain saffrol, but is, on the contrary, more allied with lemon oil.

Sassafras Medulla, U. S., or Sassafras Pith, is the dried pith of the stem of the plant described above. It occurs in cylindrical, straight, curved or coiled pieces, 1 to several inches in length and 3 to 8 Mm. (⅛ to ⅓ In.) in diameter, or in split portions of the same; white, very light, and spongy; inodorous or with a slight odor, as well as taste, of sassafras, very mucilaginous.

Macerated in cold water, 2 Gm. in 100 Cc., it forms a mucilaginous liquid recognized in the U. S. P. as Mucilago Sassafras Medullæ.

Its only important constituent is a very large quantity of gum, forming with water a mucilage not precipitated by alcohol. It contains enough volatile oil to give it a faint sassafras odor and taste.

Action and Uses.—The bark of sassafras root possesses aromatic, stimulant, and astringent properties. It is used chiefly as a flavoring agent to mask the taste of less agreeable drugs. An infusion of 1 fluidounce to 1 pint (30 Gm.–480 Cc.) is used as a popular household remedy for its diuretic and diaphoretic effect in febrile states. The dose is ad libitum. Sassafras pith, made into mucilage, is employed as a demulcent in dysentery and inflammations of the air-passages and stomach. The mucilage forms an agreeable and efficient collyrium in acute conjunctivitis, and serves as a vehicle for more active remedies.

Several other plants of the family are elsewhere known as Sassafras, but none of them is so recognized in general commerce. In Venezuela a sassafras oil is collected by boring into an undetermined Lauraceous tree, very much as Copaiba is collected. This oil consists chiefly of apiol. Several trees are said to be known as Queensland sassafras, and there is a Brazilian *Mespilodaphne Sassafras* Meissn.

SCAMMONIUM, *U. S., Br.*—Scammony.

Scammonium Alepense.—*Scammonium*, G.; *Scammonée*, Fr.; *Scammoneo*, It.; *Escamonea*, Sp., Port.

The resinous exudate from the living root of *Convolvulus Scammonium* L. (*Calystegia S.*—Pritz.—Fam. *Convolvulaceæ*).

Scammony is official in most pharmacopœias, several of which add a qualifying adjective equivalent to our term "native," or "virgin," to indicate the natural exudate, in distinction from the extracted resin or other modified product. The British requires that at least 70 per cent. dissolve in ether and that it yield not more than 3 per cent. of ash. Others allow as high as 8 per cent. of ash. The Italian places the ether-soluble portion as high as 75 to 80 per cent., and requires that it dissolve almost completely in 90 per cent. alcohol.

Origin.—Scammony is obtained from a kind of morning-glory plant, native of the Levant. The upper part of the large fleshy root (described below) is exposed and the top sliced off obliquely, when the juice flows into a receptacle, usually a mussel-shell, suitably placed to receive it. The contents are dried, usually imperfectly, to avoid unnecessary reduction of weight, and then massed together, more or less decomposition usually resulting and imparting a peculiar sour odor, usually denominated "cheesy," to the product.

Description.—Scammony is met with in commerce in irregular angular pieces or circular cakes of a greenish dark ash-gray, dark-brown, or nearly black color, of a peculiar sour and somewhat cheese-like odor, and of a slight but distinctly acrid taste; it breaks readily with an angular or splintery fracture, and exhibits in the interior small fissures and cavities and a resinous lustre. It is somewhat translucent in thin fragments. When triturated with water,

it yields a greenish emulsion; its powder has a gray or greenish-gray color. It yields to alcohol or ether not less than 75 (U. S.), and sometimes as much as 95, per cent. of its weight, and when the solvent has been evaporated and the resinous residue dissolved in warm solution of potassium hydroxide, no precipitate is produced on the addition of an acid. The portion left undissolved by alcohol or ether is of a gray color, and is not colored blue by iodine.

Adulteration and Substitution.—Scammony is very commonly and greatly adulterated, the "Smyrna" article being usually regarded as most subject thereto. Such adulteration usually consists of the addition of starch or farinaceous substances, or of earthy matters, recognized by their insolubility in ether. Scammony thus adulterated is frequently smooth externally, dense, heavy, and effervesces when thrown into dilute hydrochloric acid, or its decoction with water yields a blue color on the addition of iodine. One such product, consisting almost wholly of damaged flour or similar material, has received the commercial designation "skillip." The residue left after extraction of the resin has been used as an adulterant, as have also guaiac and other resins. The resin extracted from the dried root has often been substituted. It may be recognized by its peculiar leathery odor.

Montpellier scammony, employed to a limited extent in France, was claimed to be the milk-juice of *Cynanchum monspeliacum* L. (Fam. *Asclepiadaceæ*). The commercial article was found by Laval (1861) to contain from 10 to 21 per cent. of resinous matter, 50 to 59 of starch, and 11 to 18 of earthy substances.

It is said that the resin extracted from the root of *Convolvulus althæoides* L., of the Mediterranean region, has been substituted.

Constituents.—The important constituent of scammony is its glucosidal resin called *scammonin*, which is said to sometimes reach a percentage of 95 of the scammony. Scammonin is soluble in ether. It is elsewhere considered. Almost the entire remaining portion of scammony is gum. Traces of the natural starch of scammony root may exist.

Scammony root, though little used in this country, is official in the B. P. It is the dried root of the above-named plant. It sometimes reaches a yard in length, though usually occurring in short pieces, and is about 5 Cm. (2 In.) thick at the summit, tapering rather gradually to near the end. It is cylindrical, more or less twisted, yellowish-brown, furrowed, and wrinkled externally, whitish, more or less changed to grayish-brown internally; hard and heavy, with a fibrous fracture; bark about one-eighth to one-sixth of the diameter and, like the parenchyma of the meditullium, containing numerous resin-cells; wood-bundles irregularly arranged; odor slight but peculiar; taste sweetish, afterward acrid. The active principle of the root is the same as that of scammony. Starch, gum, and sugar are also contained.

Pharmaceutical Preparation.—Resin of Scammony, U. S. P.

Action and Uses.—Scammony is a drastic hydragogue, slightly cholagogue purge, producing, when administered alone, a good deal of griping. Its action is uncertain, because of its frequent adulteration and its insolubility in the gastro-intestinal contents if they are acid. It is contraindicated if inflammation of the stomach or intestines exist. Large doses may produce severe gastro-enteritis and fatal purgation. Scammony should never be given alone, but in combination with aromatics or other cathartics, which modify its harshness. On account of its tastelessness, it is occasionally given as a purge to children. Scammony is given in the dose of 10 to 20 grains (0.60–1.30 Gm.), the resin in the dose of 3 to 10 grains (0.20–0.60 Gm.), usually in pill form.

SCILLA, *U. S., Br.*—Squill; Squills.

Bulbus scillæ, P. G.—*Scille*, Fr. Cod.; *Squille*, Fr.; *Meerzwiebel*, G.; *Escila, Cebolla albarrana*, Sp.; *Cebola Albarra, Alvarra Branca*, Port.

The bulb of *Urginea maritima* (L.) Baker (*Scilla m.*—L.; *Ornithogalum m.*—Tournef.; *Urginea Scilla* Steinheil.—Fam. *Liliaceæ*), deprived of its dry, membranaceous outer scales, cut into thin slices, and carefully dried, the inner portions being rejected.

Squill is official in all pharmacopœias, many of which caution specifically against a dark-colored, damp, or badly dried article.

Origin.—The squill plant, native of sandy grounds in the Mediterranean basin, is frequently seen cultivated in pharmacists' windows. It produces a large, tunicated, pear-

shaped, greenish bulb, sometimes weighing several pounds, long, flat, leek-like smooth leaves, and a central erect scape about a yard long, terminating in a raceme of greenish-white, 3-merous flowers. Within the bulb the scales may be either white or reddish. The bulb is gathered after the herbage has withered. In its home, it is frequently used fresh, but for our market is prepared according to the above definition. The central portions should be rejected, being the youngest growth and deficient in activity. Being transversely sliced, the segments are then dried in the sun or by artificial heat. Owing to the mucilaginous and hygroscopic nature of the tissue, drying is tedious and difficult, and

FIG. 379.

Scilla maritima L.

FIG. 380.

Squill (Nat.): *a*, inferior central portion.

damage to the drug is very apt to occur in the process. The fresh juice is highly irritating to the skin, often producing an intolerable itching. This is probably due in part to the specific constituents, in part to the raphides. The largest collections are made in the island of Malta.

Description.—In irregular, more or less curved segments, several centimeters (about 1 to 2 In.) long and 4 to 8 Mm. ($\frac{1}{6}$ to $\frac{1}{3}$ In.) broad, thinner in one direction, with 2 to 4 sharp edges; yellowish-white or somewhat reddish, slightly translucent, brittle, and pulverizable when dry, tough and flexible when damp; inodorous and of a mucilaginous, bitter, and acrid taste.

When consisting of very narrow, short, closely curved or coiled segments, from the inner portion of the bulbs (Fig. 380, *a*), it should be rejected.

Microscopical examination reveals very large cells containing well-formed bundles of acicular raphides enveloped in a thick mucilage. The mucilage which fills the non-crystal-bearing cells of the parenchyma is of a different character.

Upon exposure to dampness, squill will absorb from 10 to 15 per cent. of moisture, becoming thus flexible, then drying again. In the powdered state it may thus become converted into a solid, hard mass. These changes are detrimental to its quality.

Constituents.—The important medicinal constituents of squill are glucosides. E. Merck (1879) separated the following three, the last two of which are poisonous; *scillin* (crystalline, pale-yellow, sparingly soluble in water, more freely soluble in alcohol and hot ether, colored by sulphuric acid red-brown, by nitric acid yellow, and on heating green); *scillipicrin* (amorphous, whitish, hygroscopic, and bitter); and *scillitoxin* (amorphous, cinnamon-brown, insoluble in water and ether, soluble in alcohol, colored red and brown by sulphuric acid and orange-red and green by nitric acid). These substances are not regarded as pure chemical bodies, and their relation to *scillein* and *scillain*, isolated by others, are not known. The last, isolated by Kurtz, is probably more nearly free than any other, but it may be merely a purer form of one of the above. It is an amorphous, extremely bitter powder, evidently a glucoside, soluble in water and alcohol, but not in ether. Squill also contains a little volatile oil, about 22 per cent. of sugar, and the peculiar mucilage *sinistrin*, which yields levulose on being boiled with dilute acids. Calcium oxalate exists in large amount.

Pharmaceutical Preparations.—COMPOUND SYRUP OF SQUILL, FLUIDEXTRACT OF SQUILL, SYRUP OF SQUILL, TINCTURE OF SQUILL, VINEGAR OF SQUILL, U. S. P.

Action and Uses.—Squill is largely used for its stimulating, expectorant, and diuretic properties. In poisonous doses it produces violent inflammation of the gastro-intestinal and genito-urinary tracts, manifested by nausea and vomiting, abdominal pain and purging, strangury and bloody urine, and in addition dulness, stupor, convulsions, a marked fall in temperature, an enfeebled circulation, and infrequently death. The employment of squill as an expectorant is largely empirical, as the study of its physiological action does not satisfactorily explain its effect. It appears to stimulate the bronchial mucous membrane and is contraindicated in the presence of fever and acute bronchial inflammation. It may be given with benefit in bronchitis after the subsidence of the acute inflammation, if the sputa are tenacious and raised with difficulty, or if they are very profuse, owing to the lowered tone of the bronchi. In combination with other stimulating expectorants squill is useful, too, in chronic bronchitis. As a diuretic it is frequently employed in dropsy, whether due to chronic disease of the kidneys or to the renal congestion consequent to chronic cardiac disease. It operates not by stimulation of the secreting epithelium of the kidneys, but by toning up, through its irritant action, the depressed condition of these organs. Squill is not to be used if the kidneys are acutely inflamed. In the treatment of cardiac dropsy squill is frequently combined with digitalis. A pill containing 1 grain (0.06 Gm.) each of digitalis, squill, and calomel is popularly known as Niemeyer's pill. The dose of squill in substance is 1 to 5 grains (0.06–0.30 Gm.); of the fluidextract, 1 to 5 minims (0.05–0.30 Cc.). The syrup in the dose of 15 to 60 minims (1–4 Cc.) is the preparation commonly administered in bronchitis.

Other Species.—About 24 species of *Urginea* are recognized, and at least one, *U. Indica* Kunth (*Scilla I.* Roxb.), is used in India in the same way as Squill. It grows in similar localities, has a similar habit, though somewhat smaller, and closely resembles it in every respect. The bulbs of several species of *Scilla* L. (Sect. *Ledebouria*) are there sold as substitutes for it under the name of "Small Squill."

The bulb of *Scilla Peruviana* L. (*Alvarro do Peru*, Port.) has also been exported for use as a substitute for squill.

Many other bulbous plants related to Scilla (*Hyacinthus, Muscari, Narthecium, Gagea,* etc.) are used as diuretics, much like squill, and probably contain related, if not identical, substances.

SCOPARIUS, *U. S.*—Scoparius.

Scoparii cacumina, Br.; *Spartium, Herba scoparii.—Broom, Broom-tops, Irish* or *Scotch broom, Besom*, E.; *Besenginster, Besenkraut, Pfriemenkraut*, G.; *Genêt à balais*, Fr.; *Giesta*, Port.

The dried tops of *Cytisus Scoparius* (L.) Link (*Spartium S.*—L.; *Sarothamnus S.*—Koch; *Genista S.*—Lam.—Fam. *Leguminosæ*).

The Portuguese Pharmacopœia forbids the substitution of *C. grandiflorus* DC.

Origin.—The Broom is a densely growing shrub, usually about 4 or 5 feet high, native of Europe and adjacent Asia, and sparingly naturalized in sandy soil in North America. Its long, slender, erect, and tough branches grow in large, close fascicles, thus rendering it available for broom-making, whence its name.

Description.—Consisting of very long, much-branched, tough, and flexible twigs, which lie parallel with and close to one another, and are about 1 to 2 Mm. ($\frac{1}{25}$ to $\frac{1}{12}$ In.) thick, narrowly 5-winged, with alternating, slight nodes, dark-green and usually naked; internally greenish white; odor peculiar when bruised; taste disagreeably bitter.

The trifoliolate leaves, or the uppermost often reduced to a single leaflet, are sometimes present, as well as the flowers, and occasionally a fruit. The leaflets are sessile, mostly 6 to 12 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ In.) long, and vary from lance-oblong to obovate. The flowers are about 12 Mm. ($\frac{1}{2}$ In.) long, strongly papilionaceous and deep yellow. In Europe, these are considerably employed separately, under the name *Flores genistæ* or *F. scoparii*. Their buds are said to be sometimes employed as a substitute for capers.

The quality of the drug deteriorates with keeping, and this condition can be determined by the partial or complete loss of the peculiar odor of the recently dried drug.

Constituents.—Broom contains two principles, upon one or both of which its activity depends. *Sparteine* ($C_{15}H_{26}N_2$), discovered in 1851 by Stenhouse, of which about 0.03 per cent. is present, is a transparent, oily liquid, colorless when fresh, turning brown on exposure, of an aniline-like odor and a very bitter taste. It may be obtained by extracting the drug with acidulated water, concentrating the infusion, and distilling after addi-

tion of an excess of sodium hydroxide as long as the distillate shows an alkaline reaction. For the purpose of purification the distillate is neutralized with hydrochloric acid, the solution evaporated, and the residue decomposed by means of solid potassium hydroxide, and distilled. Sparteine is heavier than water, and boils at 288° C. (550° F., Hager), 311° C. (593.8° F., Brühl). It is but slightly soluble in water, but readily so in alcohol, ether, and chloroform, and is insoluble in benzene and benzin. Sparteine is a diacid base, and its solutions show strongly alkaline reaction. It imparts to the drug its cardiant properties. Its sulphate is separately considered. *Scoparin* ($C_{21}H_{22}O_{10}$) is a glucoside occurring in pale-yellow crystals, odorless and tasteless, soluble in alcohol and hot water. It yields a green-yellow precipitate with lead acetates and yields picric acid when treated with nitric acid. It probably represents most of the direct diuretic activity of broom.

FIG. 381.

Scoparius: *a*, branch (reduced); *b*, twig (Nat.); *c*, cross-section (× 2).

Pharmaceutical Preparation.—INFUSION OF BROOM, B. P.

Action and Uses.—Although scoparius and sparteine were formerly highly esteemed as stimulants to and regulators of the heart, their infrequent employment to-day in cardiac disease perhaps best expresses the opinion of the medical profession as to their value. Careful investigations, both clinical and experimental, by many observers, have elicited opposing views of the exact mode of action of scoparius upon the nervous and circulatory systems. Without specifying what part of the nervous apparatus is affected by the drug, it is certain that its action is depressant and that in overdose it probably kills by paralyzing the respiratory centres. Upon the circulation sparteine produces a transient rise in arterial pressure, followed by a longer period of decreased vascular tension. The contention of some investigators that it is a cardiac stimulant, and of others of equal reputation that it is depressant demonstrates that more extensive study of the action of the drug upon the heart is necessary for final decision. Small doses first slow the heart for a short period of time and then hasten its rate and at the same time increase the volume of the pulse. Large doses distinctly depress the heart muscle and pneumogastric nerves. Its effect upon the heart begins to be manifested in from 20 to 30 minutes after its administration and persists for 6 or 8 hours. It has no cumulative action. Those who advocate its employment claim that it is a useful heart tonic and regulator in the incompetency of chronic valvular disease and in cardiac arrythmia from any cause. The efficiency of scoparius as a diuretic is conceded by all, and is probably dependent upon the contained scoparia, whose action upon the renal epithelium is similar to that of buchu and uva ursi. It is employed in dropsy, either that of cardiac disease or of chronic parenchymatous nephritis, but is contraindicated in the presence of acute renal inflammation. For its diuretic action scoparius is given in decoction made by adding ½ ounce (16 Gm.) to 1 pint (480 Cc.) of water and boiling down to ½ pint (240 Cc.); and of this 1 ounce (30 Cc.) should be taken every 3 hours. The dose of the fluid-extract is 15 to 30 minims (1–2 Cc.). The dose of sparteine is variable. Some claim to obtain results from as little as $\frac{1}{20}$ grain (0.003 Gm.), while others recommend that it be given in 2- to 4-grain (0.12–0.25 Gm.) doses. It is probably best to begin with a small dose, $\frac{1}{10}$ grain (0.006 Gm.), and rapidly increase the dose until some effect is noted.

Allied Drugs.—*Spanish broom* is *Spartium junceum* L. (*Spartianthus j.*—Link; *Genista Hispanica* Lam.), a near relative of the last, native of the Mediterranean region, and commonly naturalized in subtropical America. Its branches are much stouter and are nearly terete, and its leaves are pubescent underneath. Its properties are similar to those of Scoparius.

Coronilla is the herbage of various species of the genus of that name, natives of Europe, and some naturalized in North America. The drug (at least that from *C. scorpioides* Koch) contains the glucoside *coronillin* ($C_7H_{12}O_5$), a yellow powder soluble in water and alcohol, but very little in ether and chloroform. The action and uses of the drug are very similar to those of broom.

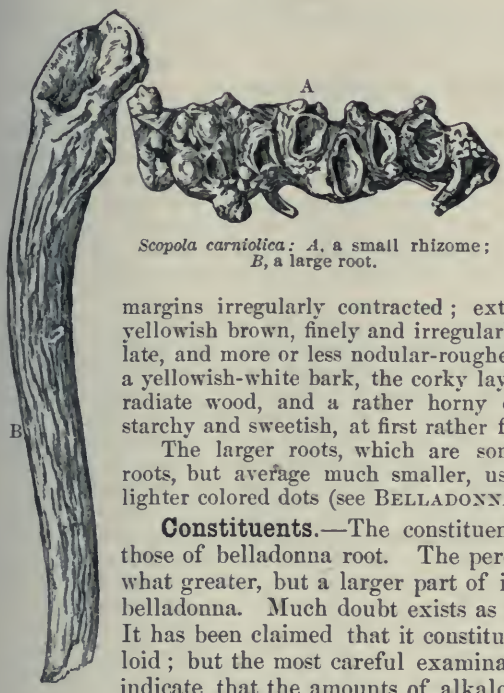
SCOPOLA, *U. S.*—Scopola.

Belladonna Scopola, Scopola Belladonna, Japanese Belladonna (incorrectly).

The dried rhizome and larger roots of *Scopola carniolica* Jacq. (*Hyoscyamus Scopolia* L.; *S. trichotoma* Moench; *S. atropoides* Link.—Fam. *Solanaceæ*).

Origin.—The plant is a European perennial herb, especially abundant in Austria. It grows chiefly in rocky ground, and somewhat resembles belladonna, though much smaller. The rhizome is very largely collected to be used as a substitute for belladonna root, and the leaves are added, as an adulterant, to belladonna leaves.

Fig. 382.



Scopola carniolica: *A*, a small rhizome; *B*, a large root.

Description.—Rhizome of horizontal growth, more or less curved and shortly and sharply flexuose, cylindrical or slightly vertically flattened; occurring mostly in pieces from 2.5 to 7.5 Cm. (1 to 3 In.) long, and 0.8 to 1.6 Cm. ($\frac{1}{3}$ to $\frac{2}{3}$ In.) broad, often split before drying; upper surface marked by large, closely set, cup-shaped stem-scars, their margins irregularly contracted; externally varying from dark brown gray to yellowish brown, finely and irregularly longitudinally wrinkled, obscurely annulate, and more or less nodular-roughened; fracture short and sharp, exhibiting a yellowish-white bark, the corky layer dark brown, a light brown, indistinctly radiate wood, and a rather horny central pith; odor slight, peculiar; taste starchy and sweetish, at first rather faint, afterward acrid.

The larger roots, which are sometimes present, are similar to belladonna roots, but average much smaller, usually of a browner color, and marked by lighter colored dots (see Belladonna).

Constituents.—The constituents of Scopola are almost identical with those of belladonna root. The percentage of total alkaloid is usually somewhat greater, but a larger part of it is usually hyoscyamine than of that of belladonna. Much doubt exists as to the extent to which scopolamine exists. It has been claimed that it constitutes as much as a tenth of the total alkaloid; but the most careful examinations which we know to have been made indicate that the amounts of alkaloids other than atropine and hyoscyamine are much smaller than has been supposed.

The Pharmacopœia requires that scopola shall yield not less than 0.5 per cent. of its alkaloids, when assayed by the process given for belladonna leaves and root (see p. 286), and using 10 Gm. of scopola in No. 60 powder.

Pharmaceutical Preparations.—Extract of Scopola, Fluidextract of Scopola, U. S. P.

Action and Uses.—The sedative action of scopola depends upon the presence of the alkaloid scopolamine, which is identical with hyoscine (see Hyoscine Hydrobromide). It is given as a hypnotic in the insomnia due to mania, hysteria, and delirium tremens. It is of service in some cases of spermatorrhœa and nocturnal emissions caused by irritation of the spinal centres. Scopola is given in the dose of 1 to 3 grains (0.05–0.15), the fluidextract in the dose of 1 to 3 minims (0.05–0.15), and the extract in the dose of $\frac{1}{4}$ to $\frac{1}{2}$ grains (0.016–0.03).

S. Japonica Maxim., of Japan, yields the true *Japanese belladonna*, which the Japanese Pharmacopœia permits to be used as a substitute for belladonna root whenever the latter is prescribed. This plant is so like that of *S. carniolica* that botanists have the gravest doubts as to their being distinct species. The only observable difference in the rhizomes is the somewhat larger size of the Japanese, and a slight difference in the prominence of the vascular bundles. The constituents appear identical. 4 or 5 species of Scopola are recognized.

SCOPOLAMINÆ HYDROBROMIDUM, *U. S.*—Scopolamine Hydrobromide.

Scopolaminum hydrobromicum, P. G.; *Hyoscinæ hydrobromidum*, Br.; *Bromhydrate d'hyoscine*, Fr.; *Hyoscine hydrobromide*, E.; *Skopolaminhydrobromid*, G.

Formula, $C_{17}H_{21}NO_4.HBr + 3H_2O$. Molecular weight, 434.92.

The hydrobromide of an alkaloid obtained from scopola and other plants of the Solanaceæ; chemically identical with hyoscine hydrobromide.—U. S.

(This salt has been fully described under Hyoscinæ Hydrobromidum, which see on p. 795.)

Action and Uses.—The physiological action, therapeutical application, and dose of scopolamine hydrobromide are identical with those of hyoscine hydrobromide (which see).

SCROPHULARIACEÆ.—Figwort Family.

A family of nearly 200 genera and about 2500 species, occurring mostly in temperate and subtropical regions, and many of them producing flowers of great beauty, on which account they are frequently cultivated. Unlike the Labiatæ, to which they are rather closely related, these plants seldom contain much volatile oil, though resinous substances are common. The most important constituents are glucosides, and many of them are poisonous, or powerfully active. Elsewhere we have considered the important drugs DIGITALIS and LEPTANDRA. Minor drugs worthy of consideration here are Verbascum, Scrophularia, Chelone, Gratiola, Euphrasia, and Linaria.

Verbascum or *Mullein* (*Wollkraut*, *Königskerze*, G.; *Bouillon-blanc*, *Molène*, Fr. Cod.; *Gordoloba*, Sp.) is usually understood as the leaves (*Folia verbasci*) of *V. Thapsus* L. (*V. Schraderi* G. Meyer; *Thapsus s.*—Opiz), native of Europe and Asia, and exceedingly abundant as a naturalized weed in the eastern United States. The plant has a great variety of common names (*Great*, *Velvet*, or *Common mullein*, *Mullein dock*, *Blanket-leaf*, *Flannel leaf*, *Feltwort*, *Adam's blanket*, *Velvet-plant*, *etc.*). It is a very stout, woolly perennial, bearing a radical rosette of leaves often 1 to 2 feet long, and successively smaller ones upward upon the stem, which is simple, may reach a height of 6 or 8 feet, is winged by the strongly decurrent leaves, and terminates in a long, thick spike of flowers. The leaves are mostly oblong, but vary to lance-oblong and obovate, the summit broad but acutish, entire, very thick and densely and softly tomentose. They are nearly odorless, and of a mucilaginous and bitterish taste. They contain gum as their principal constituent, together with 1 to 2 per cent. of resin, divisible into two parts, one soluble in ether, the other not, a readily soluble amaroid, a little tannin, and a trace of volatile oil.

The flowers (*Flores verbasci*) are also considerably employed. The part used is the sulphur-yellow corolla, which is rotate, about 2.5 to 3.7 Cm. (1–1½ In.) broad, tomentose on the back, and bears in its throat 5 stamens, the 3 upper with reniform, the 2 lower with elongated anthers. These flowers contain gum, resin, coloring-matter, glucoside, and yield a small amount of volatile oil.

More than a dozen other species of Verbascum are employed medicinally. *V. phlomoides* L., of Europe, and *V. pulverulentum* Vill., of Madeira, are used as tænicides and fish poisons.

Gratiola, *Herba gratiolæ* or *Hedge-hyssop* (*Herb-of-grace*, E.; *Gnadenkraut*, *Gottesgnadenkraut*, *Wildauran*, G.; *Gratiole*, Fr.; *Graciola*, Sp.) is the dried herb of *G. officinalis* L., though the rhizome is sometimes used separately. The stem grows from a creeping scaly rhizome to the height of 15 to 30 Cm. (6–12 In.), has opposite, sessile, lanceolate, finely serrate, 3-nerved, smooth, pale-green leaves, and solitary axillary whitish or reddish 2-lipped flowers, with yellow hairs in the tube. The plant is inodorous and has a very bitter somewhat acrid taste. Its active constituent is the bitter, crystalline glucoside *gratiolin* ($C_{25}H_{40}O_5$), which splits under the influence of acids into sugar, amorphous *gratiolaretin*, and scaly *gratioletin*. Walz also isolated the reddish amorphous bitter principle *gratiosolin*, which is soluble in water and alcohol, and is likewise a glucoside. *Gratioloic acid* crystallizes in white scales of a fatty odor. A half dozen other species are employed.

Chelone or *Balmony* (*Snakehead*, *Turtlehead*, *Shellflower*, *Fish-mouth*, *Bitter-herb*, etc., E.; *Chelone*, G., Fr.) is the dried herb *Chelone glabra* L. It is a perennial, smooth herb of swamps, lake- and river-sides throughout eastern North America. It reaches a height of 2 to 4 feet, branches sparingly, the stems slender, the leaves opposite, nearly sessile, lance-oblong, pointed, sharply serrate, shining, the white or purplish flowers in a short, dense terminal spike, the corolla inflated, obovoid, 2-lipped, the mouth slightly open, which appearance gives it its common names. The lower lip is bearded in the throat and the 4 filaments and heart-shaped anthers are woolly. The odor is slight, the taste markedly bitter. The bitter principle is soluble in alcohol and water, but its value is unknown. There is a little gallic acid. Several other species are employed.

Scrophularia, *Figwort*, or *Scrofula plant* (*Square-stalk*, *Carpenter's-square*, *Kernel-wort*, *Pile-wort*, *Throat-wort*, etc., E.; *Kropfwurz*, *Knotenwurz*, G.; *Scrophulaire*, Fr. Cod.; *Escrofularia*, Sp.) is the leaves and flowering tops, also the rhizome and roots, of *S. nodosa* L., a European perennial, smooth herb. The American plants long referred to this species are now known to comprise several distinct species. The plant has a horizontal branching fleshy rhizome, to which numerous oblong or oval tubers of the thickness of the thumb are attached. The leaves are opposite, petiolate, ovate-oblong, rounded or heart-shaped at the base, and cut-serrate on the margin. The flowers are in a terminal loose panicle, have a greenish-brown, tubular-globose, 5-lobed corolla with 4 stamens, and produce a 2-celled many-seeded capsule. The fresh plant, bruised, has an unpleasant odor and a nauseous, bitter, and acrid taste; on drying it loses about 75 per cent. in weight and becomes nearly inodorous. Our information as to the constituents is very contradictory, owing doubtless to the materials examined having pertained to different species. A strongly bitter principle in the root has been called an alkaloid, but is said not to be present in the herb. A peppery resin, tannin, gum, etc., also exist.

Euphrasia or *Eye-bright* (*Euphrasy*, *Eye-wort*, E.; *Augentrost*, G.; *Euphraise*, Fr.; *Eufrasia*, Sp.) is the herb *E. officinalis* L., of Europe. This is a tender little annual, about 6 inches high, growing in damp places, almost throughout Europe, and represented by very similar species in America. It has opposite, shortly petiolate or sessile, ovate or lanceolate leaves, which are about 8 Mm. (⅓ In.) long, and have 4 or 5 teeth on each side; the upper (floral) leaves are alternate, nearly rhomboid, and bristly-toothed. The axillary flowers have a 4-cleft calyx and a white or lilac 2-lipped corolla with a yellow throat, 4 ascending stamens, and an oblong, many-ovuled ovary. When fresh, the plant has a faint balsamic odor which is almost completely lost on drying; the taste is somewhat saline, bitter, and scarcely astringent. The constituents of Eye-bright are very little known. Guz found the recent plant to contain 62 per cent. of moisture and 10.8 per cent. of cellulose, the remainder being tannin, a little volatile oil, an acrid and bitter principle, several organic acids, mannit, glucose, and other common principles. The tannin precipitates ferric salts dark-green, and lead salts of a bright-green color.

Veronica or *Speedwell* (*Paul's betony*, *Fluellen*, E.; *Ehrenpreis*, G.; *Véronique mâle*, Fr.; *Veronica*, Sp.) is the dried herb of *V. officinalis* L., a slender, creeping hairy perennial herb, native of the Old World, but abundantly naturalized in the eastern United States, where it grows in open, grassy places. The leaves are opposite, short-petioled, about 2.5 Cm. (1 In.) long, elliptical-obovate, crenate-serrate. The flowers are in 1 or 2 axillary racemes on the upper part of the branches, are on short pedicels, and have a wheel-shaped 4-parted pale-blue corolla with dark-blue stripes and 2 exserted stamens. The fruit is an inversely heart-shaped 2-celled capsule. The fresh herb is faintly aromatic; after drying it is inodorous and has a bitterish and slightly astringent taste. Speedwell contains an alkaloid, a saponin-like body, a little tannin, resin, etc.

There are nearly 200 species in the genus Veronica, some 20 of which have been employed as drugs. *V. Beccabunga* L. is the European *Brooklime* (*Bachbungen*, G.; *Beccabunga*, *Cressonée*, Fr.), which grows in and about running water. It has an ascending smooth stem, with opposite, short-petioled, oval-oblong, crenate-serrate, obtuse, smooth leaves about 3.8 Cm. (1½ In.) long, and bears loose axillary racemes of pale-blue and veined flowers. It is used in the fresh state, and is bitter, somewhat saline, and pungent. In Asia Minor the root of *V. peduncularis* Bieb. (*V. nigricans* Koch) is used under the name *Batitjoe*.

Linaria or *Toad-flax* (*Herba linariæ.—Snap-dragon*, *Butter-and-eggs*, *Ramstead*, *Whin*, E;. *Leinkraut*, *Flachskraut*, *Löwenmaul*, G.; *Linaire commune*, Fr.: *Linaria*, Sp.) is the plant *Linaria Linaria* (L.) Karsten (*Antirrhinum L.*—L.; *L. vulgaris* Miller), a rather handsome-flowering perennial herb of Europe, and very abundant along roadsides, in fence-rows, and other waste places in the eastern United States. It is 30 to 45 Cm. (1–1½ Ft.) high, has alternate, sessile, lance-linear, almost 3-nerved, smooth, and light-green leaves, 25 to 38 Mm. (1–1½ In.) long; and terminal racemes of showy yellow flowers, which have a personate corolla, continued at the base into a curved spur of the same length. When fresh the herb has a slight disagreeable odor and a bitterish somewhat acrid taste. Linaria contains the crystalline amaroid *linariin*, an acrid resin, tannin, volatile oil, and volatile *antirrhinic acid*.

Curanga amara Juss. (*Herpestis a.*—Benth.; *Gratiola a.*—Roxb.) yields the important East Indian tonic and febrifuge *Curanja* or *Koen-tao-tjao*. It contains the bitter, alcohol-soluble glucoside *curanjiin* ($C_{48}H_{77}O_{20}$).

The tropical American herb *Vandellia diffusa* L. is used like Gratiola. The dried plant has a strong odor of tobacco. *Bonnaya rotundifolia* Benth. is the East Indian *Tsjanga-puspam*, used as an antispasmodic. *Scoparia dulcis* L., a common weed of tropical America, is used as an astringent and antispasmodic under the name *Vaçourinha*. More than a hundred other species of the family are in medicinal use, nearly all of them containing bitter substances, and many possessing anthelmintic properties.

SCUTELLARIA, *U. S.*—Scutellaria.

Hoodwort, Madweed, Mad-dog or *Side-flowering skullcap, Blue pimpernel, Hooded willow-herb*, E.; *Helmkraut, Schildkraut*, G.; *Scutellaire*, Fr.

The dried plant *Scutellaria lateriflora* L. (Fam. *Labiatæ*).

Origin.—This pretty little plant is common on rocky banks of lakes and streams, in the edges of marshes and other damp and partly shaded localities, almost throughout North America, except in the far north. It blossoms in middle and late summer. It should be gathered when in full bloom and carefully dried in the shade.

FIG. 383.

Scutellaria lateriflora (½ Nat.).

FIG. 384.

Scutellaria canescens (½ Nat.).

Description.—Dark-green, smooth, or slightly puberulent on the younger portions, the branches elongated, slender, sharply quadrangular; leaves opposite, exstipulate, shortly petioled, the blades rarely exceeding 8 Cm. (3 In.) long and about a third as broad, ovate, rounded or truncate at the base, acuminate, obtusish or acutish, shortly and obtusely serrate, thin, veiny; flowers in axillary, peduncled, mostly simple and secund racemes, nearly sessile, about 6 Mm. (¼ In.) long, the calyx bilabiate, in fruit becoming closed and developing a large helmet-shaped crest, the corolla deep-blue, bilabiate, the stamens didynamous; fruit of 4 depressed-globose papillose nutlets 0.5 to 1.25 Mm. ($\frac{1}{50}$—$\frac{1}{20}$ In.) broad.

So-called "Western Scutellaria," more or less rough gray-hairy and with much larger flowers, in terminal panicles, is not of this species. It is probably derived from different species, but that which we have examined is *S. canescens* Nutt.

Constituents.—Scutellaria contains, as its most important principle, a bitter, crystalline glucoside, which may or may not be identical with that of the European species *S. altissima* L. or of the Japanese species *S. Baicalensis* Georgi (*S. lanceolaria* Miq.), both of which have been called *scutellarin*. Molisch and Goldschmeidt give to that from the last-named plant the formula $C_{21}H_{20}O_{12}$ and name its derivative *scutellarein*. The volatile oil of skull-cap, unlike those of most members of the family, is small in amount and apparently unimportant. Tannin is apparently present, though its presence has been denied by those who have examined the plant chemically. The genus contains about

100 species, and quite a number have been employed. Lloyd gives *S. versicolor* Nutt. as one of the important substitutes for skull-cap.

Pharmaceutical Preparation.—Fluidextract of Scutellaria, U. S. P.

Action and Uses.—Scutellaria is devoid of properties which entitle it to be classed among official drugs. It has been recommended in a variety of diseases, viz., epilepsy, chorea, nervous exhaustion, intermittent fever, incontinence of urine, etc. Its dose is 1 to 2 drachms (4–8 Gm.), given in decoction or fluidextract.

SENEGA, *U. S.*—Senega.

Senegæ radix, Br.; *Radix senegæ*, G.; *Radix polygalæ Virginianæ.*—*Senega* or *Seneca root* or *snakeroot*, *Rattlesnake root*, *Mountain flax*, E.; *Senegawurzel*, G.; *Polygala de Virginie*, Fr.; *P. de Virginia*, Port.; *Poligala de V.* Sp.; *Poligala Virginiana*, It.

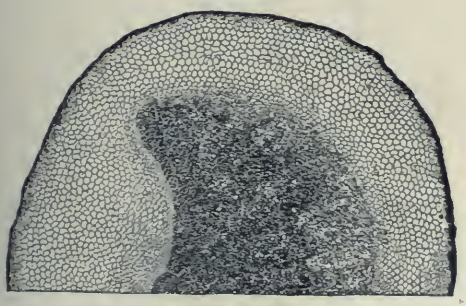
The dried root of *Polygala Senega* L. (Fam. *Polygalaceæ*).

Senega is official in all pharmacopœias. The Swiss requires that if the filtrate from its maceration in ether have the ether removed with warm water, ferric chloride will impart a violet color to the residue, and that the ethereal extraction of 10 Gm. should leave, on evaporation, at least 1.4 Gm. of fat and resin.

Origin.—The Senega plant is a perennial herb of eastern and central North America, as far south as North Carolina. The root sends up a cluster of erect, slender, simple, or little branched stems about a foot in height. The leaves are alternate, sessile, lanceolate or oblong-lanceolate, rough on the margin, otherwise smooth, and narrowed to both ends. The flowers are nearly sessile, in slender terminal spikes, and have 5 sepals, of which the 2 lateral ones are round, petaloid, and rose-colored; the 3 petals are whitish. Senega flowers in May and June, and ripens its small 2-celled and 2-seeded capsule in July. The large, broad-leaved form, growing mostly in the north-central States, has been called *var. latifolia* T. et G. The root should be collected in the autumn. Our principal supply now comes from Minnesota and northward.

Description.—Mostly 7 to 15 Cm. (3 to 6 In.) long and 4 to 8 Mm. ($\frac{1}{6}$ to $\frac{1}{3}$ In.) thick, exclusive of the large, knotty, many-headed crown, occasionally reaching several times this size; tortuous, tapering, and bearing several similar horizontal branches, and a few rootlets, and for a variable distance below the crown a more or less sharp keel, varying greatly in prominence, and usually taking a spiral direction, often nearly absent; externally yellow-brown to dark-gray-brown, longitudinally wrinkled; fracture rather tough, but short and sharp, the bark thick, yellow or brownish, of a waxy or resinous, faintly fine-radiate appearance, enclosing a yellowish-white wood, from which a larger or smaller radial segment is usually wanting; odor slight, disagreeable; taste sweetish, then acrid; starch is wanting.

Fig. 385.



Senega root: section showing one-sided growth of wood and inner bark (× 18).

Fig. 386.

Transverse sections of Senega root.

Senega often exhales a slight odor of oil of wintergreen. We have found the same odor strong in growing plants of other species of Polygala.

Of commercial senega, several geographical varieties are recognized, all presenting minor differences in their appearance. Southern senega is smaller and usually paler. Manitoba senega is very large and stout, often dark-colored and with purple discolorations about the crown.

Adulteration.—Senega has been much subjected to adulteration. *Triosteum root*, and all other adulterants, excepting other species of Polygala, are readily recognized by the presence in them of starch. Several other species of Polygala have been thus used. "White" or "Texas" Senega is said to be derived from *P. Boykinii* Nutt., of the Southern States; but all that we have encountered in the market was from *P. alba*. The

Fig. 387.

False Senega: transverse section (× 10).

latter averages smaller than the genuine, is paler, and is (at least usually) wanting in the keel. Various other species have been mentioned in this connection, but the roots of all are apparently too small to prove deceptive.

Constituents.—The acrid constituents of Senega are about 5 or 6 per cent. of a saponin-like mixture which is divisible into *polygalic acid* (about three-fourths of the

Fig. 388.

Manitoba Senega: a small root (¾ Nat.).

Fig. 389.

Polygala alba: a large root (¾ Nat.).

whole) and *senegin*, the two bearing much the same relations as quillajic acid and quillajasopotoxin of quillaja bark. Senegin is precipitated by basic lead acetate, polygalic acid by both the neutral and basic substances and also by ammonium sulphate. Neither starch nor tannin is present, but there is a very small amount of methyl-salicylate, also resin, fat, sugars, etc. The ash should not exceed 7 per cent. The methyl-salicylate seems to be a decomposition-product, increasing as the drug is kept. When Senega is confined closely for a long time, this odor may become very strong.

Pharmaceutical Preparations.—Infusion of Senega, B. P.; Fluidextract of Senega, Syrup of Senega, U. S. P.

Action and Uses.—The study of the action of senega, or its active principle senegin, fails to establish a rational basis for its employment as a stimulating expectorant and diuretic. It is used in acute bronchitis after the subsidence of the early inflammation,

when the mucus is scanty and tenacious and a stimulating expectorant is indicated. In a like manner if given in spasmodic croup it does more good after the stage of spasm, when the condition is that of a simple catarrhal laryngitis. It is useful in chronic bronchitis with bronchorrhœa. Its diuretic effect is neither pronounced nor certain and is of no avail as a remedy in dropsy. The dose of senega in substance is from 10 to 20 grains (0.60–1.30 Gm.), of the fluidextract from 10 to 20 minims (0.60–1.30 Cc.). The syrup is given in the dose of ½ to 2 drachms (2–8 Cc.).

Allied Products.—The genus *Polygala* contains nearly 500 species, many of them, in the tropics, being shrubs, and some, of great beauty, cultivated for ornament. Some 40 have been recorded as used medicinally, most of them like Senega, and, so far as known, because of similar constituents.

The drug *Polygala*, as commonly understood (*Bitter Polygala*, E.; *Kreuzblume*, *Milchwürz*, G.: *Polygala*, *Laitier*, Fr.; *Polygala amarga*, Sp.), is the herb, or more especially the root, of *P. polygama* Walt. (including *P. rubella* Muhl.). It is a biennial herb growing in dry fields and pastures from Canada southward to the Gulf of Mexico. It has a fusiform root and numerous glabrous nearly simple stems which are 15–20 Cm. (6 to 8 In.) high, and bear a terminal narrow raceme of about 15 to 25 purple, finally pendulous flowers. The leaves are alternate, linear-oblong or oblanceolate, narrowed below, obtuse, and somewhat mucronate. The flowers are showy and conspicuously crested. Racemes of inconspicuous flowers are produced on procumbent stems, and usually are fertilized in the bud. The plant is without odor and has a bitter taste.

P. Siberica L. yields the Chinese drug *Yuen-chi*, the root used in cataplasms. *P. angulata* DC. (*P. Poaya* Mart.) is the Brazilian *Poaya do Campo*, used like ipecac. *P. glandulosa* Kunth is the Chinese *Yan-foo*. *P. thesioides* Willd. and *P. grindioides* Willd., of Chili, are much used diuretics, under the names *Chinchin* and *Quelenquelen*. A number of East Indian species are used as expectorants, *P. Chinensis* L. being used under the names *Merádú* and *Negli*. *P. theœzans* L., of Java and Japan, is used as a tea-substitute, and *P. venenosa* Juss., *Katu-tutun*, and several others are very poisonous. The seed of *P. Javana* DC. is a tænicide. In the Soudan, *P. micrantha* Guill. et Per. is used as a purgative.

P. butyracea yields to the African natives an oil-seed from which they extract the butter-like fat *Malonkang* or *Ankalaki*, used as a food. Its composition is olein 30.5 per cent., palmitin 57.54, myristin 6.16, and free palmitic acid 4.799 per cent.

SENNA, *U. S.*—Senna.

Folia sennæ, P. G.; *Senna Alexandrina* and *S. Indica*, Br.; *Folia Cassiarum*, Nor. —*Senna-leaves*, E.; *Sennesblätter*, G.; *Feuilles de sêné*, Fr.; *Sena*, It.; *Sen*, Sp.; *Senna*, Port.

The dried leaflets of *Cassia acutifolia* Delile (*C. Senna* L. [in part]; *C. lanceolata* Nect.; *C. orientalis* Pers.; *C. lenitiva* Bisch.; *Senna acutifolia* Link), the *Alexandria* variety, or of *C. angustifolia* Vahl. (*C. elongata* Lem.; *C. lanceolata* W. et A.; *C. acutifolia* Nees; *C. medica* Forsk.; *C. medicinalis* Bisch.; *Senna officinalis* Roxb.; *S. angustifolia* Batka), the *Indian* or *Tinnevelly* variety (Fam. *Leguminosæ*).

Senna is official in all pharmacopœias, both varieties being in nearly all cases named. The German recognizes only the Indian, and the Danish gives the same preference. Many use for the Alexandrian variety the synonym "C. lenitiva." The Italian, Spanish, and Portuguese name *C. obovata* Coll., once official in the B. P. A number authorize the deresinating of senna by extraction with 90 per cent. alcohol and drying. Most refer to *Argel leaves*, from *Solenostemma Argel* (Delile) Hayne (*Cynanchum A.*—Del.; *C. oleifolium* Nect.; *C. fruticosa* R. Br.—Fam. *Asclepiadaceæ*), either entirely excluding them or fixing a limit (up to 10 per cent.). Such a mixture is called *Sen de la Palta* by the Spanish. Some exclude Coriaria leaves (see *Adulterants*).

Origin.—The senna plants are small, soft-wooded shrubs, with unequally pinnate leaves, which are commonly collected entire, the leaflets being separated after drying. A part of the Alexandrian variety is collected by cutting down the entire plant. In all cases the crude product is more or less admixed with sticks, stalks, flowers, pods, other leaves, dust and dirt, and even stones. The larger impurities are removed by hand, the finer ones by sifting. By sifting, also, broken leaves are removed, and the entire ones are separated into several sizes, the larger being respectively higher priced, though not at all superior. These processes still leave remaining any spurious, diseased or discolored leaves, so that hand-picking alone produces a perfect article. Alexandria senna is quite widely distributed through central Africa, but is collected chiefly in the

country about the middle and upper Nile River, and the crop is mostly accumulated in Suakim and Cairo. India senna is native of Arabia. Some of this wild product is collected and marketed as *Mecca* or *Arabian senna*, but the genuine commercial article is the product of plants cultivated in British India, and is very carefully gathered, selected, and prepared. The Mecca senna, here referred to, is occasionally marketed as *Bombay senna*, the genuine Bombay senna being a small and poor grade of the cultivated India senna.

Description.—Alexandria senna consists of leaflets with extremely short, stout petiolules, about 2.5 Cm. (1 In.) long and 1 Cm. ($\frac{2}{5}$ In.) broad, inequilaterally lanceolate or lance-ovate, acutely cuspidate, entire, sub-coriaceous, brittle, pale green, or slightly yellowish or grayish green, sparsely and obscurely hairy, more so underneath, the hairs appressed; odor peculiar, tea-like; taste mucilaginous, tea-like, bitterish.

It is frequently contaminated with the one-nerved, thick, wrinkled, glaucous, equilateral Argel leaves.

India senna leaflets average nearly twice as long, though but little broader, are more abruptly pointed, usually more yellowish, and the hairiness is even more obscure.

FIG. 390.

Tinnivelly senna.

FIG. 391.

Alexandria senna.

FIG. 392.

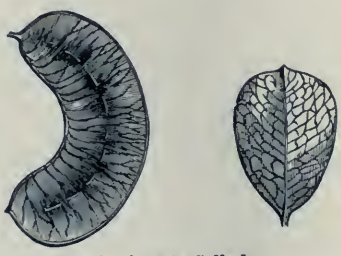
Tripoli senna: leaflets and legumes.

The leaflets of India senna vary considerably in their relative thinness, breadth, and acumination, and various attempts have been made to distinguish forms or varieties; but the differences appear to be insignificant.

The powder shows rosettes of crystals and single rhomboidal crystals, and the peculiar thick-walled, one-celled epidermal hairs are characteristic. In that of Alexandria senna the hairs are 2 or 3 times as numerous as in the Indian. A larger portion of the hairs of the Indian are curved than those of the Alexandrian.

Inferior Products, Substitutes, Adulterants, etc.—A long list of adulterants of senna in the entire condition has been recorded, and the effect has been to create an

FIG. 393.



Cassia obovata Colladon.

FIG. 394.

Solenostemma argel Hayne.

exaggerated idea of the extent to which adulteration is practiced. The retention of diseased, discolored or musty leaves through imperfect cleaning is common in the poorer grades of Alexandria senna, such as the "Tripoli senna," and constitutes the principal defect found in this drug. Small and broken leaflets of India senna are often sold for Alexandria senna, or mixed with that variety. The presence of Argel leaves

(see above) is also very common. These leaves are thick, have a heavy midrib, but indistinct, pinnate veins, a wrinkled surface, an equal base, and their hairs are three-celled and thin-walled. They occur far less commonly than in former times. *Cassia oborata* (*Senna baladi* of the Arabians), being still official in some countries, are naturally apt to be offered. They are easily distinguished by their obovate form, with narrowed base, and the cells of the lower epidermis are pappillose. Holmes has tested the *Aden senna*, from *C. holosericea* Fres., offered as a substitute, and found it efficient. These leaflets are smaller, relatively broader, less acute, and more hairy. Coriaria leaves, or *Curriers' sumac* (*Gerberstrauch*, G.; *Redoul, Sumac des corroyenes*, Fr.), the leaves of *Coriaria myrtifolia* L. (Fam. *Coriariaceæ*), formerly common, now rare, constitute a serious danger, since they are poisonous. They are thickish and distinctly 3-nerved, bitter, strongly astringent, and somewhat acrid. They contain tannin and the glucoside *coriamyrtin* ($C_{30}H_{36}O_{10}$), which occurs in prisms, melting at 220° C. (428° F.) and soluble in water, alcohol, and ether. It is an irritant and convulsant poison, resembling picrotoxin in action. Other species are also poisonous, one or more yielding the New Zealand *foot-poison*. The fruits, consisting of (usually 5) blackish, obliquely ovoid nutlets surrounded by scales, have been mistaken for blackberries, with poisonous results. *Cracca* (*Tiphrosia*) leaflets, here figured, and also somewhat poisonous, have also been found in senna.

Constituents.—The active constituents of senna have been shown, chiefly by Tschirch, to be partly, at least, very close relatives of those of ALOES, RHAMNUS, and RHEUM—namely, one or more glucosides of the *oxymethylanthraquinone* group, yielding emodin. Although it has not been shown, nor is it probable, that these substances are capable of producing the same, nor equally desirable purgative effects as a preparation of senna, yet they are probably the most important factor in the result. Tschirch described *anthraglucosennin*, the emodin ("senna-emodin") from it melting at 223° C. (433.4° F.), and its chrysophanic acid ("senna-chrysophanic acid") melting at 171° to 172° C. (339.8°–341.6° F.). Under the action of alkalies, anthraglucosennin yielded senna-nigrin ("sennigrin"), an amorphous blackish body which also yielded emodin and chrysophanic acid. An *isoemodin* was extracted, but its source was not established; also a *rhamnotin* and the yellow glucoside *glucosennin*. The percentage of emodin obtained ranged from 0.8 per cent. (in Tinnevelly) to 1 per cent. (in good Alexandrian), and was only 0.6 per cent. from deresinated senna. The extractive substance "cathartic acid," elsewhere described, is yielded abundantly by senna. Tschirch's method of obtaining the above substances was as follows: The anthraglucosennin is obtained by percolating the senna with water rendered slightly ammoniacal. It is then extracted with ether, this extract is boiled in toluene, and the solution poured into petroleum spirit, when the emodin is precipitated. Isoemodin remains undissolved by the ether. Glucosennin ($C_{22}H_{18}O_8$) remains in the ether-extract, not being dissolved by the toluene. Chrysophanic acid remains dissolved in the petroleum spirit and toluene mixture.

FIG. 395. FIG. 396.

Cassia acutifolia. Cassia augustifolia.

Other constituents of senna are a large amount of gum, resin, the non-fermentable sugar catharto-mannit, isomeric with quercit, the bitter substance sennapicrin, oxalic, malic, and tartaric acids, combined with calcium and a little volatile oil, which seems to be a decomposition-product developing after drying.

Pharmaceutical Preparations.—COMPOUND INFUSION OF SENNA, COMPOUND LICORICE POWDER, FLUIDEXTRACT OF SENNA, SYRUP OF SENNA, U. S. P.; CONCENTRATED SOLUTION OF SENNA, B. P.

Action and Uses.—Senna is one of the best laxatives in the materia medica, and would be more generally employed were it not for its unpleasant taste and its tendency to gripe when used alone. To obviate the griping produced by it, it is usually given in combination with aromatics, as fennel and coriander, or with other purgatives, as Epsom and Rochelle Salt. Simple bitters, as gentian and colombo, increase its activity, and form with it a particularly efficient combination for constipation due to intestinal atony. Senna operates in about 4 hours, producing liquid stools. Notwithstanding the griping

it does not cause hypercatharsis, and its action is not followed by intestinal torpor or constipation. Some of its principles are absorbed and eliminated in the milk of nursing women and may purge the nursling. The chrysophanic acid when excreted in an alkaline urine will stain that fluid carmine, and be cause for alarm unless this fact be remembered. In the treatment of the constipation of pregnancy and the puerperium senna is administered usually in the form of compound licorice powder, in the dose of 1 to 2 drachms (4–8 Gm.). For the relief of habitual constipation it is frequently combined with bitter tonics, or, as used by the laity, in infusion with manna, fennel, and Epsom Salt, as the popularly known "Black Draught" (Infusum sennæ compositum). The most agreeable preparation of senna to be given to children is the confection in the dose of ½ to 1 drachm (2–4 Gm.). The dose of the fluidextract is 1 to 2 drachms (4–8 Cc.).

Allied Drugs and Products.—*Senna pods*, here figured, are said to be preferred to the leaves in the country where they are gathered, and they are more or less used in all countries. No exact study of their constituents, as compared with the leaves, has been made, though it is known that they yield more "cathartic acid" and more emodin than the latter, and are nearly free from resin and volatile oil. The constituents of the seeds, frequently so active in this family, require investigation. Some physicians have declared the action of the pods superior to that of the leaves, but the pods have not retained a high place in practice.

The genus *Cassia* contains about 400 species, and purgative properties have been found to exist very widely among them, though especially so in the sub-genus *Senna*, comprising upward of 40 species of herbs, shrubs, and trees, distinguished by the absence of glands from the common petiole, and by the broad, papyraceous legumes which do not dehisce, but merely become cleft at the margin at maturity, and contain the small triangulate seeds near the middle, attached to long funiculi.

Cassia Marilandica L. yields the *American* or *Maryland Senna* (*Folia Sennæ Americanæ; Americanische Senna*, G.; *Séné Americaine*, Fr.), official in the U. S. P. of 1870. The plant is a perennial herb belonging to the section *Chamæsenna*, and growing in low grounds throughout the eastern and central United States. It produces erect branching stems 0.9 to 1.5 M. (3–5 Ft.) high, and has pinnate leaves on petioles 25 to 50 Mm. (1–2 In.) long and with a nearly sessile gland near the base on the upper side, 6 to 9 pairs of leaflets, numerous pedunculate erect racemes near the top of the branches, showy yellow or whitish flowers with dark veins, and legumes which are finally smooth, linear, compressed, often curved, and somewhat sinuate on the raised edges; the ovate-oblong seeds are separated by transverse dissepiments. It flowers in August and ripens its fruit in October. The leaflets are 25 or 50 Mm. (1 or 2 In.) long, about 12 Mm. (½ In.) wide, on short foot-stalks, smooth, ovate-oblong to elliptic, uneven at the base, green above and paler beneath. Collected in summer, the leaflets have an herbaceous odor, but if collected in September or the beginning of October, after the plant is out of bloom, they acquire a distinct senna odor. They are thinner in texture and larger than Alexandria senna, and lose on drying about 70 per cent. of moisture. Their constituents are not definitely known, but are probably the same as those of senna, and in very much smaller amount, since the action is many times weaker.

More than half a hundred species of Cassia are recorded as being used medicinally, of which the following may be mentioned: The seeds of *C. Sieberiana* DC. are used for purging in the Soudan. The seeds of *C. Javanica* L. and some other species are employed for fish-poisoning, those of *C. occidentalis* L. as a substitute for coffee, under the name "Mogdad-coffee." Many species are used as antidotes to snake-bites and to relieve the stings of bees, some as applications to ring-worm and other parasitic diseases. The bark of *C. speciosa* Schrad, of Brazil, is sold under the name *Fedegosa*. The herbage of several is cooked as a vegetable, and some are used for poultices, while two or three present indefinite claims as antisyphilitics.

Colutea or *Bladder-senna* (*Falsche Senna*, G.; *Séné indigène, Baguenaudier*, Fr.; *Espantalobos*, Sp.) is the leaves of *Colutea arborescens* L. (Fam. *Leguminosæ*), a large shrub of southern Europe. The leaflets are in 4 or 5 pairs, oval or elliptic, obtuse or emarginate at the apex, regular at the base, thin, smooth, and dark green above, pale green beneath, and clothed with appressed hairs. They have a feeble odor and a nauseous and bitter taste. The constituents are unknown. Besides having been occasionally used as an adulterant of senna, these leaves, and the seeds also, have had some individual medicinal use as purgatives. The seeds are also regarded as emetic. The drug has been used chiefly as a domestic purgative in some parts of Europe, in an infusion prepared with 1 ounce to 1 pint (32–500 Gm.), with the addition of liquorice-root and anise-seed, and taken in divided doses in the morning, fasting. The powder and the extract have also been used, but the former is not tolerated, owing to its offensive taste, and the same objection lies against the infusion. The smoke of the dried leaves is said to act powerfully as an *errhine*. Colutea is employed in the same cases as senna.

Globularia leaves, from *G. Alypum* L. (Fam. *Globulariaceæ*), a shrub of southern Europe, have occasionally been used as a substitute for senna. They are nearly sessile, obovate-oblong, entire or slightly toothed, finely granular, and on the lower side bluish-green. Walz found in the leaves a peculiar tannin and an amorphous bitter principle, *globularin*, which is precipitated by tannin, is soluble in water, alcohol, ether, and chloroform, and is a glucoside. Heckel and Schlagdenhauffen (1882) found its composition to be $C_{15}H_{20}O_8$, and that of its decomposition-product, globularetin, C_9H_6O; the latter, heated with alkalies, yields cinnamic acid, which also exists in the leaves, together with mannit, wax, etc.

SERPENTARIA, *U. S.*—Serpentaria.

Serpentariæ rhizoma, Br.; *Serpentaria* (*Vipèrine*) *de Virginie*, Fr. Cod.; *Radix colubrina*; *R. viperina.*—*Virginia snakeroot, Serpentary, Sangree*, E.; *Virginische Schlangenwurzel*, G.; *Serpentaria de Virginia*, Sp.

The dried rhizome and roots of *Aristolochia Serpentaria* L. (*Endodeca S.*—Klotsch—*Virginia serpentaria proper*) or of *A. reticulata* Nutt. (*Texas serpentaria*) (Fam. *Aristolochiaceæ*).

Origin.—These plants are slender perennials, a foot or two high, with flexuous, rather tough stems, sparingly branched from near the base; ovate to lance-ovate thickish leaves, with more or less heart-shaped base; peculiar brownish-purple pipe-shaped flowers about an inch in length, on straggling peduncles borne mostly at the ground, without corolla, the calyx-tube sharply constricted near the middle, the limb three-lobed and obliquely expanded, the stamens 6, in pairs, connected with the style, and a 3-celled, tardily dehiscent, many-seeded pod. The Texan species is rather the larger of the two, its foliage coarser and thicker, harsh from its conspicuously reticulate sharp venation, and of a paler or more grayish green. The Virginian species extends almost throughout the eastern United States, though pretty well exterminated in many sections where it was formerly abundant. The drug is chiefly collected in the mountainous districts south of Pennsylvania and the Ohio River.

Fig. 397.

Aristolochia serpentaria, L.

Fig. 398.

Rhizome with roots.

Fig. 399.

Transverse section of rhizome.

Description.—*Virginia Serpentaria.*—Rhizome of oblique growth, 1 to 3 Cm. ($\frac{2}{5}$ to about 1 In.) long and 1 to 2 Mm. ($\frac{1}{25}$ to $\frac{1}{12}$ In.) thick, crooked and somewhat branched, bearing on the upper surface approximate, short stem-bases, and underneath a dense tress of long, thin, branched roots, straightish, except as they are bent and doubled by pressure; dull yellowish brown, internally whitish, the wood-rays of the rhizome longest in the lower side; fracture of both rhizome and roots weak; odor strong, aromatic, and camphoraceous; taste warm, aromatic, bitter.

Texas Serpentaria is larger, coarser, of a more gray color, and the roots are fewer.

Constituents.—As an aromatic bitter, serpentaria depends for its properties upon its volatile oil and bitter principle. It also contains tannin, starch, sugar, gum, and about 5 per cent. of resin, soluble in petroleum ether, with a little which is not so soluble. Of the volatile oil there is from 0.5 to 1 per cent., its important constituent being borneol. In taste it resembles valerian and camphor. The bitter constituents are several. *Aristolochin* is an amaroid ($C_9H_{10}C_6$), which has also been called *clematitin* (from *A. Clematitis* L. and other species) and *serpentarin*, and is poisonous. It is believed that a very small amount of the alkaloid *aristolochine* is present, as well as *aristinic*, *aristidinic*, and *aristolic acids*, all of the last four being found in *A. Argentina* Griseb.

Pharmaceutical Preparations.—Concentrated Solution of Serpentary, Infusion of Serpentary, Br.; Fluidextract of Serpentaria, Tincture of Serpentaria, U. S. P.

Action and Uses.—On account of its warm, pleasant taste and its stimulating effect upon gastric secretion, serpentaria is added to other drugs, as cinchona, to increase their absorption and activity. It has been used as a mild diuretic and diaphoretic in febrile states and to bring out the tardy rash of certain exanthematous diseases. In overdose it produces a sense of fulness in the head, nausea, vomiting, and abdominal griping. The dose of serpentaria in powder is 10 to 30 grains (0.60–2 Gm.). The fluidextract is given in the dose of 10 to 30 minims (0.60–2 Cc.) and the tincture in the dose of ½ to 2 drachms (2–8 Cc.).

Allied Products.—The genus *Aristolochia* comprises nearly 200 species, about a fourth of which are recorded as in medicinal use. The genus is of interest as producing what is probably the largest of known flowers. The constituents and properties of the aristolochias are in general similar to those of the drug above described. Many of them are also used as vulneraries in native practice, and several as emmenagogues. Their use in the treatment of snake-bite is, of course, fanciful. The Brazilian species, *A. cymbifera* Mart. (*A. grandiflora* Gom.), is there called *Raiz Jarinha* or *R. mil-homens*. *A. fœtida* H. B. K. is the Mexican *Hierba del Indio*. *A. pentandra* Jacq. is the Yucatan *Guaco de San Cristobal*. *A. Chilensis* Miers is the Chilian *Herba de la vierge Maria*. *A. fragrantissima* Ruiz is the Peruvian *Bejuca de la estrella*. *A. turbacensis* Kunth, of tropical America, is the *Contracapitana de Mompox* or *Capitana de Corazon*. *A. Pistolochia* L., of southern Europe, is used under the names *Pistolochia* and *Polyrhiza*, and is the "Aristolochia" of Pliny. *A. contorta* Bunge yields the Chinese drug *Fu'-ts'ing-muh-hiang*, and *A. kaempferi* Willd. yields *ona-tan-ling*. The root of *A. antihysterica* Mart., of the American tropics, is used as an emetic and diaphoretic. The East Indian species, *A. bracteata* Retz and *A. Indica* L., the latter bearing many native names, are used as anthelmintics. *A. glaucescens* H. B. K., of Guiana, yields one of the drugs called *Pareira Brava*, and is used as a purgative and diuretic. The root of *A. anguicida* Jacq., of tropical America, is poisonous, as is the rhizome of *A. grandiflora* Sm., the *Poisoned Hog-meat* of Jamaica.

SERUM ANTIDIPHTHERICUM, *U. S., P. G.*—Antidiphtheric Serum.

Diphtheria antitoxin, E.; *Serum antidiphthérique*, Fr.; *Diphtherie-Heilserum*, G.

A fluid separated from the coagulated blood of a horse, Equus caballus L, immunized through the inoculation of diphtheric toxin. It should be kept in sealed glass containers, in a dark place, at temperatures between 4.5° and 15° C. (40° and 59° F.).—U. S.

Preparation.—The immunization of the animals and the preparation of the antitoxin have been described in detail on pages 198–200 under Antitoxins. Although nearly all antidiphtheric serum used in this country is now manufactured here, there are still considerable quantities imported from France and Germany, both in the liquid and dry form.

Properties.—Antidiphtheric serum, as officially recognized, is a yellowish or yellowish-brown, transparent, or slightly turbid liquid, odorless or having a slight odor due to the presence of the antiseptic used as a preservative. Its specific gravity varies from 1.025 to 1.040 at 25° C. (77° F.). It gradually loses its power, the loss in one year varying between 10 per cent. and 30 per cent. Each container should be furnished with a label or statement giving the strength of the antidiphtheric serum, expressed in antitoxic units, the name and percentage by volume of the antiseptic used for the preservation of the liquid (if such be used), the date when the antidiphtheric serum was last tested, and the date beyond which it will not have the strength indicated

on the label or statement. The standard of strength, expressed in units of antitoxic power, should be that approved or established by the United States Public Health and Marine Hospital Service.—U. S.

The German Pharmacopœia gives the following descriptions of the liquid and dry antidiphtheric serums recognized by it: The liquid serum is a yellow, clear fluid having at most a very slight sediment; it has the odor of the preservative used. It is put up in bottles of various form and color, the contents of which contain from 100 to 3000 immunity units. The bottles most frequently used are those containing: No. O = 200 I. U.; No. I = 600 I. U. (or 500 I. U.); No. II = 1000 I. U.; ; No. III = 1500 I. U. Antidiphtheric serum which contains more than 300 immunity units in 1 Cc. is considered a high grade serum. The solid antidiphtheric serum is a dried serum of high grade, and contains at least 5000 immunity units in 1 Gm. It contains no antiseptic or other added substance. It appears as a yellowish-white powder, soluble in 10 parts of water, giving a solution which, in color and appearance, resembles the corresponding liquid serum. Single doses of from 250 to 1000 immunity units are put up in white glass-stoppered vials capable of holding from 2 to 6 Cc. The solution should be made with sterile water in the original bottle, using 1 Cc. for every 250 units, and should be prepared fresh each time.

The immunity unit may be defined as the neutralizing power possessed by an arbitrary quantity of antidiphtheric serum kept under special conditions to prevent deterioration in an authorized laboratory. From a theoretical point of view, it may be defined as that quantity of antidiphtheric serum which will just neutralize 200 minimal lethal doses of a pure poison, the latter being one containing only toxin, and no toxoid, toxone, or other substance capable of uniting with the antibodies. The unit for measuring the strength of diphtheria antitoxin is an arbitrary quantity, just as the units of all systems of weights and measures are fundamentally arbitrary quantities, so that the question of the quantity of immunity units which a particular antidiphtheric serum contains can only be determined by comparing it with the standard serum preserved by Ehrlich at the Royal Institute of Experimental Therapy, at Frankfort-on-the-Main, in Germany. (From Bulletin No. 21 of the Hygienic Laboratory, at Washington, D. C.)

While formerly it was necessary for American manufacturers of antidiphtheric serum to send their products to Germany for standardization, this work is now done by the Public Health and Marine Hospital Service, at its laboratory in Washington, where a standard serum has been prepared based on Ehrlich's immunity unit. Under an act of Congress, approved July 1, 1902, and the regulations framed thereunder, the Director of the Hygienic Laboratory is required to examine all antitoxins for purity and potency. From time to time purchases of antidiphtheric serum are made in the open market by government officials, and these are carefully examined. If found not to conform to the prescribed requirements, the manufacturer is notified and steps are taken to insure the withdrawal of that particular lot from sale. Not only is the serum tested for its potency, but great care is taken to determine its freedom from contamination by foreign bacteria, and finally to insure the absence of chemical poisons, especially tetanus toxin. The law requires all antitoxin serum to be plainly marked with the name of the article, and the name, address, and license number of the manufacturer.

Action and Uses.—These have been treated on p. 201, which see.

SEVUM PRÆPARATUM, *U. S., Br.*—Prepared Suet.

Sebum ovile, P. G.; *Suif de mouton*, Fr. Cod.; *Sevum*, U. S., 1890.—*Prepared mutton tallow*, E.; *Graisse de mouton*, Fr.; *Hammeltalg, Schöpsentalg, Unschlitt*, G.

The internal fat of the abdomen of the sheep, Ovis Aries, L., purified by melting and straining.—U. S., Br.

Preparation.—The fat, having been carefully freed from adhering membrane and blood, is cut into pieces and crushed so as to break up the cells, after which it is melted and strained through cotton or flannel. Mutton-tallow always has a peculiar, rather unpleasant odor and a finer product can be obtained by filtering the melted fat through paper in a hot-water funnel, whereby some minute odorous particles are removed which ordinarily pass through the strainer.

Properties.—Prepared suet is a white, solid fat, nearly inodorous, and having a bland taste when fresh, but becoming rancid on prolonged exposure to air. It is insoluble in water or cold alcohol; soluble in 44 parts of boiling alcohol, in about 60 parts of ether, and slowly in 2 parts of petroleum benzin. From its solution in the latter, when kept in a stoppered flask, it slowly separates in a crystalline form on standing. An alcoholic solution of prepared suet is neutral or has only a slightly acid reaction to litmus-paper moistened with alcohol. Prepared suet melts between 45° and 50° C. (113° and 122° F.) (44.4° and 48.9° C. (112° and 120° F.), Br., 47° and 50° C. (116.6° and 122° F.), P. G.), and congeals between 37° and 40° C. (98.6°–104° F.) (at about 37.8° C. (100° F.), Br.). Prepared suet should be kept in well-closed vessels, impervious to fat. It should not be used after it has become rancid.—U. S. On cooling melted suet it should be stirred while cooling to insure a smooth mass.

Composition.—According to Chevreul, mutton suet consists of 70 to 80 per cent. of stearin and palmitin, and 20 to 30 per cent. of olein, together with a trace of hircin; the latter is the glyceryl ester of hircic acid, which has a strong acid reaction and a peculiar goat-like odor, and is freely soluble in alcohol.

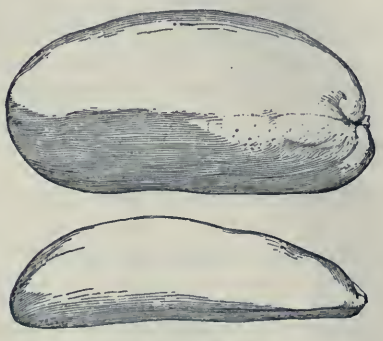
Action and Uses.—Suet when freshly prepared may be used as a soothing application to superficial burns. It enters into some official ointments.

SIMARUBACEÆ.—The Quassia Family.

The *Simarubaceæ*, almost wholly tropical, comprises 28 genera and about 125 species of shrubs and trees. The utilities of the family are restricted almost wholly to medicine, and the active constituents and properties are closely similar to those of Quassia. The fleshy fruit of *Simaba Cedron* Planch. (*Cedron Fruit*) is edible, and the seeds of species of *Irvingia* yield edible fat. That of the African species, *I. Barteri* Hook. (*A. Gaboonensis* Baill.), is used under the names *Dika* and *Gaboon chocolate*. That of *I. Oliverii* Pierre is similarly used in Cochin-China. The following drugs of the family, in addition to the Quassias, are of some importance.

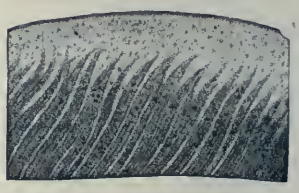
Simaruba (*Simarouba*, Fr.; *Ruhrrinde*, *G.*; *Simaruba*, Sp.) is the root-bark, its outermost layer mostly removed, of *S. amara* Aubl. (*S. officinalis* D.C.; *Quassia simarouba* L. f.), or of *S. glauca* D.C. (*S. medicinalis* Endl.; *S. officinalis* MacF.; *Quassia glauca* Spreng.). These plants are small trees of tropical America. There has been great confusion regarding their synonymy and, partly for this reason, their geographical distribution is imperfectly known. The first named occurs sparingly over a wide area in northern South America, the second in Central America and the West Indies. The bark is usually torn off in long and exceedingly tough strips, a few inches wide and 3 to 6 Mm. (⅛ to ¼ In.) thick, much inclined to be split longitudinally. The outer surface varies from pale ochre yellow to orange brown, is shortly rough-fibrous, and exhibits occasional warts. The inner surface is lighter, long and slen-

Fig. 400.



Cedron seeds (Nat.).

Fig. 401.



Simaruba bark: transverse section.

derly striate, and exhibits more or less partly detached bast-fibers. It splits rather easily, though incompletely, and has an exceedingly tough-fibrous fracture. The cross-section exhibits oblique and wavy bast-wedges, and an outer layer about half as wide, granular from numerous groups of stone-cells. That of *S. glauca* is lighter colored and usually thicker than that of *S. amara*. Simaruba bark is odorless, but exceedingly bitter. The bitter constituent or constituents of Simaruba are unknown. A little tannin and resin are contained.

Cedron Seeds (*Semen simabæ*, *Semen cedronis*, *Rattlesnake Beans*) are the seeds of the

Cedron fruit, produced by *Simaba Cedron* (R. Br.) Planch. (*Quassia C.*—R. Br.), and *S. ferruginea* St. Hil., small slender trees of South America, mostly of the northern sections. The form and size of the seeds are indicated in the accompanying illustration. They are nearly smooth, of a pale brownish-gray color, hard, inodorous, and very bitter. The bitter principle has been called *cedrin*, but its composition is not known. It occurs in yellowish or colorless crystals, soluble in water, alcohol, and chloroform, and somewhat volatile. It has been thought probable that this is identical with *valdivin* ($C_{36}H_{48}O_{20}.5HO$—Tanret), from *Simaba Valdivia* Planch., which, however, foams with water and is emetic, like saponin.

Ailanthus (*Tree-of-Heaven, Chinese Sumac*, E.; *Götterbaum*, G.; *Vernis de Japan*, Fr.) is the bark, also the leaves, of *Ailanthus glandulosus* Desf., a small tree, native of China, and well known in the United States, both in cultivation and escaped into waste places. Its foliage, and more especially the male flowers, exhale a very disagreeable odor. Flies and many other insects, as well as birds, avoid its branches. The leaves are a favorite food of the silk-worm. The *bark* is grayish brown, nearly smooth, internally yellowish, with long, straight and inconspicuous striæ, tough and fibrous, of peculiar odor and bitter taste. The *leaves* are frequently more than a meter (4 Ft.) long, and consist of about 15½ pairs of leaflets, which are short-petioluled, 2 to 3 In. long, a third as wide, ovate, acuminate and acute, at the base truncate or slightly cordate, inequilateral, obscurely few-toothed toward the base, thinnish, smooth, of disagreeable odor and bitter taste. The plant contains resin, a dark green volatile oil and an amaroid, the last most abundant in the bark, the second in the leaves. None of these constituents has been investigated.

The volatile oil, inhaled, has caused intense nausea and dizziness. The bitter principle has the tonic properties of its class and is a gastric irritant. In army hospital practice the powdered leaves, dusted over wounds, have been found very valuable in repelling flies, without affecting the patient. There are 7 species of *Ailanthus*, all Asiatic. The barks of *A. Malabarica* D.C. and *A. excelsa* Roxb. are used as vegetable bitters in India, as is the juice of the leaves and bark of the latter species. By incision the bark of the former is made to yield gum-resin, which is used in dysentery. (For a microchemical examination of the bark of *A. excelsa*, see *Phar. Jour.*, 1870–1871, pp. 154, 175, and 193.)

Samadera Indica Gaertn. (*Niota pentapetala* Lam.), a small East Indian tree, is bitter in all parts. The bark is red brown, smooth, internally whitish dotted, and has a short and finely fibrous fracture. It yields the bitter principle *samaderin*, soluble in water and alcohol, yellow with nitric or hydrochloric acid, violet red with sulphuric acid. It is used as a bitter tonic in the treatment of dysentery.

Various species of *Brucea* are used for their bitter, anthelmintic, and antidysenteric properties. The fruit of *B. sumatrana* Roxb. (*Gonus amarissimus* Lour.) yields the alkaloid *brucamarine*. The bark of *Castela Nicholsonii* Hook. is similarly used.

SINAPIS ALBA, *U. S.*—White (Yellow) Mustard.

Sinapis Albæ Semina, Br.; *Semen Erucæ*, P. G.—*Weisser Senf*, G.; *Moutarde blanche*, Fr.; *Senape Bianca*, It.; *Mostarda Branca*, Port.; *Mostaza Blanca*, Sp.

The ripe seed of *Sinapis alba* L. (*S. foliosa* Willd.; *Leucosinapis a.*—Spach.; *Brassica a.*—Boiss.—Fam. *Cruciferæ*).

White mustard is official in several other pharmacopœias besides those named above.

Origin.—This seed is derived from an annual plant, native of southern Europe and southwestern Asia, and now growing spontaneously in greater or less abundance in nearly all temperate and warm-temperate regions. It is slender, with long and widely spreading branches, the stem retrorsely rough-hairy, the leaves rough, the lower lyrate-pinnatifid, becoming gradually almost entire above. The yellow flowers are borne in terminal racemes. The mature pods are erect on spreading pedicels, are somewhat constricted between the seeds, and end in a long beak. White mustard-leaves are frequently employed in salads and are sometimes made into poultices.

Description.—White mustard-seeds are globoidal, about 2 Mm. ($\frac{1}{12}$ In.) in diameter, weigh about 0.005 Gm., and are marked on one end with a small circular hilum and on the inner side with two shallow grooves. The testa is yellowish or pale grayish brown, very finely pitted and roughish. The kernel consists of an oily embryo which possesses a curved caulicle and 2 conduplicate cotyledons. The seed is inodorous. It becomes mucilaginous in the mouth and, when masticated, has a pungent and acrid taste. The powder should be of a pale yellow or dull gray-yellow color. It should show few or no starch grains, and if 1 gram of it be exhausted by slow percolation with alcohol and the residue be mixed with 200 Cc. of water and heated to boiling, and after cooling be made up to 1000 Cc. by the addition of cold water, the addition of 4 Cc. of tenth-normal iodine solution should not produce in the solution a dark blue color. The ash should not exceed 6 per cent., and is usually less than 5 per cent.

Entire white mustard is scarcely susceptible of adulteration, but the ground or powdered article is not infrequently adulterated with starch or starchy substances. These are readily detected by the test given above. Although the ripe seed contains no starch, traces of this substance are very liable to find their way into the powder. The addition of curcuma is indicated by a bright yellow color to the powder. (For further particulars regarding adulteration, see SINAPIS NIGRA.) The powder of white mustard is readily distinguished from that of the black by its failure to give off pungent fumes when mixed with water, unless heated.

Constituents.—The inner layer of the testa contains much gum. The principal constituents of the kernel are from 20 to 25 per cent. of a bland fixed oil, the glucoside *sinalbin*, and the glucosidal enzyme *myrosin*.

Neither volatile oil nor any other pungent principle is present until after the decomposition of the sinalbin. This glucoside is peculiar in that it contains nitrogen ($C_{30}H_{44}N_2S_2O_{16}$). It is obtained by removing the fixed oil, exhausting the residue with boiling alcohol, and allowing the latter to cool, when the sinalbin separates in glassy, prismatic crystals. These are bitter, soluble in water, with difficulty in alcohol, insoluble in ether, oil of turpentine or carbon disulphide; neutral, not colored by ferric chloride, yielding white precipitates with corrosive sublimate and silver nitrate, and colored yellow by traces of alkalies. Myrosin is soluble in water, but not in alcohol, by which it can be precipitated from the concentrated infusion. If too much alcohol is employed, the myrosin is coagulated and its activity destroyed, the same result occurring from its exposure to a boiling temperature.

Sinalbin, acted upon by myrosin in the presence of water, is decomposed into white mustard oil, dextrose, and sinapine sulphate. White mustard contains more myrosin than is necessary to convert the glucoside present. This oil is *Para-hydroxy-benzyl-isothiocyanate* or "acrinyl sulphocyanide," and has the formula C_7H_7ONCS. It is a yellow, pungent liquid, powerfully irritant, but blistering more slowly than oil of black mustard. Its odor, when cold, is faint and anise-like, but, when heated, it is somewhat volatile and gives off pungent fumes similar to those of black mustard oil. It is soluble in dilute alkalies. *Acid sinapine sulphate* is $C_{16}H_{24}NO_5HSO_4$. *Sinapine* is the ester of choline, "Sinkaline," and *sinapic acid* ($C_{11}H_{12}O_5$), these separating when the yellowish mixture of the salt is boiled with alkalies.

Action and Uses.—Mustard seed may be swallowed whole in the dose of 1 or 2 teaspoonfuls 2 or 3 times a day for their laxative action, which is thought to be due to increased peristalsis brought about by mechanical irritation of the bowel wall. In powder, mustard is used as a condiment, an emetic, and as a counterirritant. Taken in small quantities with food it stimulates the secretion of gastric juice and promotes digestion, but is contraindicated in the presence of acute gastric inflammation. If used constantly in excessive quantity, however, it is apt to cause chronic gastritis. ½ to 1 tablespoonful added to a pint of tepid water will usually, if swallowed promptly, produce vomiting, and is a useful emetic in all cases of narcotic poison. Mustard is most frequently employed as a counterirritant, for which purpose it is well adapted, but should be used with care. As ordinarily used, it is made into a poultice or sinapism by the addition of water or vinegar, then spread upon a piece of linen or gauze. When applied, another piece of gauze or linen should be interposed between the skin and mustard to prevent the latter from adhering. A sinapism thus made will usually produce a good deal of burning and distinct redness of the skin in a few minutes, when it should be removed. If allowed to remain too long it will cause blisters, which may terminate in very slowly healing ulcers or even gangrene. Children and other individuals with tender skins will not tolerate a full strength mustard poultice, so that when used in these cases the action of the mustard should be mitigated by the addition of wheat flour or linseed meal in varying proportions. Mustard poultices are used to relieve the pain of flatulent colic, of acute inflammations of the abdominal and thoracic viscera, of muscular rheumatism, arthritis, neuralgia, headache, dysmenorrhœa, etc. A mustard foot-bath or pediluvium made by adding 1 or 2 tablespoonfuls of mustard to an ordinary foot-bath is popularly employed to abort forming colds. The volatile oil of mustard is a decided irritant, occasionally used as a rubefacient in place of a mustard poultice. For this purpose it is diluted with about 20 parts of alcohol or 10 parts of almond oil. It is sometimes given in the dose of ¼ to ½ minim (0.015–0.025 Cc.) to relieve the gastric atony of drunkards. In overdose it acts as a powerful, irritant poison.

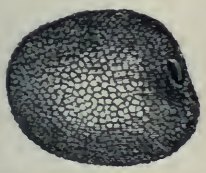
SINAPIS NIGRA, *U. S.*—Black (Red or Brown) Mustard.

Sinapis Nigræ Semina, Br.; *Semen Sinapis*, P. G.; *Semina brassicæ.—Senfsamen, Schwarzer Senf*, G.; *Moutarde noire*, Fr.; *Senape Nera*, It.; *Mostarda, Mostarda Negra*, Port.; *Mostaza, Mostaza Negra*, Sp.

The dried ripe seeds of *Brassica nigra* (L.) Koch (*Sinapis n.*—L.; *B. sinapioides* Roth.; *Melanosinapis communis* Spenn.—Fam. *Cruciferæ*). Black mustard is official in all pharmacopœias, which are divided as to classing the plant in the genus *Brassica* or in *Sinapis*. The Russian refers it to *Brassica juncea* (L.) Coss. (*Sinapis j.*—L.), the Portuguese to "*S. arvensis* L.," which is *Brassica arvensis* (L.) B. S. P., *B. Sinapistrum* Boiss. Several caution against the admixture of related seeds, especially those of rape.

Origin.—The nativity of this plant is practically the same as that of white mustard and, like that, it is widely cultivated and escaped. Both agree closely in habit, the black growing rather taller. On the black, both the pods and their pedicels are

FIG. 402.



Black mustard-seed: entire.

FIG. 403.

Embryo.

FIG. 404.

Transverse section.

erect, so that the former are appressed to the stem. The pods are more slender, more shortly beaked, and are not constricted between the seeds. The foliage is used like that of white mustard.

Description.—From 1 to 5 Mm. ($\frac{1}{25}$ to $\frac{1}{15}$ In.) in diameter, globose, deep red brown, with or without a slight grayish tinge, with a light gray or whitish hilum, the testa finely pitted, hard, mucilaginous; exalbuminous, the embryo oily, free from starch, consisting of a curved caulicle and two cotyledons, the one folded over the other; inodorous when dry, but when triturated with water of a pungent, penetrating, irritating odor; taste pungent and acrid.

Rape seed, which has been substituted or admixed, is larger, exhibits a bluish lustre, and is but slightly or not at all pungent.

The starch-test described under SINAPIS ALBA should also be employed for powdered black mustard. The ash should not exceed 6 per cent.

Although radish, turnip, and other seeds related to black mustard often occur accidentally with it in small numbers, the only admixture, in the entire condition, which need be considered is rape seed (*Brassica campestris* L.). This is larger, and readily distinguishable by its peculiar bluish-red tint. In the ground condition, black mustard is enormously subject to adulteration; more when designed for table use than for medicinal purposes. The admixture is usually flour of some kind, though powdered curcuma is very often employed. In 1891, Baert examined 27 samples purchased in pharmacies and grocery stores in Michigan, and found 19 of them adulterated. In 1 sawdust was used; in all the others the adulterant was a starchy substance, readily detected either by the microscope or by the test given with the above description.

Ground mustard is official in the British Pharmacopœia under the title Sinapis, or Mustard. Its definition calls for the ground seeds of both varieties, mixed, but does not provide for the removal of the integuments, as is done before grinding, nor for the removal of the fixed oil, as is often done by expression after powdering, the resulting cake being then re-ground. Since none of the activity resides in this fixed oil, the resulting flour is more active in proportion to the reduction in weight due to the loss of oil. If, however, a boiling temperature be reached during the process, the activity is decreased, or even destroyed, for reasons explained under S. ALBA, *Constituents.*

Constituents.—These are similar to those of white mustard, with the following exceptions: There is less gum; the fixed oil amounts to from 30 to 35 per cent.; the

glucoside is *sinigrin* instead of sinalbin; the amount of myrosin is scarcely sufficient to convert the glucoside present. Special interest in this drug, therefore, centres in sinigrin and its products. The yield of sinigrin ranges from ⅔ to 1½ per cent. It can be obtained from black mustard exhausted with boiling strong alcohol by treating it with cold water, adding a little barium carbonate to the infusion, evaporating to a syrupy consistence, and boiling this residue repeatedly with 85 per cent. alcohol, and evaporating. It occurs in white, silky, inodorous needles, or, if crystallized from water, in short glass-like prisms, soluble in water, almost insoluble in absolute alcohol, and insoluble in ether, chloroform, and benzene. The substance is lævogyric, and has a melting-point of 126° to 127° C. Sinigrin has a cooling, bitter taste. It is *Potassium myronate* ($C_{10}H_{18}NKS_2O_{10}$), and loses one molecule of water on prolonged drying *in vacuo* at 98.5°C. Its decomposition is effected by myrosin similarly to that of sinalbin (see SINAPIS ALBA), the products being sugar, potassium acid sulphate and volatile oil of mustard, oil of black mustard, or *Allyl isosulphocyanate* (see *Oleum Sinapis Volatile*), together with traces of several related substances. The yield of this oil is from ½ to ¾ of 1 per cent. of the weight of the seeds.

Action and Uses.—The properties and uses of black mustard are the same as of the white (see preceding article).

Allied Products (see also CRUCIFERÆ).—The genus *Brassica* L. is credited with about 50 species, though the precise number is uncertain. They are natives of Europe, northern Africa, and Asia, especially of the Mediterranean region. They include the cabbages, turnips, rapes, and colzas, of which there are more than a hundred distinct forms, mostly the products of cultivation. The most important, in relation to mustard, is *B. juncea* Hooker f. (*Sinapis j.*—L.), the seeds of which are known as *Russian mustard* or *Sarepta*, and are specified by the Russian Pharmacopœia as the source of black mustard. They are very similar to *B. nigra* in every way.

SODII ACETAS, *U. S.*—Sodium Acetate.

Natrium aceticum, P. G.; *Terra foliata tartari crystallisata.*—*Acetate of soda*, E.; *Acétate de soude*, Fr.; *Natriumacetat, Essigsaures Natron*, G.; *Acetato di soda*, It.

Formula, $NaC_2H_3O_2 + 3H_2O$. Molecular weight, 135.1.

It should be kept in well-stoppered bottles, and should contain in an uneffloresced condition not less than 99.5 per cent. of pure salt.—U. S.

Preparation.—Sodium acetate was first prepared by Duhamel (1736) and by J. F. Meyer (1767), and was made by Doerffurt (1793) from sugar of lead by decomposing it with sodium carbonate and sulphate. It may be obtained by neutralizing acetic acid or by decomposing lead acetate with sodium carbonate, in the latter case filtering from the insoluble lead carbonate and evaporating the clear liquids to crystallization. The salt is, however, manufactured on a large scale in the United States in the process for purifying acetic acid from wood vinegar.

Properties.—This salt crystallizes in colorless, transparent, monoclinic prisms which are odorless and have a cooling saline taste, and are somewhat efflorescent on exposure, falling in dry air to a white powder. Soluble at 25° C. (77° F.) in 1 part of water and in 23 parts of alcohol; in all proportions of boiling water and of boiling alcohol. It is about one-third as soluble in water and far less soluble in alcohol than the potassium salt. When heated to 60° C. (140° F.), the salt begins to liquefy. At 123° C. (253.4° F.) it becomes dry and anhydrous; at 315° C. (599° F.) it is decomposed with evolution of inflammable, empyreumatic vapors, leaving a black residue of sodium carbonate and carbon, which imparts to a non-luminous flame an intensely yellow color, gives an alkaline reaction with moistened litmus-paper, and effervesces with acids. The aqueous solution (1 in 20) of the salt colors litmus-paper blue, but does not redden phenolphthalein solution, unless carbonate be present. If a little of the salt be heated with 1 Cc. of sulphuric acid and 1 Cc. of alcohol, acetic ether will be formed, recognizable by its odor.—U. S. The salt is insoluble in ether. Sulphuric acid liberates from it acetic acid, and its aqueous solution becomes deep red with ferric salts, and on boiling yields a brown-red precipitate of ferric hydroxide.

Tests.—Sodium bitartrate test-solution added to a saturated aqueous solution of the salt should produce no turbidity (limit of potassium). The aqueous solution of the salt (1 in 20), slightly acidulated with acetic acid, should not be colored or made turbid

by an equal volume of hydrogen sulphide solution, when kept corked at 35° C. (95° F.) for at least half an hour, either before or after rendering slightly alkaline with ammonia-water (absence of heavy metals). 5 Cc. of the aqueous solution (1 in 10) should not respond to the modified Gutzeit's test for arsenic given under ARSENI TRIOXIDUM. If 1 Gm. of the salt be thoroughly ignited, not above red heat, and the residue extracted with boiling water until the washings cease to react with methyl-orange indicator, the mixed filtrate and washings should require for neutralization not less than 14.74 Cc. of half-normal sulphuric acid, methyl-orange being used as indicator.—U. S. Each Cc. of the sulphuric acid represents 0.06755 Gm. of crystallized sodium acetate, hence 14.74 Cc. represents 0.9956 Gm., or 99.56 per cent. The tests for limit of chloride, sulphate, and calcium have been omitted from the U. S. P., 1900, but are retained in the P. G.

Action and Uses.—Sodium acetate possesses the same medicinal properties as potassium acetate (which see). Its dose is from 10 to 30 grains (0.60–2 Gm.) as a diuretic and from 1 to 2 drachms (4–8 Gm.) as a mild laxative.

Derivative Salt.—*Sodio-theobromine Acetate. Agurin.* $C_7H_7NaN_4O_2 + NaC_2H_3O_2$.—This compound, introduced in 1901 as a diuretic, has since been used with success in doses of 1 Gm. 3 times daily, in solution or in wafers.

SODII ARSENAS, *U. S.*—Sodium Arsenate.

Natrium arsenicum.—Arseniate (arsenate) of soda, E.; *Arséniate de soude,* Fr.; *Natriumarsenat, Arsensaures Natron,* G.

Formula, $Na_2HAsO_4 + 7H_2O$. Molecular weight, 309.84.

It should contain, in an uneffloresced condition, not less than 98 per cent. of pure salt, and be kept in well-stoppered bottles.—U. S.

Preparation.—No pharmacopœia at present gives a method of preparing the salt. The Br. P., 1885, gave the following procedure: Powder finely and mix thoroughly 10 parts of arsenic trioxide, 8.5 parts of sodium nitrate, and 5.5 parts of dried sodium carbonate. Put the mixture into a large clay crucible and cover it with the lid. Expose to a full red heat till all effervescence has ceased and complete fusion has taken place. Pour out the fused salt on a clean flagstone, and as soon as it has solidified, and while it is still warm, put it into 35 parts of boiling water, stirring diligently. When the salt has dissolved filter the solution through paper and set it aside to crystallize. Drain the crystals, and, having dried them rapidly on filtering-paper, enclose them in stoppered bottles.

On fusing arsenic trioxide in the proper proportions with sodium carbonate and nitrate, carbon dioxide, CO_2, and nitrous anhydride, N_2O_3, are given off, and the residue is converted into sodium pyroarsenate, as will be seen from the equation $As_2O_3 + 2NaNO_3 + Na_2CO_3 = Na_4As_2O_7 + N_2O_3 + CO_2$. The pyroarsenate, on being dissolved in water, is converted into orthoarsenate by combining with water; $Na_4As_2O_7 + H_2O$ yields $2Na_2HAsO_4$, and this salt crystallizes with $7H_2O$. The carbonate may be conveniently replaced by an equivalent quantity of solution of caustic soda, in which the arsenic trioxide may be dissolved, and the residue left on evaporation to dryness should then be oxidized by fusion with sodium nitrate; all danger of expelling arsenic by injudicious heating will then be avoided. The same salt is also obtained on oxidizing arsenous to arsenic acid by means of hot nitric acid, dissolving the dry residue in hot water, and adding sodium carbonate as long as effervescence is produced.

Properties.—Sodium arsenate crystals are colorless, transparent, inodorous prisms having a faint alkaline taste, which usually contain $7H_2O$ or 40.4 per cent.; when obtained at a low temperature they contain $12H_2O$ or 53.7 per cent. The crystals are slightly deliquescent in a moist atmosphere, but in dry air are efflorescent and lose $5H_2O$, the white powder which is finally left having the composition $Na_2HAsO_4.2H_2O$, and containing 16.2 per cent. of water of crystallization, which is given off near 148° C. (298.4° F.). At a higher temperature the dried salt fuses, and at a red heat is converted into pyroarsenate. The official salt is soluble in 1.2 parts of water at 25° C. (77° F.), very sparingly soluble in cold, but nearly insoluble in boiling alcohol. It should respond to the tests of identity and purity given under SODII ARSENAS EXSICCATUS that follows.

Action and Uses.—The action of sodium arsenate does not differ essentially from arsenous trioxide, for which it may be substituted. It is given in the dose of $\frac{1}{20}$ to $\frac{1}{8}$

grain (0.003–0.008 Gm.). The dose of the official solution (Liquor sodii arsenatis) is from 3 to 10 minims (0.20–0.60 Cc.).

Other Sodium Arsenates.—If an excess of sodium carbonate is used in the formula given above, the aqueous solution will contain *trisodium arsenate*, and yield crystals having a stronger alkaline reaction and the composition $Na_3AsO_4.12H_2O$. With an excess of arsenic acid crystals of *monosodium arsenate*, $NaH_2AsO_4.H_2O$, may be obtained.

SODII ARSENAS EXSICCATUS, *U. S.*—Exsiccated Sodium Arsenate.

Sodii arsenas, Br.; *Natrium arsenicum exsiccatum.—Dried (anhydrous) arseniate of soda*, E.; *Arseniate de soude desséché*, Fr.; *Getrocknetes Natriumarsenat*, G.

Formula, Na_2HAsO_4. Molecular weight, 184.68.

It should contain not less than 98 per cent. of pure anhydrous salt.—U. S.

According to the temperature at which they form, crystals of sodium arsenate may contain 7, 8, or 12 molecules of water, and are more or less efflorescent, so that the per cent. of arsenic in any specimen is an uncertain quantity. Hence, considering the very poisonous property of this compound, a salt of fixed character such as the anhydrous arsenate, which is readily prepared, has very properly been made official in the Pharmacopœia, 1900, and should be employed instead of the crystallized salt with 7 molecules of water. The anhydrous salt is also official in the Br. P., but under the title SODII ARSENAS.

Preparation.—Break sodium arsenate crystals into small fragments, and allow them to effloresce at a temperature between 40° and 50° C. (104° and 122° F.) until they are completely disintegrated; then gradually increase the temperature to 150° C. (302° F.), and continue the drying until the product ceases to lose weight. Reduce it to a fine powder and transfer to dry, well-stoppered bottles.—U. S.

Properties.—The salt is an amorphous, odorless, white powder, having a mildly alkaline taste (it is very poisonous), and permanent in dry air. It dissolves in 3 (6, Br.) parts of water at 25° C. (77° F.); very sparingly soluble in cold, but nearly insoluble in boiling alcohol. It should not lose weight at 150° C. (302° F.). It imparts an intensely yellow color to a non-luminous flame.

Tests.—The aqueous solution of the salt (1 in 20) gives a precipitate (arsenate) with solutions of barium chloride (white), calcium chloride (white), and silver nitrate (dark red). The precipitate in all cases is soluble in nitric acid. If 0.5 Cc. of an aqueous solution (1 in 20) be mixed with 2 Cc. of hydrochloric acid, and a drop of this mixture be placed upon a bright piece of copper-foil, a dark steel-gray film will be deposited on applying a gentle heat (reduction to metallic arsenic). If to 2 Cc. of an aqueous solution (1 in 20), 5 Cc. of tenth-normal silver nitrate solution be added, and the precipitate redissolved by a slight excess of ammonia-water, no black precipitate of reduced silver should appear on boiling (absence of arsenite). If to 5 Cc. of an aqueous solution (1 in 20), 1 Cc. of ammonium sulphide test-solution be added, no turbidity or dark coloration should appear (absence of lead, copper, iron, etc.).—U. S. 1 Gm. of the salt dissolved in 1 Gm. of glacial acetic acid and 50 Cc. of water should require 2.03 Gm. of lead acetate for complete precipitation.—Br. This test is intended to show the absence of notable quantities of other salts. The method has been criticised by Thos. S. Barrie (*Chemist and Druggist*, 1900, p. 884) as being inaccurate and not suitable for a quantitative determination. He also states that 1 Gm. of the salt would require 3.05 Gm. of lead acetate instead of 2.03 Gm., a neutral lead arsenate being formed, and not an acid salt, as assumed by the Br. Possibly the figure 2.03 is a typographical error.

Action and Uses.—The dose of the exsiccated sodium arsenate is about two-thirds that of the hydrous salt—viz., $\frac{1}{30}$ to $\frac{1}{12}$ grain (0.002–0.005 Gm.).

Allied Compound.—*Sodii cacodylas, Natrium cacodylicum, Sodium cacodylate*, E.; *Natrium-kakodylat, Kakodylsaures Natron*, G. $(CH_3)_2AsO_2Na$.—This salt is obtained by exact neutralization of cacodylic acid, which is dimethyl arsenic acid (see under ACIDA). It contains 46.8 per cent. of arsenic, equivalent to 61.8 per cent. of As_2O_3, is very deliquescent, and contains variable quantities of water, according to the temperature at which crystallization took place and the nature of the solvent. The commercial salt mostly contains 2 to 3 molecules. It forms prismatic crystals, easily soluble in alcohol as well as water. Many commercial samples contain free cacodylic acid, the amount of which may be determined by tenth-normal alkali, using phenolphthalein as indicator.

SODII BENZOAS, *U. S., Br.*—Sodium Benzoate.

Natrium benzoicum.—Benzoate de soude, Fr.; *Natriumbenzoat, Benzoesaures Natron*, G.

Formula $NaC_7H_5O_2$. Molecular weight, 143.01.

It should be kept in well-stoppered bottles, and should contain not less than 99 per cent. of the pure salt.—U. S.

Preparation.—Add to 10 parts of benzoic acid suspended in 20 parts of hot water, gradually, 7 parts of sodium bicarbonate; after the evolution of carbon dioxide has ceased, neutralize the liquid exactly by the addition of a little benzoic acid, or if necessary with sodium bicarbonate; filter and evaporate with frequent stirring until the residue weighs between 13½ and 14 parts. As the salt separates it creeps up on the sides of the dish, and should therefore be frequently scraped off and returned to the liquid portion. When sufficiently concentrated the mass is stirred until cold, when the remaining water will evaporate. The yield is 13¼ parts. This salt being very efflorescent, the U. S. Pharmacopœia requires it to be anhydrous, for which purpose the above solution is evaporated to dryness, when the yield is 11⅘ parts.

Properties.—Sodium benzoate is described as being a white, amorphous or crystalline powder, permanent in the air, odorless, of a sweetly-astringent taste, and having a neutral reaction; soluble in 1.6 parts of water and in 43 parts (24 parts, Br.) of alcohol at 25° C. (77° F.), in 1.3 parts of boiling water, and in 12 parts of boiling alcohol. When heated the salt melts, emits vapors having the odor of benzoic acid, then chars, and finally leaves a blackened residue of an alkaline reaction which imparts to a non-luminous flame an intense yellow color. On mixing an aqueous solution of the salt with a solution of ferric chloride, a flesh-colored precipitate of ferric benzoate is produced.—U. S. According to Hager, the anhydrous salt dissolves in 13.5 parts of 90 per cent. alcohol, in 4.5 parts of 60 per cent. alcohol, in 15 parts of glycerin, and is insoluble in ether, chloroform, and volatile oils; when heated, the salt becomes brown, and afterward melts near 450° C. (842° F.) to a dark-brown mass, which, ignited, burns for a short time only.

Tests.—If 5 Cc. of diluted sulphuric acid be added to a solution of 1 Gm. of the salt in 10 Cc. of water, a white precipitate of benzoic acid will be produced, which, after thorough washing, should conform to the tests of purity mentioned under ACIDUM BENZOICUM. The aqueous solution (1 in 20) of the salt, when acidulated with hydrochloric acid and filtered, should not be colored or rendered turbid by an equal volume of freshly prepared hydrogen sulphide test-solution, after standing well-stoppered in a warm place for at least half an hour, either before or after the addition of ammonia-water to slight alkalinity (absence of metallic impurities). If 1 Gm. of dry sodium benzoate be thoroughly ignited at red heat, and the residue extracted several times with hot water, filtered and thoroughly washed, the combined filtrates should require for complete neutalization not less than 13.85 Cc. of half-normal sulphuric acid, methyl orange being used as indicator.—U. S. Each Cc. of the acid corresponds to 0.071505 Gm. of the salt, after calcination, hence 13.85 Cc. corresponds to 0.9903 Gm. or 99.03 per cent. The Br. demands that 1 Gm. shall require 6.8 to 6.9 Cc. of normal sulphuric acid, that is, 13.6 to 13.8 Cc. of half-normal acid for titration.

The U. S. P., 1900, has dropped tests for chloride, sulphate, potassium carbonate and tartrate. Except the last, these tests are still given in the Br. P.

Action and Uses.—Because of its antiseptic properties resembling those of salicylic and boric acids, sodium benzoate was at one time lauded and extensively employed as a remedy for many infectious febrile diseases, notably diphtheria, scarlet fever, puerperal septic infection, and even pulmonary tuberculosis, but the extravagant claims of its power have not been substantiated, and its use has been abandoned. It is given occasionally in acute rheumatic fever when the stomach will not tolerate the salicylates. It is used with some success in chronic gout and rheumatism, and in the so-called uric acid diathesis. The dose of sodium benzoate is rather large, from 1 to 3 drachms (4–12 Gm.) in 24 hours.

Allied Salts.—POTASSII BENZOAS, *Potassium benzoate*, $KC_7H_5O_2.3H_2O$. This salt may be prepared like sodium benzoate, 10 parts of benzoic acid requiring 8.2 parts of potassium bicarbonate, the yield being 17.5 parts of potassium benzoate of the above composition. It

crystallizes with difficulty in small plates, which effloresce in air and are very soluble in water and alcohol.

SODII BORO-BENZOAS, N. F., *Natrium boro-benzoicum, Sodium boro-benzoate,* 3 parts of powdered borax and 4 parts of sodium benzoate are dissolved in water and the solution evaporated to dryness.

SODIUM BENZOATE WITH BISULPHITE.—A mixture of 41.9 parts of sodium bisulphite and 58.1 parts of sodium benzoate, said to be a powerful antiseptic, non-poisonous, and equal to iodoform.

SODII BICARBONAS, *U. S., Br.*—Sodium Bicarbonate.

Natrium bicarbonicum, P. G.; *Natrium carbonicum acidulum.—Bicarbonate of soda, Sodium hydrocarbonate,* E.; *Bicarbonate de soude, Sel digestif de Vichy,* Fr.; *Natriumbicarbonat, Doppeltkohlensaures Natron,* G.

Formula $NaHCO_3$. Molecular weight, 83.43.

Sodium bicarbonate should be kept in well-closed bottles, in a cool place, and should contain not less than 99 per cent. of the pure salt.—U. S.

Preparation.—This salt is rarely, if ever, prepared by the pharmacist, but is manufactured on a large scale. Crystallized sodium carbonate is treated with carbon dioxide, anhydrous sodium bicarbonate, or acid carbonate, being formed and water eliminated; thus, $(Na_2CO_3 + 10H_2O) + CO_2 = 2NaHCO_3 + 9H_2O$; by using a mixture of anhydrous and crystallized sodium carbonate, a part of the eliminated water is required for converting the former into bicarbonate, the rest being allowed to escape by drainage. Sodium bicarbonate is obtained also as an intermediate product in the manufacture of the normal carbonate by the Solvay ammonia-soda process, wherein concentrated solution of sodium chloride is mixed with ammonia and then saturated with carbon dioxide under pressure. Sodium bicarbonate is precipitated and ammonium chloride remains in solution. In either case the newly formed sodium bicarbonate is washed with small quantities of water for the purpose of removing the more soluble impurities. The product of the Solvay process requires careful purification, owing to contamination with ammonium salts, especially ammonium carbonate; hence sodium carbonate, prepared from normal carbonate, is preferred for medicinal purposes.

Sodium bicarbonate is also made by passing carbon dioxide into a saturated solution of the carbonate, when the much less soluble bicarbonate is precipitated.

It is obviously not essential that the carbon dioxide needed in these operations should be generated from marble; the same gas is largely produced in establishments where saccharine substances are undergoing fermentation, and is obtained as a waste product in many chemical operations. In some manufactories the products of combustion of the fuel used for heating steam-boilers are deprived of their impurities by washing, and subsequently utilized for saturating, at least in part, the sodium carbonate with carbon dioxide. Large quantities of this salt are manufactured in the United States, and its importation has decreased from nearly 7,000,000 pounds in 1875 to about 966,000 pounds in 1897. Two large producers of sodium bicarbonate in this country are the Pennsylvania Salt Manufacturing Company, at Natrona, Pa., and the Solvay Process Company, near Syracuse, N. Y.

Commercial sodium bicarbonate is frequently contaminated with carbonate and chloride; but if a pure salt is wanted, this may be readily obtained by percolating the commercial article with cold distilled water until the washings cease to give a brown-red precipitate with mercuric chloride, and drying the purified residue with moderate heat only.

Properties.—Sodium bicarbonate is a white inodorous powder, has a mildly saline not unpleasant and scarcely alkaline taste, and is of a slight alkaline reaction to litmus, but neutral to phenolphthalein. Permanent in dry, but slowly decomposed in moist, air. It is insoluble in alcohol and ether, and requires at 15° C. (59° F.) 12 parts (U. S., P. G.), 11 parts (Br.), of water. Above 60° C. (140° F.), the solution loses carbon dioxide, and at a boiling heat the salt is entirely converted into normal carbonate. When heated, the salt is decomposed into normal carbonate, water, and carbon dioxide, and finally at 100° C. (212° F.), loses about 36.9 per cent. of its weight. At a bright-red heat it melts. To a non-luminous flame it imparts an intensely yellow color. When freshly prepared with cold, distilled water, without shaking, the solution gives a very

faint alkaline reaction with litmus-paper. The alkalinity increases by standing, agitation, or increase of temperature. Sodium bicarbonate is also soluble in glycerin without change, but in the presence of borax carbon dioxide is given off, and sodium carbonate remains behind; a mixture of sodium bicarbonate and borate is not decomposed by cold water. It dissolves with brisk effervescence in diluted acids, forming solutions in which platinum chloride causes no precipitate. If the salt is treated with a small quantity of water, insufficient for solution, the liquid may react in the cold with a solution of magnesium sulphate, producing a white precipitate, and cause with a solution of corrosive sublimate a dark brown-red precipitate, both reactions being due to sodium carbonate, which may be present in small amount. The formula of sodium bicarbonate given above represents 36.94 per cent. Na_2O, 52.35 per cent. CO_2, and 10.71 per cent. H_2O.

Tests.—If 1 Gm. of the salt be dissolved in 19 Cc. of water, it should yield a perfectly clear and colorless solution, leaving no residue. If 5 Cc. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride test-solution (absence of sulphocyanate). If 1 Gm. of the salt be dissolved, without agitation, in 20 Cc. of water at a temperature not above 15° C. (59° F.), and 0.2 Cc. of normal sulphuric acid added, no red color should appear upon the addition of 2 drops of phenolphthalein test-solution (limit of normal carbonate). The aqueous solution (1 in 20), slightly supersaturated with hydrochloric acid, should not be rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution, after standing corked in a warm place for at least half an hour, either before or after the addition of ammonia-water in slight excess (absence of heavy metals). If sodium bicarbonate be heated in a test-tube, no ammoniacal vapor should be emitted. 2 Gm. of the salt should require for complete neutralization not less than 23.74 Cc. of normal sulphuric acid, methyl orange being used as indicator.—U. S. Each Cc. of the acid represents .08343 Gm. of the bicarbonate and 23.74 Cc. represent 1.9806 Gm. or 99.03 per cent. 1 Gm. should require 11.8 to 11.9 Cc. normal sulphuric acid, corresponding to 98.45 to 99.3 per cent.—Br. 100 parts of the salt previously dried over sulphuric acid should leave a residue of not more than 63.8 Gm. when heated to redness.—P. G. A larger residue indicates the presence of carbonate or other contamination.

The tests for limit of chloride, sulphate, thiosulphate, potassium, and calcium have been omitted from the 1900 Pharmacopœia, but are retained in the Br. P. and P. G.

Action and Uses.—The alkaline action of sodium bicarbonate is milder than that of sodium or potassium carbonate. Taken for a short time in moderate doses it is the best antacid to relieve the sour eructations, heartburn, nausea, and headache of acid indigestion, but its habitual use tends to augment the acid secretions of the stomach, and thus defeat the purpose of its administration. When used as an antacid it must be given after meals, for if taken on an empty stomach it increases the acid of the gastric juice, hence taken before meals it is of service in atonic dyspepsia. In the treatment of lithæmia and to lessen the acidity of the urine sodium bicarbonate is not so efficacious as potassium bicarbonate. The alkaline treatment of acute rheumatic fever consisted in the administration of large doses of sodium bicarbonate and its local application, in solution, to the involved joints. It is to-day frequently given with the salicylates with marked success to those cases which do not yield to the salicylates alone. It seems to lessen the frequency of the cardiac complications. Its efficacy is increased if the affected joints be swathed in cloth saturated with a solution of the salt. Diabetes mellitus occurring in obese individuals is sometimes greatly benefited by the prolonged use of sodium bicarbonate. The intravenous injection of a solution of the salt has been used to relieve diabetic coma. The application of a saturated solution to burns of the first or second degree quickly relieves the pain and promotes healing. The dose of sodium bicarbonate is from 5 to 30 grains (0.30–2 Gm.), the larger doses being given in rheumatism.

SODII BISULPHIS, *U. S.*—Sodium Bisulphite.

Natrium bisulfurosum.—Bisulphite de soude, Fr.; *Natriumbisulfit, Doppeltschwefligsaures Natron*, G.

Formula, $NaHSO_3$. Molecular weight, 103.35.

It should contain not less than 90 per cent. of the pure salt and should be kept in a cool place in small, completely filled, well-stoppered bottles.—U. S.

Preparation.—This salt is employed in the arts for bleaching, and was called *leucogene* by Chaudet, who recommended it for this purpose. It is also used as *antichlor* for neutralizing the excess of chlorine after bleaching fabrics or paper-pulp, and has been recommended for the preservation of fermentable liquids and articles of food. It is prepared by saturating a solution of sodium carbonate with sulphur dioxide and crystallizing in a cool place. Warm concentrated solutions treated in this manner usually separate on cooling *sodium pyrosulphite*, $Na_2S_2O_5$.

Properties.—Sodium bisulphite is in opaque, prismatic crystals or a crystalline or granular powder, slowly oxidized and losing sulphur dioxide on exposure to air, having a faint sulphurous odor, a disagreeable sulphurous taste, and an acid reaction; soluble in 3.5 parts of water and in 70 parts of alcohol at 25° C. (77° F.), in 2 parts of boiling water, and in 49 parts of boiling alcohol. When strongly heated the salt decrepitates, and is converted into sulphur and sodium sulphate. A small fragment of the salt imparts to a non-luminous flame an intense yellow color. On adding hydrochloric acid to an aqueous solution of the salt, sulphur dioxide is evolved.—U. S. The salt being easily affected by exposure, it is difficult to keep it unaltered, even in stoppered bottles. Sodium pyrosulphite resembles the pharmacopœial salt in its properties.

Tests.—If 1 Gm. of sodium bisulphite be dissolved in 10 Cc. of diluted hydrochloric acid, with the aid of sufficient heat to expel the sulphur dioxide, the solution should not be turbid (absence of thiosulphate). The salt should not respond to the hydrogen sulphide test when applied as given under SODII SULPHIS. The salt is assayed by adding 0.25 Gm. of the finely powdered crystals to 50 Cc. of tenth-normal iodine solution in a glass-stoppered vial (of about 100 Cc. capacity), and shaking frequently during 1 hour. Tenth-normal sodium thiosulphate solution is then added with constant shaking until the brown color of the iodine disappears. Not more than 6.45 Cc. of the thiosulphate solution should be required, corresponding to not less than 90 per cent. of pure salt.—U. S.

In this titration, iodine is taken in excess, the exact amount required for the bisulphite being $50 - 6.45 = 43.55$ Cc. of tenth-normal solution. The reaction $NaHSO_3 + I_2 + H_2O = NaHSO_4 + 2HI$ shows that 1 Cc. of iodine solution containing 0.012589 Gm. of iodine is equivalent to 0.0051675 Gm. of the bisulphite. Hence 43.55 Cc. of iodine solution represents 0.225 Gm. of pure salt in 0.25 Gm. taken for assay—that is, 90 per cent. The older method of assay by adding iodine solution to the solution of the salt is defective, and has been displaced by the method above in the present Pharmacopœia. From the latter, the tests for limit of chloride and sulphate in the bisulphite have also been omitted.

Action and Uses.—The action and uses of sodium bisulphite are practically those of the other sulphites. Its dose is from 10 to 30 grains (0.60–2 Gm.).

SODII BORAS, *U. S.*—Sodium Borate.

Borax, Br., P. G.; *Natrium biboricum*, (*pyroboricum*).—*Sodium tetra- or pyroborate*, E.; *Borax*, E., Fr., G.; *Borate de soude, Bauracon, Sel de Perse*, Fr.; *Natrium-pyroborat*, G.

Formula, $Na_2B_4O_7 + 10H_2O$. Molecular weight, 379.32.

It should contain, when uneffloresced, not less than 99 per cent. of the pure salt.—U. S.

Origin and Preparation.—It is uncertain whether borax was known to and used by the ancients, and even in the Middle Ages it was frequently confounded with other salts. The observations of Homberg (1702), Geoffroy (1732), and others did not lead to correct views regarding the chemical nature of borax until Baron (1747) showed that the "sedative salt" exists in it combined with soda. The occurrence of boric acid and borax is mentioned at some length under ACIDUM BORICUM, which see. Borax is found native as *tincal* in Persia, Thibet, and other localities, as a saline incrustation on the shores of certain lakes, and as a crystalline deposit at the bottom of the borax lake in California. The incrustation and the deposit are continually renewed by crystallization from the lake waters as fast as the borax is removed. Tincal requires to be washed with a solution of caustic soda for effecting the removal of fatty matter with which the crystals are covered, and on being afterward recrystallized from water yields borax. Borax is also prepared from various native borates which are found in Nevada, in certain

parts of South America, Europe, and Asia, and which are known as the minerals *boracite, borosodocalcite, cryptomorphite,* etc. These consist of boric acid combined in varying proportions with sodium, calcium, and magnesium, and mixed with sulphates, chlorides, and silica, and yield borax on being treated with sodium carbonate, and after recrystallization from water.

Most of the borax is at present prepared from commercial crude boric acid, which is either boiled with a solution of soda, or, more generally, is fused together with calcined sodium carbonate; the impure Italian boric acid yields besides carbon dioxide also ammonia, which is also utilized. The fused mass is then dissolved in water, and this solution separated from the ferric hydroxide and other impurities suspended in the liquor, and evaporated sufficiently, when it is permitted to cool slowly, so that large crystals are obtained, from which the mother-liquor is rapidly withdrawn.

Properties.—Borax forms large, colorless, monoclinic prisms, which are transparent, inodorous, have a mild sweetish, cooling, and afterward alkaline taste, and in dry air effloresce superficially and become opaque. When heated it melts in its water of crystallization, and is converted into a light white spongy mass, which at a red heat fuses, and on cooling forms a transparent glass. Borax has the specific gravity 1.72, has a weak alkaline reaction, is insoluble in alcohol, but dissolves at 80° C. (176° F.) in 1 part of glycerin and at 25° C. (77° F.) in 20.4 parts (U. S.), 25 parts (Br.), 17 parts (P. G.) of water. The glycerin solution imparts a green color to flame (Senier and Lowe, 1878). According to Poggiale, 100 parts of water dissolve at 10° C. (50° F.) 4.65 parts, at 20° C. (68° F.) 7.88 parts, at 30° C. (84° F.) 11.90 parts, at 40° C. (104° F.) 17.90 parts, and at 100° C. (212° F.) 201.43 parts, of crystallized borax. If a saturated solution of borax is prepared at an elevated temperature and kept at a temperature exceeding 56° C. (133° F.), sodium borate containing $5H_2O$ will crystallize in octahedral crystals which are harder than borax. A cold solution of borax absorbs considerable quantities of carbon dioxide and hydrogen sulphide, both gases being again expelled on heating and evaporating the liquid. The aqueous solution (1 in 20) colors red litmus-paper blue, and yellow turmeric-paper reddish brown. After being acidulated with hydrochloric acid the solution colors blue litmus-paper red; yellow turmeric-paper remains unchanged at first, but on drying becomes brownish red, and this color is temporarily changed to a bluish black by moistening with ammonia-water. If a slight excess of sulphuric acid be added to a hot, saturated aqueous solution of the salt, shining, scaly crystals of boric acid will separate on cooling, which impart a green color to the flame of alcohol. Borax held in a non-luminous flame imparts to it an intense yellow color.

Borax is of special interest in pharmacy on account of its peculiar behavior with other substances. It is incompatible with mucilage of acacia, causing gelatinization, which can, however, be prevented by the presence of sugar; it precipitates many alkaloids from their solution, such as cocaine, morphine, atropine, quinine, etc., except in the presence of glycerin; it forms a damp, almost moist, mixture when triturated with alum; in the presence of glycerin it decomposes alkali bicarbonates with effervescence; and, lastly, while an aqueous solution of borax shows an alkaline reaction toward litmus, a solution in glycerin has a decided acid reaction, which is changed to alkaline upon large dilution with water. This last behavior is also observed with other bodies resembling glycerin, such as mannitol, glucose, etc. (see Acidum Boricum).

Composition.—The water of crystallization amounts to 47.13 per cent., Na_2O to 16.25, and B_2O_3 to 36.62 per cent. The crystallized and the anhydrous salt, $Na_2B_4O_7$, are compounds of tetra- or pyroboric acid.

Tests.—With 21 Cc. of water 1 Gm. of the salt should yield a perfectly clear and colorless solution, leaving no residue. The aqueous solution (1 in 20) should not effervesce with acids (absence of carbonate). The aqueous solution (1 in 20), slightly acidulated with hydrochloric acid, and mixed with an equal volume of hydrogen sulphide solution, should not give a turbidity or coloration after standing corked at 35° C. (95° F.) for half an hour, either before or after adding ammonia-water to slight alkalinity (absence of heavy metals). The aqueous solution (1 in 20) should not be rendered turbid by magnesia mixture (absence of phosphate). If 1 Gm. of the salt be dissolved in 20 Cc. of diluted sulphuric acid by the aid of heat, and 3 drops of indigo test-solution be added, the blue color should not be discharged after heating for 10 minutes on a water-bath (absence of nitrate).—U. S. The tests for limit of chloride

and sulphate, and absence of calcium have been dropped from the 1900 Pharmacopœia, since they are innocuous and in small quantities of no consequence medicinally. These tests are retained in the Br. P. and P. G. The time limit of heating in the test for nitrate has been added to make the test more delicate.

A solution of 1 Gm. of borax in 200 Cc. of water should require 5.2 Cc. of normal sulphuric acid for neutralization, with methyl orange as indicator.—Br. In this assay the boric acid, like carbonic acid, has no action on methyl-orange, which is affected only after this reaction is completed, $Na_2B_4O_7.10H_2O + H_2SO_4 = Na_2SO_4 + 4H_3BO_3 + 5H_2O$. Hence each Cc. of the acid represents 0.18966 Gm. of borax, and 5.2 Cc. represents 0.9862 Gm. or 98.62 per cent.

Action and Uses.—The influence of borax upon the human organism is very slight, except in large doses, which produce vomiting and purging, general depression, an enfeebled circulation, and a diffuse erythematous eruption accompanied by great swelling followed by exfoliation. Death has occurred from its use. Taken in moderate quantity it is too rapidly absorbed to exercise an influence in the alimentary canal. It is excreted almost unchanged, largely in the urine. Borax has some antiseptic power. Two per cent. solutions inhibit the growth of microörganisms, but saturated solutions fail to be destructive to any but the more delicate bacteria, hence it is only a weak germicide. On account of its antiseptic and detergent properties borax is used as a mouth-wash and gargle in aphthous stomatitis, diphtheria, thrush, and other affections of the mouth and fauces. For a like reason it is employed as an application to irritations and ulcerations occurring in the region of the anus and vulva, particularly if pruritis exists. In solution or ointment borax is sometimes efficacious in removing freckles and chloasma from the face, and may be applied with good effect in pityriasis versicolor and some other cutaneous eruptions. Leucorrhœa, especially that due to erosions of the cervix, is, as a rule, greatly benefited by copious, hot, vaginal douches of borax solutions. A saturated solution is a very efficient irrigant in subacute and chronic cystitis and urethritis. For acute or chronic conjunctivitis 1 to 2 per cent. solutions of borax are very serviceable. Given internally it has held an unmerited reputation as an emmenagogue. Gowers recommends its administration in 10- to 20-grain (0.60–2 Gm.) doses in obstinate cases of epilepsy and claims to have seen marked improvement follow its use, but the experience of other clinicians does not coincide with his, and the drug is rarely prescribed. Borax is sometimes added to food as a preservative, and this use of it has provoked much discussion as to its effect upon health. It is generally conceded that while foods thus preserved are not injurious to individuals in ordinary health, they should not be eaten by delicate persons or children. The dose of borax is from 5 to 30 grains (0.30–2 Gm.) well diluted in water.

Antipyonin.—A fine, white, argillaceous, non-caustic powder, soluble in water and said to consist of sodium polyborates. Recommended in corneal and conjunctival inflammation.

SODII BROMIDUM, *U. S., Br.*—Sodium Bromide.

Natrium bromatum, P. G.; *Bromure de sodium*, Fr.; *Bromnatrium, Natriumbromid*, G.

Formula, NaBr. Molecular weight, 102.24.

It should be kept in well-stoppered bottles, and should contain, when dried, not less than 97 per cent. of the pure salt.—U. S.

Preparation.—Sodium bromide may be prepared in a manner similar to that of potassium bromide. A solution of ferrous bromide, boiled with a solution of sodium carbonate, yields a precipitate, the filtrate from which is evaporated and crystallized.

Properties.—At a temperature of about 20° C. (68° F.) and below, colorless, transparent, oblique-rhombic prisms are obtained having the composition $NaBr.2H_2O$ (molecular weight, 138), which when heated melt and give off the water of crystallization. But when the solution is kept at a temperature above 30° C. (86° F.), anhydrous cubes of sodium bromide are obtained, which have a saline, somewhat alkaline, and slightly bitterish taste, and a neutral or faint alkaline reaction. The salt is usually met with in the form of a white crystalline, inodorous powder which is permanent in dry air, but attracts moisture from damp air without deliquescing, and is stated to be soluble in 0.8 part of boiling water, in 11 parts of boiling alcohol (U. S.), and at 25° C. (77° F.) in 1.7 (U. S.) parts of water, and in 12.5 (U. S.) or 5 (P. G.) parts of alcohol. According to

Hager, the anhydrous salt is soluble in 10 (16 Br.) parts of 90 per cent. alcohol and in 3 parts of 60 per cent. alcohol, while the hydrated salt requires 7 parts of the former and 2.25 parts of the latter for solution. The hydrated salt melts in its water of crystallization, but the anhydrous salt requires a red heat for fusion, and then volatilizes slowly without decomposition. The salt imparts to a non-luminous flame an intense yellow color, which, when observed through a blue glass, should not appear permanently red (P. G.).

Tests.—The aqueous solution (1 in 20) of the salt, slightly acidulated with hydrochloric acid and mixed with an equal volume of hydrogen sulphide solution, should not become colored or turbid after standing corked at 35° C. (95° F.) for a half hour, either before or after addition of ammonia to slight alkalinity (absence of heavy metals). Tests for calcium, sulphate, and limit of potassium have been dropped from the U. S. P., 1900. If diluted sulphuric acid be dropped upon some of the powdered salt, no yellow color should appear at once (absence of bromate). If 1 Gm. of the salt be dissolved in 10 Cc. of water and 0.1 Cc. (2 drops) of tenth-normal sulphuric acid be added, no color should be produced by the subsequent addition of a drop of phenolphthalein test-solution, even after heating (limit of alkali). 10 Cc. of the aqueous solution (1 in 20) of the salt, when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate test-solution (absence of barium). If 1 Cc. of chloroform be poured into 10 Cc. of the aqueous solution (1 in 20), then chlorine-water, which has been diluted with an equal volume of water, added drop by drop, and the mixture agitated, the liberated bromine will dissolve in the chloroform, imparting to it a yellow or brownish-yellow color, without a violet tint (absence of iodine). 1 Gm. of the salt, when completely precipitated by silver nitrate, yields, if perfectly pure, 1.824 Gm. of dry silver bromide; in the presence of sodium chloride the precipitate will weigh more. A 5 per cent. solution should not be colored red with test-solution of ferric chloride (absence of thiocyanates), Br., nor blue with 0.5 Cc. of potassium ferrocyanide solution (absence of iron), P. G. If 0.3 Gm. of the well-dried salt be dissolved in about 50 Cc. of water, and 2 or 3 drops of potassium chromate test-solution be added, it should require not less than 28.5 nor more than 30 Cc. of tenth-normal silver nitrate solution to produce a permanent red color.—U. S. Each Cc. of the silver solution represents 0.010224 Gm. of pure NaBr, hence 0.3 Gm. of pure NaBr would require 29.34 Cc. of silver solution for titration. The lower limit, 28.5 Cc., allowed in the titration, represents 0.2914 Gm. of pure bromide, or 97.13 per cent. The presence of chloride, which is the only impurity likely to be present having an action on silver solution, would tend to throw the titration figure higher than the theoretical quantity of silver solution required for the pure salt. Each 0.223 Cc. of silver solution used in excess of the theoretical quantity represents 1 per cent. of chloride present, hence 0.66 (30–29.34) Cc. excess represents 2.96 per cent. of chloride as impurity. The comments made under POTASSII IODIDUM as to the errors involved in this method of assay, apply likewise in the case of sodium bromide.

The P. G., by allowing the use of only 29.3 Cc. of tenth-normal silver solution to titrate 0.3 Gm., requires sodium bromide to be 99.5 per cent. pure. The Br. allows practically no impurities; "only the slightest reactions with the tests for chlorides, iodides, or sulphates" are allowed. The only foreign material that may be present, consequently, is water, of which a limit of 2.06 per cent. is allowed, as is shown by the titration with tenth-normal silver nitrate, of which not less than 95.8 Cc. nor more than 97.8 should be required for 1 Gm. of the salt, corresponding to 97.94 and 100 per cent. respectively.

Action and Uses.—The action and uses of sodium bromide are similar to that of potassium bromide. The sodium radicle is, however, less depressing to the human organism than is the potassium radicle. The dose is from 10 grains to 2 drachms (0.60–8 Gm.).

SODII CARBONAS, *Br.*—Sodium Carbonate.

Natrium carbonicum, P. G.; *Sal sodæ depuratus.—Pure carbonate of sodium*, E.; *Carbonate de soude*, Fr.; *Natriumcarbonat, Kohlensaures Natron*, G.

Formula, $Na_2CO_3 + 10H_2O$. Molecular weight, 284.11.

It should be kept in well-closed vessels. This form of sodium carbonate is no longer official, having been displaced by the monohydrated salt in the U. S., 1900.

Origin and Preparation.—Both sodium and potassium carbonate were known at a very remote period, and by the ancients were called *nitron* and *nitrum*, which names were afterward applied to other salts. A distinction between the alkali carbonates was not made until after Duhamel's observation (1736) had shown table-salt to be the compound of an alkali, and until Marggraf (1759) had proved this alkali to differ from the alkali procured from the ashes of plants.

Sodium carbonate exists in a large number of mineral waters, mostly, however, as bicarbonate. It is contained in the waters of certain lakes in India, Egypt, Central Africa, Mexico, and South America, and is found in the ashes of many plants growing near the seashore, such as Salsola, Statice, Salicornia, Atriplex, Mesembryanthemum, and others. These ashes are known in commerce as *barilla*, *salicor*, etc., the former containing nearly 30 per cent., the latter about 14 per cent. of sodium carbonate. *Kelp* and *varec*, the ashes of various marine algæ, contain much less soda, and are at present not employed for obtaining this salt. Egyptian *trona*, a native sodium carbonate, contains both carbonate and sesquicarbonate. In Hungary and some other countries sodium carbonate effloresces from the earth.

Natural soda is the residue obtained by the evaporation of natural alkaline waters. It is composed of sodium carbonate and bicarbonate in varying proportions, mixed with other salts, mainly sodium sulphate and chloride. In no country does it occur in such enormous quantities as in the region lying east of the Sierra Nevadas. The principal waters containing natural soda are Albart Lake, in southeastern Oregon, Mona Lake and Owen's Lake, in Mono and Inyo counties, California. By spontaneous evaporation the carbonate and bicarbonate of sodium unite to form a compound less soluble than the former but more soluble than the latter, which is called urao, or more commonly "summer soda," and has the composition $Na_2CO_3 + 2NaHCO_3 + 3H_2O$. This salt is known chemically as *sodium sesquicarbonate*. The carbonate obtainable from the above three lakes would suffice to supply the entire world demand for generations, but at present, owing to the cost of transportation, only a relatively small quantity of carbonate is produced. In reference to the production of carbonate from these lakes, a statement of Prof. G. Lunge, an eminent authority, is noteworthy. He says "there can be no doubt that the immense quantities of 'natural soda' will not be allowed to lie dormant any longer. If these lakes are once worked with the energy which is otherwise not wanting in America, the days are numbered when Liverpool soda will rule in the New York market" (*Mineral Industry*, 1892, p. 64).

The most important sources of material for the artificial preparation of sodium carbonate are cryolite and sodium sulphate and chloride. Cryolite is a mineral found almost exclusively at present in southwest Greenland, and consists of sodium and aluminum fluorides, $AlF_3.3NaF$. It is imported in immense quantities by the Pennsylvania Salt Manufacturing Company, and is also used in Denmark and Germany for the preparation of sodium carbonate and alum. Another use for cryolite is in preparing aluminum (vide). When a mixture of cryolite and chalk is cautiously heated to redness, but not to fusion, calcium fluoride and sodium aluminate are produced, this last compound being soluble in water and decomposed by carbon dioxide, which precipitates aluminum hydroxide, retaining a little sodium carbonate, while pure sodium carbonate remains in solution. The changes taking place are expressed thus: $Na_3AlF_3 + 3CaCO_3 = Na_3AlO_3 + 3CaF_2 + 3CO_2$ and $2Na_3AlO_3 + 3CO_2 + 3H_2O = 3Na_2CO_3 + 2Al(OH)_3$.

The oldest method for making sodium carbonate on the large scale is the *Le Blanc* process, devised in 1794, which was the outgrowth of necessity due to an embargo placed upon France by the rest of Europe during the French Revolution, by which the supply of potash was cut off. The French government offered a prize for a practical method for the manufacture of the carbonate from sodium chloride, which resulted in the Le Blanc process. The stronghold of this method at present is in England, but its very existence is now threatened by the Solvay process and the electrolytic process. In the Le Blanc method, common salt is first converted into sodium sulphate by sulphuric acid, whereby great quantities of hydrochloric acid are obtained as a by-product. The sulphate or *salt cake* is then mixed with ground limestone and coal in proper proportions and heated in a furnace, whereby the sulphate is reduced to sulphide by the coal, and the sulphide, acting on the limestone, forms sodium carbonate and calcium sulphide. The changes are: $Na_2SO_4 + 4C = Na_2S + 4CO$, and $Na_2S + CaCO_3 = Na_2CO_3 + CaS$.

The black mass from the furnace is known as *black-ash*, *soda ball*, or *British barilla*. The transformations are never perfect, and black-ash contains from 36 to 45 per cent. of alkali, the rest consisting of sodium chloride and sulphate, calcium sulphite, coal, calcium sulphide, and oxide. The black-ash is next leached with water, which takes up the alkali and other soluble matter and leaves an insoluble residue, called *soda waste* or *alkali waste*, which now serves to a large extent for the preparation of sodium hyposulphite. The solution is evaporated to dryness and the residue calcined, often with saw-dust, to convert any caustic alkali to carbonate; there is thus obtained a grayish mass, known as soda-ash, containing about 50 per cent. of carbonate. This is next further purified by bringing it into solution and allowing the carbonate to crystallize, thus forming the crude soda of commerce. By repeated crystallization or by conversion of the carbonate into the less soluble bicarbonate, by means of carbon dioxide passed into a solution of the carbonate, a pure product is finally obtained.

The importations of soda-ash and sal soda have fallen off greatly, owing to the increased manufacture in this country. There were imported of soda-ash, in 1893, 388,910,183 pounds, valued at $4,855,098, and in 1900, 78,571,870 pounds, valued at $648,450; of sal soda, in 1893, 27,531,554 pounds, valued at $238,029, and in 1900, 6,624,314 pounds, valued at $31,072.

The Solvay or ammonia-soda process, by which common salt is converted directly into sodium bicarbonate, is a dangerous competitor of the Le Blanc process. About 75 per cent. of the German, 60 per cent. of the French, 47 per cent. of the Austrian, and 50 per cent. of the English sodium carbonate is produced by the Solvay process. The production of soda directly from sodium chloride led to numerous investigations, and as early as 1838 it was accomplished by H. Dyar and J. Hemming; but the process, and more particularly the apparatus for the successful working of it, attained greater perfection since E. Solvay began to use it in 1865 on an extensive scale. It consists in conducting, under pressure, into a cold concentrated solution of sodium chloride, first ammonia gas and afterward carbon dioxide, when sodium bicarbonate and ammonium chloride are formed; most of the former salt is deposited, and after being heated to redness requires to be dissolved in water and crystallized in order to obtain sodium carbonate. In the first part of this process the reaction takes place between ammonium bicarbonate and sodium chloride, but the conversion of the latter salt into bicarbonate is never complete, as there is a point of equilibrium beyond which a reverse action takes place, by which sodium bicarbonate and ammonium chloride react to form sodium chloride and ammonium bicarbonate. This kind of reciprocal action is discussed in chemistry under the so-called Law of Mass Action. The changes are expressed thus: $NH_3 + H_2O + CO_2 = NH_4HCO_3$ and $NaCl + NH_4HCO_3 = NaHCO_3 + NH_4Cl$. The bicarbonate is collected, dried, and heated, whereby one-half of the carbon dioxide is recovered for subsequent use. From the mother liquors containing ammonium chloride, ammonia is recovered by heating with lime. Thus the process is made very economical, and, in addition, less labor, fuel, etc., is needed and a purer product is obtained than in the Le Blanc method.

Properties.—Sodium carbonate is in colorless, oblique-rhombic crystals, or in granular crystalline condition, inodorous, and with a harsh alkaline taste and a decided alkaline reaction. On exposure it loses water of crystallization, and ultimately falls into a soft white powder; the amount of this loss depends upon the temperature, and is in ordinary dry air of 12.5° C. (54.5° F.) 31 per cent., and at about 35° C. (95° F.) 56.6 per cent.; the last molecule of water is expelled below the boiling-point of water. The salt is soluble in 1.6 parts of water at 15° C. (59° F.), in 0.09 part at 38° C. (100.4° F.), and in 0.2 part of boiling water; insoluble in alcohol and in ether; soluble in 1.02 parts of glycerin. When heated to 34° C. (93.2° F.), the crystals fuse in their water of crystallization. At a higher temperature, the salt continues to lose water, until at last an anhydrous residue is left, corresponding to 37.07 per cent. of the weight of the crystals. At a bright-red heat the anhydrous salt fuses. To a non-luminous flame it imparts an intensely yellow color. It effervesces strongly on the addition of an acid.

Sodii carbonas venalis, *Natrium carbonicum crudum*, P. G.; *Sal sodæ*, *Soda cruda*.—*Sal soda*, *Washing soda*, E.; *Sel de soude*, Fr.; *Soda*, G.—This is the salt generally met with in commerce. It is used for preparing the pure salt by recrystallizing from hot water until the crystals respond to appropriate tests of purity, and it is advisable to agitate the cooling solution, so as to obtain small crystals or a crystalline powder, which is readily

freed from the mother liquor by draining and washing with a little cold water. The pure salt should be kept in a well-stoppered bottle in a cool place. 20 grains of it neutralize 9.7 grains of citric acid or 10½ grains of tartaric acid.

Tests.—Commercial sodium carbonate contains small but variable quantities of sulphate and chloride, and its solution in water acidulated with nitric acid therefore produces precipitates with barium chloride and with silver nitrate. Cryolite is the source of an impurity which is sometimes met with, and which consists of alumina rendered soluble in water by the soda; it is best detected by acidulating its solution in water with hydrochloric acid, heating to boiling, and then supersaturating with ammonia, when gelatinous aluminum hydroxide will be precipitated. The pure salt with 10 molecules of water of crystallization is official in the Br. P. and P. G., but not in the U. S., 1900. The Br. P. has tests for sulphocyanate, calcium, and potassium, and for limit of chloride, sulphate, thiosulphate, sulphite, while the P. G. has tests only for sulphate, chloride, and ammonia, in addition to the test for heavy metals which is common to all pharmacopœias. These tests are practically the same as those given in the U. S., 1890, which are as follows: A 5 per cent. aqueous solution of the salt should be perfectly clear and colorless, leaving no insoluble residue. If 5 Cc. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride test-solution (absence of sulphocyanate). If to the aqueous solution (1 in 20), slightly supersaturated with hydrochloric acid, an equal volume of hydrogen sulphide test-solution be added, no turbidity or coloration should be produced after standing corked in a warm place for half an hour, either before or after the addition of ammonia-water in slight excess (absence of arsenic, lead, iron, aluminum, etc.). If 5 Cc. of the aqueous solution be slightly supersaturated with acetic acid, the addition of 0.5 Cc. of ammonium oxalate test-solution should produce no turbidity (absence of calcium). If 5 Cc. of the aqueous solution be slightly supersaturated with acetic acid, the addition of 0.5 Cc. of sodium cobaltic nitrite test-solution should not render it turbid within one hour (limit of potassium). If 1.2 Gm. of the salt be dissolved in 10 Cc. of diluted nitric acid, then 0.5 Cc. of tenth-normal silver nitrate solution added, and the precipitate, if any, be removed by filtration, the clear filtrate should remain unaffected by the addition of more silver nitrate test-solution (limit of chloride). If 2.5 Gm. of the salt be dissolved in 10 Cc. of diluted hydrochloric acid, then 0.1 Cc. of nitric acid and 0.1 Cc. of barium chloride test-solution added, and the precipitate, if any, be removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of sulphate, sulphite, and thiosulphate). If the crystallized salt be heated in a test-tube, the vapor of ammonia should not be evolved. 1 Gm. of salt should require not less than 6.9 Cc. (Br.), 7 Cc. (P. G.), of normal sulphuric acid for titration. Each Cc. of the acid represents 0.14205 Gm. of the crystallized salt. Hence the Br. requires 98 per cent. and the P. G. 99.44 (99.5) per cent.

Composition.—Pure crystallized sodium carbonate contains 62.93 per cent. of water, 21.7 per cent. of Na_2O, and 15.37 per cent. of CO_2. When boiled with a little water a salt is deposited containing only 14.5 per cent. of water $= 1H_2O$. Several other salts are obtainable, which crystallize with 3, 5, and $7H_2O$.

Action and Uses.—Sodium carbonate may be given internally in doses of 10 to 30 grains (0.60–2 Gm.) for the same conditions for which the bicarbonate is administered, but because its action is much more irritating than the latter salt it is rarely used. Solutions varying in strength from 10 to 20 grains to the ounce (0.60–1.30 Gm., 30 Cc.) are applied with great benefit to dry, chronic skin eruptions, as psoriasis, lichen, pityriasis, prurigo, etc., while pustular and vesicular affections are unsuited for its use. A frequent method of its employment for diseases of the skin is to add from 4 to 6 ounces (16–24 Gm.) of the salt to a general bath, which should last about ½ hour.

SODII CARBONAS EXSICCATUS, *Br.*—Dried Sodium Carbonate.

Natrium carbonicum siccum, P. G.—*Dried carbonate of soda, Exsiccated sodium carbonate*, E.; *Carbonate de soude sec*, Fr.; *Entwässerte Soda, Getrocknetes Natriumcarbonat*, G.

Formula, Na_2CO_3, Br.; $Na_2CO_3 + 2H_2O$, P. G. Molecular weight, 105.31, Br.; 141.07, P. G.

This salt has been dropped from the U. S., 1900. The monohydrated salt, $Na_2CO_3.H_2O$, which is the only form official now, stands very close to it in percentage composition.

Preparation.—Sodium carbonate, 200 Gm.; to make 100 Gm. Break the salt into small fragments, allow it to effloresce by exposure to warm air at a temperature not exceeding 25° C. (77° F.) for several days, then expose it to a temperature of about 45° C. (113° F.) until it has been converted into a white powder weighing 100 Gm. Pass the powder through a sieve and preserve it in well-stoppered bottles.—P. G.

This salt is intended to facilitate the dispensing of sodium carbonate. The warm air to which the crystallized salt is to be exposed in the beginning should be of a lower temperature than the melting-point (34° C.) of the salt, when a light and voluminous powder will be obtained. Working strictly according to the directions, the salt will have the composition given above, and probably is a mixture of the mono- and terhydrated carbonate. Near and above 40° C. (104° F.) a salt of the formula $Na_2CO_3.H_2O$ is readily obtained, weighing $1\frac{3}{8}$ ounces, from 4 ounces of the crystallized salt. The product of the British Pharmacopœia is denser, the salt being at first fused in its water of crystallization, and afterward rendered anhydrous.

Properties.—Dried sodium carbonate is a soft white powder which answers to the tests and reactions of the crystallized salt. It is permanent at a temperature of 30° or 35° C. (86° or 95° F.), but at low temperatures absorbs moisture. 1 Gm. should require not less than 14 Cc. of normal hydrochloric acid for titration, showing at least 73.7 per cent. of anhydrous carbonate, Na_2CO_3.—P. G.

Action and Uses.—Dried sodium carbonate was used as a more stable form of sodium carbonate, but is displaced in the 1900 revision of the Pharmacopœia by the monohydrated salt.

SODII CARBONAS MONOHYDRATUS, *U. S.*—Monohydrated Sodium Carbonate.

Formula, $Na_2CO_3 + H_2O$. Molecular weight, 123.19.

It should contain not less than 85 per cent. of the anhydrous salt, Na_2CO_3, corresponding to not less than 99.5 per cent. of the crystallized monohydrated salt.—U. S.

It is prepared by crystallizing ordinary sodium carbonate above 35° C. (95° F.) and possesses the advantage of being comparatively stable in the air. In a test made on a sample exposed in an open beaker, 0.14 per cent. of moisture was taken up during the first week and only 0.02 per cent. more during the second. In view of its purity and convenience in handling, the salt is to be preferred to the efflorescent salt containing 10 molecules of water of crystallization, and is the only form recognized in the U. S., 1900.

Properties.—It is a white, crystalline, granular powder, quite stable under ordinary conditions, but in dry air, at or above 50° C. (122° F.), the salt effloresces, and at 100° C. (212° F.) it loses all of its water (14.52 per cent.). It is soluble in 2.9 parts of water at 25° C. (77° F.), in 1.8 parts of boiling water, and 1.02 parts of glycerin. In other respects it is like ordinary sodium carbonate. The Pharmacopœia has omitted all tests for impurities except that for heavy metals, which is described under Sodii Carbonas (which see). To neutralize 1 Gm. of the salt, or 0.855 Gm. of the anhydrous salt, dissolved in 10 Cc. of distilled water, should require not less than 32.3 Cc. of half-normal sulphuric acid solution, 3 drops of methyl-orange test-solution being used as indicator.—U. S. Each Cc. of the acid represents 0.0308 Gm. of the monohydrated, or 0.02633 Gm. of the anhydrous salt; hence 32.3 Cc. of the acid represents 0.9948 Gm. of the former, or 0.8504 Gm. of the latter salt, each corresponding to 99.48 per cent.

Action and Uses.—The uses of monohydrated sodium carbonate differ in no respect from those described under sodium carbonate. The dose of the monohydrated salt is about ½ that of the ordinary carbonate containing 10 molecules of water, or from 2 to 10 grains (0.12–0.60 Gm.).

SODII CHLORAS, *U. S.*—Sodium Chlorate.

Natrium chloricum.—Chlorate de soude, Fr.; *Natriumchlorat, Chlorsaures Natron*, G.

Formula, $NaClO_3$. Molecular weight, 105.7.

Sodium chlorate should be kept in glass-stoppered-bottles, and *great caution* should

be observed in handling the salt, as dangerous explosions are liable to occur when it is mixed with organic matters (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances, and either heated directly or subjected to trituration or concussion. It should contain not less than 99 per cent. of pure salt.—U. S.

Preparation.—This salt is most conveniently obtained, according to Wittstein, by preparing sodium bitartrate from 9 parts of crystallized sodium carbonate and 9.5 parts of tartaric acid, and adding the hot solution to one containing 8 parts of potassium chlorate. The cold liquid is filtered from the precipitated potassium bitartrate, evaporated and crystallized. The last traces of bitartrate may be removed by recrystallization from alcohol. The yield is about 7.5 parts. The salt is also formed, like the corresponding potassium salt, by passing chlorine into solution of soda and boiling; the resulting chlorate requires to be freed from chloride by repeated crystallization, involving considerable loss, owing to the ready solubility of both salts.

Hager recommends the following: Dissolve 100 parts of potassium chlorate and 60 parts of official dry sodium carbonate in 600 parts of warm water; allow to cool, add 300 parts of alcohol, set aside in a cool place for two days, decant the solution, distil off the alcohol, evaporate to crystallization, and purify by recrystallization. The yield is about 85 parts.

Properties.—Sodium chlorate crystallizes in the form of regular cubes, combined with the dodecahedron and tetrahedron. The crystals are colorless and transparent, or the salt is seen in a white crystalline powder, and is permanent in the air, inodorous, and has a cooling saline taste; it is soluble at 25° C. (77° F.) in 1 part of water, and in about 100 parts of alcohol; in 0.5 part of boiling water, and in about 40 parts of boiling alcohol; also soluble in 5 parts of glycerin. When heated, the salt melts, then gives off oxygen (about 45 per cent. of its weight), and finally leaves a residue of sodium chloride readily soluble in water, and yielding, with silver nitrate test-solution, a white, curdy precipitate, insoluble in nitric acid. To a non-luminous flame it imparts an intensely yellow color. The aqueous solution is neutral to litmus-paper. When a crystal of the salt is dropped into hydrochloric acid, the liquid assumes a deep greenish-yellow color and emits the odor of chlorine.

Tests.—A saturated aqueous solution should not be rendered turbid by sodium bitartrate test-solution (limit of potassium). The aqueous solution (1 in 20) of the salt, upon the addition of 1 Cc. of ammonium sulphide test-solution, should not develop a dark coloration (absence of lead, copper, etc.). Tests for chloride, sulphate, calcium, and magnesium have been dropped from the U. S. P., 1900. The salt is produced in such high degree of purity that the tests are scarcely called for.

Action and Uses.—The action and uses of sodium chlorate correspond closely to those of potassium chlorate. Its greater solubility is an advantage when stronger solutions are desired. Its dose is from 5 to 20 grains (0.30–1.30 Gm.).

SODII CHLORIDUM, *U. S., Br.*—Sodium Chloride.

Natrium chloratum, P. G.; *Sal commune, s. culinare.—Common salt, Table-salt, Sodium chloride*, E.; *Chlorure de sodium, Sel commun, Sel de cuisine*, Fr.; *Chlornatrium, Kochsalz*, G.

Formula, NaCl. Molecular weight, 58.06.

It should contain when dried not less than 99 per cent. of the pure salt.—U. S.

Origin and Preparation.—Sodium chloride is found native in extensive beds and in different geological formations, though mostly associated with clay and calcium sulphate, and constitutes rock-salt or sal gemmæ if very pure and transparent. This is mined, mechanically freed from the adhering impurities, and sold as rock-salt or purified by recrystallization. In some places holes are dug into the rock and filled with water, which is pumped up when nearly saturated with salt and evaporated.

Most saline springs contain sodium chloride. If the salt is present in sufficiently large proportion, it is recovered by evaporation; but if present in the solution only in limited proportion, the spring water is first concentrated, in some parts of France and Germany, by pumping it up on a high scaffolding and causing it to trickle over layers of brushwood, whereby, from the largely-extended surface exposed to the air, much water is evaporated, and a brine is obtained which may be economically concentrated by artificial heat. Some-

times the brine contains also considerable proportions of gypsum and sodium sulphate, which salts are deposited from the boiling brine and raked out; when nearly free from these salts and sufficiently concentrated, the liquor is no longer mixed with fresh portions of the brine, but is maintained at an elevated temperature and the salt removed as it crystallizes. The size of the crystals, called grain of the salt, varies with the heat, and increases as the temperature falls.

Sea-water is a solution of various salts, prominent among which is sodium chloride, which is contained in the waters of the large oceans to the amount of from 2.6 to 2.9 per cent., but is much less in the large bays and seas which are surrounded by land, and sinks—for instance, in the water of the Baltic Sea—to ½ per cent. The extraction of the salt from sea-water depends upon the climate, the water being removed either by freezing or by evaporation. When frozen, sea-water yields pure ice and leaves a more concentrated saline solution. In warmer countries the concentration is effected by spontaneous evaporation in shallow pits, the brine as it concentrates being conducted into other pits, and finally into reservoirs, where the salt is deposited.

The mother-liquors which are obtained in the several processes described are solutions of various salts, usually sulphates and chlorides, in some cases also of sodium, potassium, calcium, and magnesium bromides, and they frequently yield salts or double salts of definite composition by being concentrated and exposed to either a low or an elevated temperature; they are used up in the preparation of sodium sulphate, magnesium sulphate, and bromine.

In addition to the large quantities of salt obtained in the United States, about 750,000,000 pounds of it are annually imported.

Properties.—When crystallized by spontaneous evaporation sodium chloride forms transparent cubes; but when the solution is evaporated at an elevated temperature, the crystals aggregate on the surface of the liquid in the form of white or translucent hollow pyramids. It is very frequently kept in the form of a white, granular, crystalline powder, which is inodorous and permanent in the air, unless contaminated with magnesium chloride, when it becomes moist in a damp atmosphere. On the application of heat sodium chloride usually decrepitates, and at a red heat it melts and is slowly volatilized. It has a neutral reaction to test-paper, a density of 2.16, and a purely saline taste. It is very sparingly soluble in strong alcohol, and requires a little less than 3 parts of hot or cold water for solution. 100 parts of water dissolve at 0° C. (32° F.) 35.52 parts, at 14° C. (57.2° F.) 35.87 parts, at 25° C. (77° F.) 36.13 parts, at 60° C. (140° F.) 37.25 parts, and at 100° C. (212° F.) 39.61 parts, of sodium chloride (Poggiale). On cooling the saturated aqueous solution to below the freezing-point of water, transparent colorless prisms, $NaCl.2H_2O$, are obtained, which melt above 0° C. (32° F.) and deposit a granular powder of the anhydrous salt. Dilute aqueous solutions of sodium chloride produce at a low temperature ice which is free from the salt, and concentrated solutions deposit crystals of the salt before they freeze. When a saturated solution of sodium chloride is mixed with a large volume of concentrated hydrochloric acid, or is saturated with hydrochloric acid gas, the pure salt is precipitated. A fragment of the salt imparts to a non-luminous flame an intense yellow color; the aqueous solution, acidulated with nitric acid, yields with test-solution of silver nitrate a white precipitate soluble in ammonia.

Composition.—Sodium chloride contains 60.59 per cent. of chlorine and 39.41 per cent. of sodium. Heated with sulphuric acid, hydrochloric acid is given off.

Tests.—The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not be colored or rendered turbid when mixed with an equal volume of hydrogen sulphide solution and allowed to stand corked at 35° C. (95° F.) for ½ hour, either before or after addition of ammonia-water in slight excess (absence of heavy metals). If 2 Gm. of the salt be digested for some hours with 25 Cc. of warm alcohol, the cold and filtered alcoholic solution evaporated to dryness, the residue dissolved in 5 Cc. of water, 1 Cc. of chloroform added, then chlorine-water previously diluted with twice its volume of water, drop by drop, with constant agitation, the chloroform should be free from any yellow to orange or violet color (absence of bromide or iodide). Tests for calcium, magnesium, potassium, and sulphate have been omitted from the U. S. P., 1900, but are retained in the Br. P. and P. G. If 1 Gm. of well-dried sodium chloride be dissolved in distilled water to 100 Cc., 10 Cc. of the solution should require not less than 17 Cc. of tenth-normal silver nitrate solution for titration, using a few drops of potassium chromate test-solution as indicator.—U. S. Each Cc. of silver

solution represents 0.005806 Gm. of NaCl, hence 17 Cc. represents 0.0987 Gm., or 98.7 per cent.

Action and Uses.—Sodium chloride is one of the most important natural constituents of the body, occurring in all of the fluid and solid tissues except the enamel of the teeth. When introduced into the stomach in moderate amounts it exerts no demonstrably active effect, but appears to aid the digestion of certain foods, probably by increasing their solubility and by stimulating the secretion of gastric juice. In overdose it causes vomiting and diarrhœa. Its long-continued use in excessive amounts may result in scurvy. Sodium chloride gives relief in that form of dyspepsia in which decomposition of food in the stomach causes acid eructations, heartburn, and flatulence. It has been proposed and employed as a remedy in intermittent fever, although its effect upon the malarial parasite has not been thoroughly studied. Its antiperiodic action is greatly inferior to that of quinine. Teaspoonful doses of dry salt repeated every fifteen minutes are said to be frequently successful in controlling hæmoptysis. The intravenous or hypodermic injection of "normal salt solution," called also "physiological saline solution," constitutes one of the most important therapeutic applications of sodium chloride. The saline strength of these solutions is supposed to be the same as of the blood serum, and varies, according to different authorities, from $\frac{6}{10}$ to $\frac{9}{10}$ per cent., or, as it is roughly calculated, 1 teaspoonful of sodium chloride to 1 pint of water. The solution must be thoroughly sterilized, and at a temperature of about 105° F., before its introduction into the vein. There is no more efficient measure at our command than this to aid a patient in profound shock, whether it be due to injury, drug narcosis, or the intoxication of acute infectious diseases. It is also of value in conjunction with the hot pack to aid in the elimination from the blood of poisons which cause uræmic and diabetic coma. The quantity infused varies from 1 to 4 pints. A tepid solution of common salt acts as a prompt and useful emetic to empty an overloadad stomach or one containing narcotic poisons. Sodium chloride is to be remembered as a chemical antidote to silver nitrate. Enemas of salt water are serviceable for the removal of hardened fecal masses and round and thread worms from the rectum. Weak salt solutions (20 to 60 grains (1.30–4 Gm.) to the pint [480 Cc.]) applied by an atomizer or nasal douche are useful in subacute and chronic inflammations of the nares, pharynx, and larynx. Salt and water may be employed as a vaginal injection in leucorrhœa, and as a wash for pruritis vulvæ and to relieve the pain of insect stings. Salt water baths are somewhat stimulating, and are useful in depraved conditions of the body, and in chronic, sluggish skin diseases.

SODII CITRAS, *U. S.*—Sodium Citrate.

Natrium citricum.—*Citrate de soude*, Fr.; *Natriumcitrat, Citronensaures Natron*, G.

Formula, $2Na_3C_6H_5O_7 + 11H_2O$. Molecular weight, 709.20.

It should contain not less than 97 per cent. of pure salt $[C_3H_4(OH).(COONa)_3 + 11H_2O]$, and should be kept in well-stoppered bottles.—U. S.

Preparation.—Citric acid, being tribasic, is capable of forming three different salts with sodium, but the normal salt, or trisodium citrate, is the one recognized in the Pharmacopœia. No official method of preparation is given, but the following process may be employed: A solution of citric acid is neutralized with sodium carbonate or bicarbonate, concentrated, and allowed to crystallize. The crystals are filtered off, drained, removed to bibulous paper or porous plates, and dried. To make 100 parts of the salt requires 58.8 parts of citric acid and 121.5 parts of crystallized sodium carbonate, 52.7 parts of monohydrated sodium carbonate, or 71.6 parts of sodium bicarbonate.

Properties.—The salt occurs as a white, odorless, granular powder, having a cooling saline taste and a slightly alkaline reaction to litmus-paper. It effloresces slowly when exposed to dry air. At 150° C. (302° F.) it loses all of its water of crystallization (27.73 per cent.), and at red heat it decomposes, leaving a black residue of sodium carbonate and carbon, which is strongly alkaline and effervesces with an acid. The salt is soluble in 1.1 parts of water at 25° C. (77° F.) and in 0.4 part of boiling water, but only slightly soluble in alcohol. It imparts an intense yellow color to a non-luminous flame, and 10 Cc. of its aqueous solution (1 in 20) with 2 Cc. of calcium chloride test-solution yields a clear mixture, which upon boiling deposits a white granular precipitate (citrate).

Tests.—The aqueous solution (1 in 20) should not produce a red color with a drop

of phenolphthalein test-solution, nor effervesce on addition of an acid (absence of carbonate). The U. S. P., 1900, has omitted tests for sulphate and chloride. The aqueous solution (1 in 20), slightly acidulated with acetic acid, should give no turbidity or coloration when mixed with an equal volume of hydrogen sulphide solution and kept corked at 35° C. (95° F.) for at least ½ hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals). If 1 Gm. of the salt be thoroughly ignited at a temperature not above red heat, and the residue extracted with boiling water until the washings cease to react with methyl-orange as indicator, the mixed liquids should require not less than 16.4 Cc. of tenth-normal sulphuric acid solution for neutralization, with methyl-orange as indicator.—U. S. Each Cc. of the acid represents 0.0591 Gm. of the salt that has been converted into carbonate, hence 16.4 Cc. of the acid represents 0.9697 Gm. of the salt, or 96.97 (97) per cent.

Action and Uses.—In small doses, 10 to 40 grains (0.60–2.60 Gm.), sodium citrate possesses diuretic and antilithic properties similar to those of potassium citrate. In doses of from 6 to 10 drachms (24–40 Gm.) it is a mild laxative, resembling magnesium citrate in its action.

SODII CITRO-TARTRAS EFFERVESCENS, *Br.*—Effervescent Sodium Citro-tartrate.

Preparation.—Take, in fine powder, sodium bicarbonate, 17 ounces; tartaric acid, 9 ounces; citric acid, 6 ounces; refined sugar, 5 ounces. Mix the powders thoroughly, place them in a dish or pan of suitable form heated to between 93.3° to 104.4° C. (200°–220° F.), and when the particles of the powder begin to aggregate stir them assiduously until they assume a granular form; then by means of suitable sieves separate the granules of uniform and most convenient size, and preserve the preparation in well-closed bottles.—Br.

If kept dry, this citro-tartrate is preferable to a mixture of the powdered ingredients, which soon undergoes decomposition. Thrown into water, it dissolves with brisk effervescence.

Action and Uses.—This preparation presents a means of obtaining the diaphoretic, diuretic, and laxative effects of sodium citrate and tartrate under peculiarly favorable conditions. The carbonic acid gas liberated on the addition of water enhances the acceptability of the salts to the stomach and tends to allay nausea and vomiting. It is given in mild febrile attacks and acute rheumatic fever. The dose is from 1 to 2 drachms (4–8 Gm.), in a wineglassful or more of water, to be drunk during effervescence.

SODII HYDROXIDUM, *U. S.*—Sodium Hydroxide.

Soda, U. S., 1890, *Soda caustica*, *Natrium causticum*, *Natrium hydricum*.—*Caustic soda*, *Sodium hydrate*, E.; *Soude caustique*, Fr.; *Natron*, *Aetznatron*, G.

Formula, NaOH. Molecular weight, 39.76.

It should be kept in well-stoppered bottles made of hard glass, and should contain not less than 90 per cent. of pure anhydrous sodium hydroxide, and not more than 2 per cent. of other inorganic substances, with the exception of water.—U. S.

Preparation.—Sodium hydroxide is prepared by the same methods as have been described under Potassium Hydroxide (which see), in which corresponding sodium compounds are used in place of those of potassium. The article commonly found on the market is known as *soda by lime*, which is formed by the action of slaked lime on sodium carbonate in solution, $Na_2CO_3 + Ca(OH)_2 = CaCO_3 + 2NaOH$. The clear supernatant liquid is evaporated to dryness, fused, and cast in molds. *Soda by baryta* and *soda by alcohol* are very pure, but the purest product is obtained by the action of pure metallic sodium on water. Large quantities of solution of sodium hydroxide are now made electrolytically (see Potassium Hydroxide) from sodium chloride, in England, the Continent of Europe, and at Niagara Falls. While many electrolytic processes have been devised, those in active operation are the Castner-Kellner, the Le Sueur, and the Dow process. Large manufacturers of sodium hydroxide in this country are the Solvay Process Company, of Syracuse, N. Y., and Detroit, Mich., the Michigan Alkali Company, of Wyandotte, Mich., and the Matthiessen Alkali Company, of Niagara Falls.

Properties.—Sodium hydroxide is white, hard, opaque, inodorous, very alkaline in reaction, strongly corrosive, and of an intensely acrid and caustic taste. It is usually seen in irregular fragments having a fibrous appearance, or in cylindrical sticks which are crystalline upon a fresh fracture. On exposure to the atmosphere it absorbs water and is liquefied, and subsequently it solidifies again and becomes efflorescent, in consequence of the absorption of carbon dioxide and the crystallization and efflorescence of sodium carbonate. A concentrated aqueous solution when exposed to a temperature of—10° C. (14° F.) or less, separates thick tabular crystals of the hydrate, $2NaOH.7H_2O$, which melt above 6° C. (42.8° F.). The strong aqueous solution of sodium hydroxide dropped into test-solution of tartaric acid, so that the latter remains in excess, deposits acicular crystals of acid sodium tartrate, which are dissolved on the addition of more sodium hydroxide or of water. It is soluble in 1 part of water at 25° C. (77° F.) and in 0.8 part of boiling water; very soluble in alcohol. When heated to about 525° C. (977° F.) sodium hydroxide melts to a clear, oily liquid, and at a bright red heat it is slowly volatilized unchanged. When introduced into a non-luminous flame it imparts to it an intensely yellow color. A solution of sodium hydroxide, even when greatly diluted, gives an intensely alkaline reaction with litmus-paper.—U. S.

Tests.—Alcohol dissolves sodium hydroxide, but leaves most of the salts behind which are likely to be present. The aqueous solution (1 in 20) should be perfectly clear and colorless (absence of organic matter), and after being acidulated with acetic acid, should yield no precipitate on the addition of an excess of tartaric acid test-solution (limit of potassium). If 1 Gm. of sodium hydroxide be dissolved in 20 Cc. of water and the solution slightly supersaturated with hydrochloric acid, the solution should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution, after standing corked at 35° C. (95° F.) for at least ½ hour, either before or after making slightly alkaline with ammonia-water (absence of arsenic, copper, lead, etc.). If 0.7 Gm. of sodium hydroxide be dissolved in 1.5 Cc. of water and the solution added to 10 Cc. of alcohol, not more than a slight white precipitate should occur within 10 minutes (limit of silicate, etc.). On adding a slight excess of diluted sulphuric acid to 10 Cc. of a 10 per cent. aqueous solution of sodium hydroxide, no distinct effervescence should occur (limit of carbonate). About 1 Gm. of sodium hydroxide, weighed accurately in a stoppered weighing-bottle, is dissolved in about 50 Cc. of water, and titrated with normal sulphuric acid-solution, with methyl-orange solution as indicator; multiply the number of Cc. of acid consumed by 3.976, and divide this product by the weight of sodium hydroxide taken; the quotient represents the percentage of pure NaOH present.—U. S. Each Cc. of normal sulphuric acid neutralizes 0.03976 Gm. of NaOH. If n Cc. of acid are required for g Gm. of hydroxide titrated, the weight of pure NaOH in 100 Gm. of the hydroxide will be $\frac{0.03976 \times n}{g} \times 100 = \frac{3.976\ n}{g}$. Hence the rule as stated above. The quotient should not be less than 90.

Commercial sodium hydroxide sometimes contains sodium aluminate, which is soluble in water, but insoluble in alcohol; on treating with excess of ammonium chloride, it will separate as a white gelatinous precipitate, which is dissolved again by excess of hydrochloric acid. Sulphide, if present, will cause the precipitate with a lead salt to be more or less brown, instead of white, and cyanide will produce Prussian blue on adding to the solution a little ferrous and ferric salt and acidulating with hydrochloric acid. The tests for limit of chloride, sulphate and nitrate, and the test for calcium have been dropped from the 1900 Pharmacopœia, since these impurities are innocuous, and the use of caustic soda is more technical than medicinal.

Action and Uses.—The applications of sodium hydroxide in medicine are the same as of Potassium Hydroxide (which see).

SODII HYPOPHOSPHIS, *U. S., Br.*—Sodium Hypophosphite.

Natrium hypophosphorosum. — *Hypophosphite de soude,* Fr.; *Unterphosphorigsaures Natron,* G.

Formula, $NaPH_2O_2 + H_2O$. Molecular weight, 105.29.

It should contain not less than 98 per cent. of the pure salt, and be kept in well-stoppered bottles. Also *caution should be observed* in handling, as explosion is liable to

occur when triturated or heated with nitrates, chlorates, or other oxidizing agents. —U. S.

Preparation.—An aqueous solution of 6 parts of calcium hypophosphite is accurately precipitated by a solution of 10 parts of crystallized sodium carbonate; insoluble calcium carbonate and soluble sodium hypophosphite are produced, and separated by filtration; on evaporating the filtrate, the latter salt is left behind, and if necessary may be freed from sodium carbonate by redissolving it in alcohol, filtering, and evaporating.

Properties.—Sodium hypophosphite is usually obtained in the form of a white granular powder, but by the slow evaporation of its alcoholic solution may be procured in pearly rectangular, tabular crystals, which, when dried over sulphuric acid and afterward heated to about 115° C. (239° F.), lose nearly 17 per cent. of water. Above 200° C. (392° F.) spontaneously inflammable hydrogen phosphide is evolved, and a porous mixture of sodium pyrophosphate and metaphosphate, sometimes mingled with a little red phosphorus, is left. The salt is inodorous, has a peculiar bitterish-sweet saline taste, is deliquescent in the air, though less so than potassium hypophosphite, and is easily soluble in water, slightly in absolute alcohol, but is insoluble in ether. The U. S. P. states it to be soluble in 1 part of water and in 25 parts of alcohol at 25° C. (77° F.), in 0.12 part of boiling water, and in 1 part of boiling alcohol. A fragment of the salt imparts to a non-luminous flame an intense yellow color. The aqueous solution, slightly acidulated with diluted sulphuric acid, yields with test-solution of silver nitrate a white precipitate, which rapidly turns brown and black, owing to the separation of metallic silver; and when acidulated with hydrochloric acid and added to excess of test-solution of mercuric chloride, it first produces a white precipitate of calomel, and on further addition metallic mercury separates. With copper sulphate test-solution, on gentle heating, a reddish-brown precipitate of copper hydride is formed, which readily decomposes with effervescence into copper and hydrogen. When evaporated with dilute nitric acid and finally ignited, a residue is obtained weighing 97 per cent. of the weight of the hypophosphite, and consisting of sodium metaphosphate. Like all hypophosphites, the salt is oxidized on exposure to the air to phosphite and phosphate, and must therefore be preserved in well-stoppered bottles.

The U. S. P. salt is represented as hydrated, while that of the Br. is anhydrous. The salt found in European and American markets is almost anhydrous. According to Jowett (*Pharm. Journ.*, August 13, 1898), sodium hypophosphite can be completely dehydrated without change by heating at 110° C. (230° F.) to constant weight, and it is not altered in any way when boiled in air-free water.

Tests.—The aqueous solution of the salt (1 in 20) should not be colored red by the addition of a drop of phenolphthalein test-solution, nor effervesce on the addition of an acid (absence of caustic alkali or carbonate). In the aqueous solution (1 in 20), acidulated with hydrochloric acid, an equal volume of hydrogen sulphide test-solution should not produce any turbidity or coloration after standing corked at 35° C. (95° F.) for at least half an hour, either before or after the addition of ammonia-water to slight excess (absence of arsenic, lead, etc.), 5 Cc. of the aqueous solution of the salt (1 in 10) when measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water and evaporated to dryness on a bath of boiling water, should not respond to the modified Gutzeit's test for arsenic, given under Arseni Trioxidum. The U. S. P., 1900, has omitted the assay of the salt, since all volumetric methods are defective and the gravimetric methods, which are alone accurate, are not suitable for pharmacists. The permanganate method of titration of the previous pharmacopœia is defective, and has been criticised by Jowett, who has made a comparative study of various methods (see under Calcium Hypophosphite). Any phosphite present would also react with permanganate, and thus vitiate the result. This may be detected by solution of lead acetate which precipitates lead phosphite. Phosphate would also be precipitated in the same way, but this is not likely to be present, while phosphite is almost always present in the commercial hypophosphites.

The Br. P. requires that a solution of the salt give little or no precipitate with lead acetate (limit of phosphate and phosphite), and that 0.5 Gm. of the salt, boiled 10 minutes with 25 Cc. of water and 1.15 Gm. of potassium permanganate, give a nearly colorless filtrate, showing complete reduction. As 3 molecules of the salt require 4 molecules of the permanganate for reaction, 1.15 Gm. of $KMnO_4$ represents 0.4808 Gm. of hypophosphite, which corresponds to 96.16 per cent. purity. The criticism above also

applies to this method of assay. The U. S. P., 1900, has omitted tests for sulphate, chloride, calcium and limit of phosphate and potassium.

Action and Uses.—The properties of sodium hypophosphite are similar to those possessed by the hypophosphites in general (see CALCII HYPOPHOSPHIS). The dose is from 5 to 20 grains (0.30–1.30 Gm.).

SODII IODIDUM, *U. S., Br.*—Sodium Iodide.

Natrium iodatum, P. G.—*Iodure de sodium*, Fr.; *Jodnatrium*, G.

Formula, NaI. Molecular weight, 148.78.

It should be kept in well-stoppered bottles and should contain not less than 98 per cent. of the pure salt.—U. S.

Preparation.—This salt may be obtained by processes analogous to those which afford potassium iodide, either from iodine and solution of caustic soda or by decomposing a solution of iodide of iron with sodium carbonate. The latter process is the more profitable one, since on the reduction of sodium iodate by charcoal a portion of the salt is converted into sodium carbonate.

Properties.—When crystallized at a temperature above 40° C. (104° F.), anhydrous sodium iodide is obtained in cubes which are deliquescent on exposure and should therefore be kept in well-stoppered bottles. This salt melts at a dull-red heat, and when fused in contact with the air parts with a little iodine, at a higher temperature volatilizes slowly, but more readily than the chloride, and on cooling congeals to a pearly radiating crystalline mass. At ordinary temperatures the solution yields short monoclinic prisms or plates which have the composition $NaI.2H_2O$ and the molecular weight 184.54, effloresce in dry air, on exposure are deliquescent, melt at a moderate heat in the water of crystallization, and become anhydrous. The salt is usually prepared by evaporation to dryness in the form of a white crystalline powder, which is inodorous, of a saline, somewhat sharp and bitterish taste, and has a faint alkaline reaction. According to the U. S. P., 1 part of the official salt dissolves at 25° C. (77° F.) in 0.5 part of water, and in about 3 parts of alcohol; in 0.33 part of boiling water, and in 1.4 parts of boiling alcohol. The salt is also soluble in glycerin. It differs from potassium iodide in not being precipitated from its concentrated aqueous solution by a concentrated solution of sodium bitartrate, and in imparting a yellow color to flame, which on being observed through a blue glass should not, or only transiently, appear red. On adding a little chlorine-water to the aqueous solution and agitating it with chloroform or carbon disulphide, these liquids will acquire a violet color. Sodium iodide, as well as its aqueous solution, gradually undergoes decomposition upon exposure to light, becoming colored from free iodine, hence both should be preserved in dark amber-colored bottles. A very marked development of heat takes place when strong solutions of the anhydrous salt are made, due to a chemical union of the salt with water, whereas similar solutions of potassium iodide produce a decided reduction of temperature.

Tests.—If the salt be in distinct crystals, only few monoclinic prisms (containing 2 molecules of water) should be found among the regular cubes of the anhydrous salt. A solution of 1 Gm. of the salt in 1 Cc. of water should not yield any precipitate with 1 Cc. of sodium bitartrate test-solution (limit of potassium). If 1 Gm. of the salt be dissolved in water, and 0.1 Cc. (2 drops) of tenth-normal sulphuric acid solution be added, no red color should be produced by the addition of a drop of phenolphthalein test-solution, even after heating (limit of alkali). The aqueous solution (1 in 20) of the salt, slightly acidulated with hydrochloric acid, should not be colored or rendered turbid by addition of an equal volume of hydrogen sulphide solution and allowing to stand corked in a warm place for ½ hour, either before or after adding ammonia-water to slight excess (absence of heavy metals). If 0.5 Gm. of the salt be dissolved in 10 Cc. of previously boiled and cooled distilled water, no distinct yellow tint should be visible (absence of free iodine), nor should the solution acquire a yellow color within ½ minute after adding 2 drops of diluted sulphuric acid free from sulphurous or nitrous acid (limit of iodate). If 5 Cc. of the aqueous solution be gently heated with 1 drop of ferrous sulphate test-solution and 0.5 Cc. of potassium hydroxide test-solution, no blue color should appear after acidulating the mixture with hydrochloric acid (absence of cyanide). If 1 Gm. of the salt, 5 Cc. of water, 5 Cc. of potassium hydroxide test-solution, and about 0.2 Gm. of aluminum wire, contained in a 40 Cc. test-tube having a pledget of purified cotton in its

upper part and a piece of moistened red litmus-paper over its mouth, be heated upon a water-bath for 15 minutes, no blue coloration of the paper should be discernible (limit of nitrates and nitrites). 10 Cc. of the aqueous solution (1 in 20), when acidulated with hydrochloric acid, should not be made turbid by the addition of 1 Cc. potassium sulphate test-solution (absence of barium).

0.2 Gm. of the salt in 2 Cc. of ammonia-water, thoroughly shaken with 15 Cc. of tenth-normal silver nitrate solution, should give a filtrate which, upon acidifying with nitric acid, does not become more than slightly turbid (limit of chloride and bromide), nor show any darkening within 10 minutes (absence of thiosulphate). This test is identical with that of the P. G., which also adds that an *opaque* filtrate indicates more than 1 per cent. of sodium chloride. 0.5 Gm. of the well-dried salt dissolved in 10 Cc. of distilled water, to which about 5 drops of potassium chromate test-solution are added, should require not more than 34.6 Cc. nor less than 33 Cc. of tenth-normal silver nitrate solution to produce a red color (corresponding to at least 98 per cent. of pure sodium iodide).—U. S. Each Cc. of the silver solution represents 0.01488 Gm. of pure NaI, hence 0.5 Gm. of pure NaI would require 33.6 Cc. of the silver solution for titration. The lower limit, 33 Cc., allowed, represents 0.49 Gm. of pure bromide, or 98 per cent. Chloride, the most likely impurity present having an effect on silver solution, would tend to throw the titration figure higher than the theoretical quantity of silver solution required for pure sodium bromide. Each 0.525 Cc. of silver solution consumed in excess of the theoretical quantity, represents 1 per cent. of NaCl, assuming this to be the impurity; hence 1 Cc. (34.6–33.6) excess represents 1.9 per cent. of NaCl as impurity. The comments made under Potassii Iodidum as to the errors involved in the titration apply also to sodium iodide.

The Br. P. demands that 1 Gm. of the dried salt require not less than 66.5 Cc. of tenth-normal silver nitrate for titration. The quantity for a pure salt would be 67.21 Cc. The figure 66.5 corresponds to 98.96 per cent. of NaBr.

The U. S. P., 1900, has dropped tests for calcium, limit of sulphate, and for iron by the ferrocyanide method.

Action and Uses.—The indications for the employment of sodium iodide are the same as for potassium iodide. It is claimed that it is less liable to occasion skin eruptions, and is less depressing in large doses than potassium iodide. It is given in the dose of 10 to 40 grains (0.60–2.60 Gm.) or more. (See Potassii Iodidum.)

SODII NITRAS, *U. S.*—Sodium Nitrate.

Natrium nitricum, P. G.; *Nitrum cubicum.*—*Cubic niter, Chile saltpeter*, E.; *Azotate (Nitrate) de soude, Nitre cubique, Nitrate de Chili*, Fr.; *Natriumnitrat, Chilesalpeter*, G.

Formula $NaNO_3$. Molecular weight, 84.45.

It should be kept in well-stoppered bottles and should contain not less than 99 per cent. of the pure salt.—U. S.

A native salt, purified by crystallization from water.

Origin and Preparation.—Sodium nitrate was first observed by Bohn (1683) on distilling a mixture of table-salt and nitric acid, and was prepared by Marggraf (1761) from calcium nitrate and sodium sulphate. In 1820 it became known through Mariano de Rivero that it exists in immense quantities in certain districts of Chile and Peru, where it is imbedded in clay and sand and more or less mixed with sulphates and chlorides of sodium, calcium, and magnesium. The stratum containing this saline mass, which is called *caliche* or *terra salitrosa*, is blasted, the salt extracted by boiling with water, and the decanted solution crystallized. In this condition sodium nitrate is brought into the market in damp crystalline masses, which are more or less colored by intermixed earth and require to be purified by recrystallization.

Properties.—Purified sodium nitrate crystallizes in colorless, transparent rhombohedrons of the hexagonal system, which are permanent in dry, but slightly deliquescent in moist air, having a neutral reaction, and dissolve at 25° C. (77° F.) in 1.1 parts of water and in about 100 parts of alcohol (50 parts, P. G.), in 0.6 part of boiling water, and in 40 parts of boiling alcohol. When heated at 312° C. (593.6° F.) the salt melts without decomposition. At a higher temperature it evolves oxygen, and is reduced to nitrite. On red-hot charcoal it deflagrates, but the action is less intense than in the case of potassium nitrate. To a non-luminous flame it imparts an intensely

yellow color. The aqueous solution is neutral to litmus-paper. If the aqueous solution be mixed in a test-tube with a drop of diphenylamine test-solution, and sulphuric acid be carefully poured in, so as to form a separate layer, a deep blue color will appear at the zone of contact. The salt is inodorous and has a cooling, saline, and somewhat bitter taste. It is of comparatively little interest in pharmacy, but is extensively employed in the manufacture of nitric and sulphuric acids, potassium nitrate, etc. Unlike ordinary saltpeter, it is hygroscopic and more soluble in water and alcohol.

Tests.—The aqueous solution (5 per cent.) should remain unaffected by hydrogen sulphide and ammonium sulphide (absence of metals), also after addition of ammonia-water, by ammonium oxalate (calcium), or sodium phosphate solution (absence of magnesium).—P. G. If to 10 Cc. of the solution (1 in 20) 1 Cc. of chloroform be added, then chlorine-water, previously diluted with an equal volume of water, drop by drop, with agitation, the chloroform should be free from any violet color (absence of iodide). The aqueous solution (1 in 20) slightly acidified with hydrochloric acid, and mixed with an equal volume of hydrogen sulphide solution, should not become colored or turbid within ½ hour on standing corked in a warm place, either before or after adding ammonia-water in slight excess (absence of heavy metals, arsenic, etc.). —U. S. No turbidity should be produced within 5 minutes in the aqueous solution, acidulated with nitric acid, on the addition of either barium chloride test-solution (limit of sulphate) or silver nitrate test-solution (limit of chloride).—P. G. 1 Gm. of the salt, treated with an excess (or about 1 Cc.) of sulphuric acid and afterward heated to redness until vapors cease to be given off, yields a residue weighing .835 Gm. The U. S. P., 1900, has omitted the tests for chloride, sulphate, calcium, and potassium.

Action and Uses.—Sodium nitrate is rarely used in medicine. It has been proposed as a remedy in diarrhœa and dysentery in daily doses of from 1 to 2 ounces (30–60 Gm.).

SODII NITRIS, *U. S., Br.*—Sodium Nitrite.

Nitrite de soude, Fr.; *Salpetrigsaures Natron*, G.

Formula, $NaNO_2$. Molecular weight, 68.57.

It should be kept in well-stoppered bottles and should contain not less than 90 per cent. of the pure salt.—U. S.

Preparation.—When sodium nitrate is heated with charcoal, starch, or similar substances, sodium nitrite is formed, and may be recovered by lixiviation of the mass with water. A better process consists in adding to sodium nitrate, previously fused in shallow iron pans, about two and a half times its weight of lead, free from zinc and antimony, the lead fusing readily and being converted into yellow oxide or litharge. An excess of lead is used, and the fused mass is kept in constant agitation for about 4 hour; the fusion is continued for 3½ hours. After cooling the mass is lixiviated with water in large iron tanks, and when the solution has reached the specific gravity 1.342, it is treated with nitric acid specific gravity 1.029, and then concentrated to 1.414 specific gravity, clarified by rest, and set aside in lead-lined wooden tanks to crystallize. By repeated recrystallization the salt is obtained quite pure (98 per cent. and over).

Properties.—Sodium nitrite occurs in the form of white opaque pencils or colorless, transparent, hexagonal crystals, odorless, and having a mild saline taste. When exposed to the air the salt deliquesces, and is gradually oxidized to sodium nitrate; hence it should be kept in well-stoppered bottles. It is soluble in about 1.4 parts of water at 25° C. (77° F.), and very soluble in boiling water; slightly soluble in alcohol. The aqueous solution gives an alkaline reaction with litmus-paper, and when mixed with solution of ferrous sulphate and acetic acid becomes of a dark-brown color. If the aqueous solution of the salt be mixed with some potassium iodide test-solution and a few drops of an acid added, iodine will be liberated, and nitrogen dioxide gas will escape with effervescence, When heated the salt melts, and at a red heat it is decomposed, yielding oxygen, nitrogen, nitrogen dioxide, and sodium oxide. To a non-luminous flame it imparts an intensely yellow color.

Tests.—The salt should readily form a colorless solution with water, without leaving any insoluble residue. If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid, and heated sufficiently to expel the gases, the resulting solution, after restoring its original volume, when mixed with an equal volume of hydrogen sulphide

test-solution, should produce no coloration or precipitate after standing corked in a warm place for ½ hour, either before or after addition of ammonia-water to slight excess (absence of heavy metals). If to 30 Cc. of tenth-normal potassium permanganate solution, diluted with about 150 Cc. of distilled water, 5 Cc. of sulphuric acid, and 10 Cc. of a solution of 1 Gm. of sodium nitrite in sufficient water to make 100 Cc. be successively added, the liquid brought to a temperature of 40° C. (140° F.) and allowed to stand 5 minutes, not more than 3.75 Cc. of tenth-normal oxalic acid solution should be required to decolorize the solution (each Cc. of the permanganate solution consumed corresponding to 0.0034285 Gm. of pure $NaNO_2$).—U. S.

From the reaction, $5NaNO_2 + 2KMnO_4 + 3H_2SO_4 = 5NaNO_3 + K_2SO_4 + 2MnSO_4 + 3H_2O$, which takes place in the titration, this proportion is deduced, 2×156.98 Gm. $KMnO_4 : 5 \times 68.57$ Gm. $NaNO_3 :: 0.0031396$ Gm. $KMnO_4 : x$ Gm. $NaNO_2$, or $x =$ 0.0034285 Gm. $NaNO_2$. 1 Cc. of tenth-normal potassium permanganate solution contains 0.0031396 Gm. $KMnO_4$, hence 1 Cc. is equivalent to 0.0034285 Gm. $NaNO_2$. The volume of permanganate actually consumed by the nitrite is 30 Cc. —3.75 Cc. = 26.25 Cc., which represents 0.09 Gm. of pure $NaNO_2$ in 0.1 Gm. of the salt, or 90 per cent.

In the execution of the titration a better procedure is to add the nitrite solution to the permanganate first, and then follow with the sulphuric acid, as the possibility of loss of nitrogen trioxide gas when the nitrite strikes the surface of the acidified permanganate solution in the U. S. P. process is thus diminished.

The Br. P. employs the gasometric methed, which is like that of the U. S. P., 1890. If 0.1 Gm. of the salt be dissolved in 4 Cc. of water and introduced into a nitrometer filled with a concentrated solution of common salt, then followed successively by 0.7 Gm. of potassium iodide in 4 Cc. of water, and 10 Cc. of normal sulphuric acid, the liberated nitrogen dioxide gas should measure not less than 32.5 Cc. at 15.5° C. (60° F.) and 760 Mm. (30 inches) of mercury pressure, and should be almost completely soluble in a strong solution of ferrous sulphate.

The reaction which takes place, $NaNO_2 + KI + 2H_2SO_4 = NO + I + KHSO_4 + H_2O$, shows that 68.57 Gm. of $NaNO_2$ yields 29.81 Gm. of NO. 1 Cc. of NO at 15.5° C. and 760 Mm. of mercury pressure weighs 0.0012637 Gm., which represents 0.002907 Gm. of $NaNO_2$. Hence 32.5 Cc. required in the assay represents 0.09448 Gm. of $NaNO_2$, which is 94.48 (95) per cent. of 0.1 Gm. taken. In this calculation the correction which would be necessary for the pressure exerted by the water vapor in the gas is ignored, as it does not materially alter the results.

If the NO gas be measured at a temperature, t, and pressure, p, different from 15° C. and 760 Mm., the gas volume may be reduced to that which would be occupied under the latter conditions by the following formula, $x = \frac{V \times (273 + 15.5) \times p}{(273 + t) \times 760}$, where $V =$ the volume observed.

Action and Uses.—Sodium nitrite, like potassium nitrite, exerts the same influence upon the human organism as do nitroglycerin and amyl nitrite. On account of the slowness of its absorption and elimination, its effect is more prolonged. It is given in the dose of from 1 to 3 grains (0.06–0.20 Gm.).

SODII PHENOLSULPHONAS, *U. S.*—Sodium Phenolsulphonate.

Sodii sulphocarbolas, Br., U. S., 1890.—*Sodium sulphocarbolate, Sodium paraphenolsulphonate*, E.; *Sulphophénate de soude*, Fr.; *Phenolsulfosaures Natrium*, G.

Formula, $C_6H_4(OH)SO_3Na + 2H_2O$. Molecular weight, 230.45.

It should contain not less than 99 per cent. of pure Sodium Paraphenolsulphonate, and should be kept in well-stoppered bottles.—U. S.

Origin and Preparation.—If crystallized phenol is mixed with an equal weight of strong sulphuric acid, a new compound is formed, which was first noticed by Laurent (1841), and by him named phenylsulphuric acid, with the formula $C_6H_5HSO_4$. The true constitution of the new compound was shown by Kekulé to be phenolsulphonic acid, $HSO_3C_6H_4(OH)$, the group HSO_3 displacing an atom of H in the benzene nucleus, and not in the hydroxyl group, as formerly supposed. If the mixture of phenol and sulphuric acid be set aside in the cold for some time until it yields a clear solution with water, orthophenolsulphonic acid will be formed, but if the temperature be allowed to

rise or increase, various mixtures of the isomeric ortho- and para- varieties of the acid are obtained. In order to produce only the paraphenolsulphonic acid, the mixture is preferably heated on a boiling water-bath for 6 hours, when it will be found to yield a clear solution with water. After mixing the new acid compound with ten times its weight of water, an excess of barium carbonate is added, and the mixture kept at 100° C. (212° F.) until the acid has been neutralized; it is then filtered, and the solution of barium phenolsulphonate concentrated and mixed with sodium carbonate for mutual decomposition. $Ba(SO_3C_6H_4(OH))_2 + Na_2CO_3 = 2NaSO_3C_6H_4(OH) + BaCO_3$. The solution after filtration (to remove $BaCO_3$) is concentrated, and set aside to crystallize. In place of barium carbonate, lead carbonate may likewise be employed to neutralize the newly formed phenolsulphonic acid, as lead phenolsulphonate is also soluble in water.

Properties.—Sodium phenolsulphonate is in colorless, transparent, rhombic prisms, slightly efflorescent in dry air, odorless or nearly so, having a cooling, saline, somewhat bitter taste, and a neutral reaction; soluble in 4.8 parts of water and in about 130 parts of alcohol at 25° C. (77° F.), in 0.7 part of boiling water, and in 10 parts of boiling alcohol. When heated a little above 100° C. (212° F.) the salt loses its water (15.5 per cent.) and becomes white. At a higher temperature it emits inflammable vapors having the odor of phenol, and leaves a residue of sodium sulphate amounting to 30.6 per cent. of the original weight, the filtered solution of which, acidulated with nitric acid, produces a white precipitate with test-solution of barium chloride. A fragment of the salt imparts an intense yellow color to a non-luminous flame. The dilute, aqueous solution (1 in 100) of the salt is colored violet by test-solution of ferric chloride.—U. S. When fused together with potassium hydroxide, pyrocatechin is obtained.

Tests.—The aqueous solution (1 in 20), slightly acidulated and mixed with an equal volume of hydrogen sulphide solution, should not become colored or turbid when kept corked at 35° C. (95° F.) for ½ hour, either before or after adding ammonia-water in slight excess (absence of heavy metals, arsenic, etc.). The solution should remain clear with solution of barium chloride (absence of sulphate).—U. S. It does not give a yellowish-brown precipitate with uranium nitrate solution (distinction from salicylate).—Br.

Action and Uses.—The phenolsulphonates were introduced into medicine with the idea that when taken they would be decomposed in the body into phenol and sulphates, but experience has demonstrated the fallacy of this assumption. Even in massive doses they fail to produce the changes in the urine characteristic of phenol. Sodium phenolsulphonate in solution (3 to 5 grains (0.20–0.30 Gm.) to an ounce [30 Cc.]) forms a mildly antiseptic and astringent application for inflamed mucous membranes, and may be used with benefit in subacute and chronic urethritis, vaginitis, tonsillitis, otorrhœa, and rhinitis. Its employment as an intestinal antiseptic in fermentative indigestion and diarrhœa is rarely resorted to. Sodium phenolsulphonate is given in the dose of 3 to 15 grains (0.20–1 Gm.).

SODII PHOSPHAS, *U. S.*, *Br.*—Sodium Phosphate.

Natrium phosphoricum, P. G.—*Sodium orthophosphate, Disodium hydrogen phosphate*, E.; *Phosphate de soude*, Fr.; *Natriumphosphat, Phosphorsaures Natron*, G.

Formula, $Na_2HPO_4 + 12H_2O$. Molecular weight, 355.61.

It should contain, in an uneffloresced condition, not less than 99 per cent. of the pure salt, and should be kept in well-stoppered bottles, in a cool place.—U. S.

Origin.—Sodium phosphate exists in the urine of carnivorous animals and in other animal liquids. It was probably known to the ancients since the *chrysocolla* used for soldering (see Sodii Boras) was at least partly obtained from urine. Hellot (1735) recognized it as distinct from the ammoniacal salts of urine, and Haupt (1740) named it *sal mirabile perlatum*, because it melts before the blowpipe to an opaque pearly bead. Proust (1775) stated it to be a compound of soda, and Klaproth and Sheele (1785) proved also the presence of phosphoric acid. The salt was employed medicinally by Pearson (1787), and was usually prepared by neutralizing phosphoric acid with sodium carbonate; but at present it is exclusively prepared from bone phosphate.

Preparation.—There is no official method given in any of the pharmacopœias, and it is not practicable for the pharmacist to prepare the salt on a small scale. The mate-

rial that serves as the starting point for the manufacture of the salt is bone ash, or the ash obtained by calcining bones, which is principally tricalcium phosphate, together with small quantities of calcium carbonate, sodium chloride, magnesia, and silica. 10 parts of bone ash are digested with 8½ parts (6.66 parts, Berzelius) of concentrated sulphuric acid, diluted with 50 parts of water, for several days. $Ca_3(PO_4)_2 + 2H_2SO_4 = CaSO_4 + Ca(H_2PO_4)_2$. Insoluble calcium sulphate is formed, and soluble mono-calcium phosphate. The mass is thrown on a filter and washed with hot water. The filtrate is concentrated and set aside to allow the small quantity of calcium sulphate which separates to subside, refiltered, diluted, and heated. The hot solution is treated with a solution of sodium carbonate until precipitation ceases, set aside for a day in a warm place, filtered and concentrated to a point where crystals will form when nearly cold. The salt is further purified by recrystallization, and it should be borne in mind that the crystals formed in a warm solution, 35° C. (95° F.), or above, have not the same amount of water of crystallization as the official salt, but have the composition $Na_2HPO_4.7H_2O$. Moreover, the salt crystallizes best from a solution which is slightly alkaline, to secure which it is well to add a little sodium carbonate. The reaction taking place on adding sodium carbonate above is, $Ca(H_2PO_4)_2 + Na_2CO_3 = CaHPO_4 + Na_2HPO_4 + CO_2 + H_2O$. Part of the phosphoric acid is reprecipitated as insoluble secondary calcium phosphate, while sodium phosphate remains in solution, together with a little sulphate and chloride, which latter are gotten rid of by crystallization.

Properties.—The official sodium phosphate contains 60.3 per cent. of water of crystallization, a portion of which, 5 molecules or 25.1 per cent., is lost by efflorescence upon exposure to air; moreover, carbon dioxide is gradually absorbed, the salt being converted into monosodium phosphate and acid sodium carbonate; hence it must be preserved in well-stoppered bottles, in a cool place. At the temperature of boiling water the salt can be made anhydrous; but when exposed in this condition it again absorbs water, gradually forming a salt of the composition $Na_2HPO_4 + 7H_2O$, containing about 47 per cent. of water, which is permanent. Dried, granulated sodium phosphate occurs as an article of commerce, and is adopted in the U. S. P., 1900; it contains, weight for weight, a much larger proportion of Na_2HPO_4 than the official salt.

It crystallizes in colorless, transparent, obliquely four-sided, monoclinic prisms, which have the specific gravity 1.55, react slighly alkaline upon litmus-paper and phenolphthalein paper, are inodorous, and have a cooling saline taste. The crystals melt to a colorless liquid at 35° C. (95° F.) (Kopp), 40° C. (104° F.) (U. S., P. G.), and congeal on cooling to a crystalline mass. At a red heat the basylous water is expelled and sodium pyrophosphate is left. Crystallized sodium phosphate requires for solution 5.5 parts of water at 25° C. (77° F.) and less than 1.5 parts of boiling water. Sodium phosphate is insoluble in alcohol, and imparts a yellow color to flame, which, if observed through a blue glass, is not red, or only transiently so. The aqueous solution gives with silver nitrate a yellow precipitate, Ag_3PO_4, soluble in nitric acid and in ammonia; with magnesia mixture, a white precipitate soluble in acetic acid; and with ferric chloride, a white precipitate insoluble in acetic acid. If 0.5 Cc. of the aqueous solution be mixed with 1 Cc. of ammonium molybdate test-solution, the mixture will at once assume a yellow color, and, after a few minutes, yield a yellow precipitate of ammonium phospho-molybdate, the appearance of which is hastened by a gentle heat.

Tests.—No residue should be left on dissolving the salt in water (absence of calcium, etc.). No turbidity or coloration should be produced in the aqueous solution (1 in 20) by the addition of a small quantity of ammonium sulphide test-solution, or of an equal volume of hydrogen sulphide test-solution after addition of a few drops of hydrochloric acid and allowing to stand corked in a warm place for ½ hour (absence of metallic impurities). If 1 Gm. of the powdered anhydrous salt be shaken with 3 Cc. of stannous chloride test-solution, no brown coloration should appear within 1 hour (limit of arsenic).—P. G. No effervescence should occur on the addition of hydrochloric or nitric acid to a solution of the salt (absence of carbonate). On adding to 5 Cc. of the aqueous solution (1 in 20) 0.5 Cc. of silver nitrate test-solution, a pure yellow precipitate will be formed, which should not become dark colored by heating (absence of thiosulphate, etc.). 5 Cc. of the aqueous solution (1 in 10) should not respond to the modified Gutzeit's test for arsenic, described under ARSENI TRIOXIDUM. The U. S. P., 1900, has omitted the tests for chloride and sulphate. The Br. P. and P. G. permit only traces of these impurities.

Action and Uses.—Sodium phosphate in moderate doses is laxative, and in large doses a mild saline purge, resembling magnesium sulphate in its action. Rutherford and Vignal ascribe to it a stimulant effect upon the liver cells, and Bartholow considered it the best remedy in hepatic cirrhosis and catarrhal jaundice. The good that results from its administration in the latter condition is probably due to its action upon the catarrhal inflammation of the duodenum. Taken in quantity too small to loosen the bowels, it is absorbed into the blood, the alkalinity of which it slightly increases, and is supposed by some to combine with any excess of uric acid present and form soluble urates, which are readily eliminated. Sodium phosphate may be employed whenever a gentle laxative effect is desired. On account of its not unpleasant saline taste it is readily taken by children. It is particularly useful in those cases of alternate diarrhœa and constipation in bottle-fed infants, dependent upon a deficient flow of bile into the intestine. 2 to 4 grains (0.12–0.25 Gm.) of the salt should be dissolved in the milk at each feeding. Sodium phosphate is sometimes used on theoretical grounds in rickets and scrofulosis. The laxative dose ranges from ½ to 2 drachms (2–8 Gm.) 1 to 3 times a day. 1 to 2 ounces (30–60 Gm.) will produce purgation.

Allied Salt.—Sodii et Ammonii Phosphas, $NH_4NaHPO_4 + 4H_2O$. Molecular weight, 207.62. This is the *microcosmic salt* of the alchemists, and was formerly prepared from urine. It is obtained by dissolving 5 parts of crystallized sodium phosphate and 2 parts of ammonium phosphate in 20 parts of hot water, adding a little ammonia until the liquid is alkaline, and crystallizing. The salt crystallizes in colorless, transparent, monoclinic prisms which are inodorous and have a cooling saline taste, and a neutral or faint alkaline reaction. It effloresces superficially on exposure, losing a little ammonia, melts readily to a colorless liquid in its water of crystallization, and at a red heat forms a colorless glass of sodium metaphosphate, which is used in blowpipe analysis.

SODII PHOSPHAS EFFERVESCENS, *U. S.*, *Br.*—Effervescent Sodium Phosphate.

Natrium phosphoricum effervescens.—Phosphate de soude effervescent, Fr.; *Brausendes Natriumphosphat*, G.

Preparation.—Exsiccated sodium phosphate, in fine powder, 200 Gm.; sodium bicarbonate, dried and powdered, 477 Gm.; tartaric acid, dried and powdered, 252 Gm.; citric acid, uneffloresced crystals, 162 Gm. To make about 1000 Gm. Powder the citric acid and mix it intimately with the exsiccated sodium phosphate and tartaric acid, then thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.). When the mixture, by the aid of careful manipulation with a wooden spatula, has acquired a moist consistence, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles.—U. S.

The formula of the Br. P. is as follows: Dry 25 ounces of crystallized sodium phosphate until it has lost 60 per cent. of its weight; powder the product, and mix with sodium bicarbonate 25 ounces, tartaric acid, in powder, 13½ ounces, and citric acid, in powder, 9 ounces. Place the mixture in a dish heated to 93.3° to 104.4° C. (200°–220° F.), and when the particles of the powder begin to aggregate, stir them assiduously until they assume a granular form; by means of sieves separate the granules of uniform size, and dry them at a temperature not exceeding 54.4° C. (130° F.). The final product should weigh about 50 ounces. Keep in well-closed bottles. The Br. preparation contains the same per cent. of phosphate as that of the U. S., but employs 4.82 per cent. more of sodium bicarbonate, 7.14 per cent. more of tartaric acid, and 11.11 per cent. more of citric acid, the quantities being in the order given, 500, 500, 270, 180 Gm.

Action and Uses.—Although an elegant pharmaceutical preparation, effervescent sodium phosphate presents no advantage over the salt in substance. It is largely used by the laity as a laxative in the dose of 1 to 4 drachms (4–16 Gm.), taken in about 4 ounces (160 Cc.) of water, usually before breakfast.

SODII PHOSPHAS EXSICCATUS, *U. S.*—Exsiccated Sodium Phosphate.

Natrium phosphoricum exsiccatum. — *Dried (anhydrous) sodium phosphate,* E.; *Phosphate de soude desséché,* Fr.; *Getrocknetes Natriumphosphat,* G.

It should contain not less than 99 per cent. of pure anhydrous sodium phosphate, Na_2HPO_4, and should be kept in well-stoppered bottles.—U. S.

Preparation.—Allow a convenient quantity of crystallized sodium phosphate to effloresce for several days in warm air, at a temperature of from 25° to 30° C. (77°–86° F.), then continue the drying in an oven, raising the temperature very gradually until 100° C. (212° F.) has been reached, and maintaining it until the salt ceases to lose weight. Powder and sift the residue and keep in bottles.—U. S.

The dried salt represents practically 40 (39.7) per cent. of the weight of the crystallized salt employed. It was introduced in the U. S., 1900, being a white powder which absorbs moisture readily, and conforms to the reactions and tests given under SODII PHOSPHAS.

Action and Uses.—The uses of exsiccated sodium phosphate are the same as of the hydrous salt. Since it is about 2½ times stronger than the ordinary phosphate, its dose is proportionately smaller. 10 to 60 grains (0.60–4 Gm.) will produce a laxative effect.

SODII PYROPHOSPHAS, *U. S.*—Sodium Pyrophosphate.

Natrium pyrophosphoricum.—*Pyrophosphate de soude,* Fr.; *Natriumpyrophosphat,* G.

Formula, $Na_4P_2O_7 + 10H_2O$. Molecular weight, 443.02.

It should contain in an uneffloresced condition not less than 99 per cent. of the pure salt, and be kept in well-stoppered bottles.—U. S.

Preparation.—10 ounces of crystallized sodium phosphate are exposed to a warm atmosphere until effloresced, and then heated to dull redness until a small portion of the mass, dissolved in water, causes with silver nitrate a white precipitate free from yellow tint. The white salt is dissolved in 5 pints of boiling water and the solution filtered if necessary and crystallized. The total yield will be 6 ounces.

When sodium phosphate is heated to a gradually increased temperature, it first undergoes fusion at about 44° C. (111.2° F.), at 100° C. (212° F.) loses all of its water of crystallization (60.31 per cent.), and finally at 300° C. (572° F.) is converted into sodium pyrophosphate, two molecules of the official phosphate yielding one molecule of anhydrous pyrophosphate, thus $2Na_2HPO_4.12H_2O = Na_4P_2O_7 + 25H_2O$.

Properties.—The salt crystallizes in colorless or whitish transparent or translucent monoclinic prisms or plates which are inodorous and have a cooling saline and feebly alkaline taste. It is permanent in cool air, slightly efflorescent in warm air. Soluble in 11.5 parts of water at 25° C. (77° F.), and in 1.1 parts of boiling water; insoluble in alcohol. When heated to 100° C. (212° F.), the salt loses its water of crystallization (40.35 per cent.) without previous fusion. At a higher temperature it fuses, forming a transparent liquid, which, on cooling, solidifies to a crystalline mass. To a non-luminous flame it imparts an intensely yellow color. Its aqueous solution is feebly alkaline to litmus and to phenolphthalein paper. A 5 per cent. aqueous solution of the salt yields, with magnesia mixture, a white precipitate; with silver nitrate test-solution it yields a precipitate of a pure white color (distinction from orthophosphate), soluble in ammonia water, and in nitric acid without effervescence (absence of carbonate). With ammonium molybdate test-solution no precipitate is formed within 15 or 20 minutes, even when a gentle heat is applied (distinction from orthophosphate). On boiling the aqueous solution with free mineral acids the salt is gradually converted into orthophosphate.

Tests.—The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid and mixed with an equal volume of hydrogen sulphide solution, should not become colored or turbid on standing corked at 35° C. (95° F.) for half an hour, either before or after addition of ammonia water in slight excess (absence of heavy metals). 5 Cc. of the aqueous solution (1 in 10) should not respond to the modified Gutzeit test for arsenic given under ARSENI TRIOXIDUM. The U. S. P., 1900, has dropped the tests for chloride, sulphate, and potassium in this salt.

Uses.—It is said that the action and uses of this salt are the same as those of sodium phosphate, but that it should be given in doses one-third less. Its pharmaceutical uses give it its chief value. The crystals are difficult to reduce to fine powder, and are far less soluble in water than those of the orthophosphate.

SODII SALICYLAS, *U. S., Br.*—Sodium Salicylate.

Natrium salicylicum, P. G.—*Salicylate de soude*, Fr.; *Natriumsalicylat, Salicylsaures Natrium*, G.

Formula, $NaC_7H_5O_3$. Molecular weight, 158.89.

It should be kept in well-stoppered bottles, protected from heat and light, and should contain not less than 99.5 per cent. of the pure salt.—U. S.

Preparation.—Sodium bicarbonate 10 parts and salicylic acid 16.5 parts are mixed in a porcelain or glass vessel, and 10 parts of pure water are gradually added: as the reaction progresses carbon dioxide is rapidly evolved, the newly formed salt remaining in solution, which latter should have a slightly acid reaction to ensure a product free from color. If necessary, the solution may receive a slight addition of salicylic acid, as alkali salicylates in the presence of an excess of alkali absorb oxygen from the air and become colored. The solution is heated on a water-bath to expel all carbon dioxide, and then evaporated at about 60° C. (140° F.) to dryness; the residue may be recrystallized from a solution in 120 parts of 95 per cent. alcohol if desired. Owing to the delicate reaction of salicylic acid with iron salts, all contact with metals must be avoided; moreover, the salicylic acid must be free from creosotic (homosalicylic) acid, and the alkali free from iron.

Although not a bibasic acid, salicylic acid is capable of forming two classes of salts, primary and secondary salicylates; the former are obtained when the acid is neutralized by means of alkali carbonates or bicarbonates, whereas the use of alkali hydroxides results in the formation of the secondary salts, which are less soluble and less stable.

The official sodium salicylate of the U. S., G., and Br. Pharmacopœias is the primary salt, the first two named recognizing the anhydrous salt, while the latter admits 5.3 per cent. of water, the salt having the composition $2NaC_7H_5O_3 + H_2O$.

Properties.—Sodium salicylate is a white micro-crystalline powder or forms small white crystalline scales, is permanent in the air, inodorous or nearly so, and has a sweetish saline and mildly alkaline taste and a feebly acid reaction. It dissolves at 25° C. (77° F.) in 0.8 part of water and in 5.5 parts of alcohol, and is more freely soluble in boiling water and boiling alcohol; also soluble in glycerin. By heat the salt is decomposed, inflammable vapors and an odor of phenol are given off, and a carbonaceous residue of sodium carbonate is left, weighing about 33 per cent. of the salt used, and imparting to a non-luminous flame an intense yellow color. If copper sulphate test-solution be added to the aqueous solution (1 in 20), a green color will be produced. On adding to a small portion of the salt, in a test-tube, about 1 Cc. of concentrated sulphuric acid, and then, cautiously, about 1 Cc. of methylic alcohol in drops, on heating the mixture to boiling the odor of methyl salicylate will be evolved. Ferric chloride added to the concentrated aqueous solution of the salt produces a violet precipitate, but a very diluted solution (1 in 100) is colored violet. The rather concentrated aqueous solution, when strongly acidulated with hydrochloric or sulphuric acid, gives a white crystalline precipitate, which is soluble in ether and in hot water and has all the properties of salicylic acid (which see).

Tests.—The aqueous solution should be colorless, and should slightly redden blue litmus-paper (absence of carbonate). Agitated with about 15 parts of concentrated sulphuric acid, the salt should not impart color to the acid (absence of foreign organic matter).—Br., P. G. If a solution of 1 Gm. of the salt in a mixture of 50 Cc. of alcohol and 25 Cc. of water be acidulated with nitric acid, the filtered solution should yield no precipitate, nor be rendered turbid on the addition of a few drops of test-solution of barium chloride (absence of sulphate) or of silver nitrate (absence of chloride). —Br. P., P. G. In the last test the addition of alcohol is made for the purpose of keeping in solution the salicylic acid liberated by the nitric acid, whereby filtration is avoided. The salt should not have the odor of phenol. If to an aqueous solution of the salt (1 in 20) 3 drops of iodine solution and a slight excess of hydrochloric acid be added, the filtrate should not yield a precipitate upon adding barium chloride solution (absence of sulphite). If sulphite were present, the iodine would oxidize it to sulphate. If the aqueous solution (1 in 20) be acidulated with hydrochloric acid and the precipitated salicylic acid filtered off, the filtrate, mixed with an equal volume of hydrogen sulphide solution, should not become colored or turbid on standing corked at 35° C. (95° F.) for half an hour, before or after addition of ammonia in slight excess (absence of heavy

metals, arsenic, etc.). If 1 Gm. of the dry salt be thoroughly ignited at red heat, and the residue be repeatedly extracted with hot water, filtered, and well washed, the cold filtrate should require for complete neutralization not less than 12.52 Cc. of half-normal sulphuric acid, methyl orange being the indicator, corresponding to 99.5 per cent. purity. Each Cc. of the acid is equivalent to 0.079445 Gm. of the salt when incinerated and converted into carbonate.—U. S. In a solution of the salt containing not less than 1 per cent., uranium nitrate solution produces a yellowish-brown precipitate (distinction from carbolates and sulphocarbolates).—Br.

Action and Uses.—The uses of sodium salicylate are identical with those of salicylic acid. On account of its greater solubility and less irritating action upon the stomach it is preferable to salicylic acid for internal administration. It is given in the dose of 5 to 30 grains (0.30–2 Gm.) every 3 or 4 hours. (See ACIDUM SALICYLICUM.)

Allied Salts.—SODIUM DIIODOSALICYLATE. $NaC_6H_2I_2(OH)CO_2 + 2.5H_2O$.—When an alcoholic solution of salicylic acid is treated with iodine and iodic acid, diiodosalicylic acid is formed by substitution of 2 atoms of iodine for 2 of hydrogen, which may be neutralized with sodium carbonate, and then yields white laminæ or long, flat, needle-shaped crystals which are soluble in 50 parts of water at 20° C. (68° F.). The salt possesses analgesic and antiseptic properties.

SODIUM DITHIOSALICYLATE.—*Dithion.* $[S.C_6H_3(OH)CO_2Na]_2$.—If a mixture of equal molecular weights of sulphur chloride (bromide or iodide) and salicylic acid is heated for some time to 120°–150° C. (248°–302° F.), a lively reaction ensues, hydrogen chloride (bromide or iodide) escaping, and dithiosalicylic acid remaining in the form of a yellowish resinous mass. The residue, which is soluble in alcohol, is a mixture of two isomeric acids, designated respectively as No. 1 and No. 2. When the acid is treated with solution of sodium carbonate, the two sodium salts are formed, and may be separated by means of sodium chloride, which precipitates the No. 1 salt, while the No. 2 salt remains in solution; or the dried mixture of the two salts may be exhausted with boiling alcohol, which dissolves only the No. 2 salt. This latter salt is preferred; it occurs as a grayish-white amorphous powder, very hygroscopic, and readily soluble in water, forming a brownish-black solution of alkaline reaction. Its antiseptic activity is superior to sodium salicylate, and it has been successfully employed in rheumatic fever, gonorrhœic rheumatism, and similar cases. The dose is from 4 to 10 Gm. daily in doses of 0.5 to 1 Gm. Sodium dithiosalicylate No. 1 is a yellowish amorphous powder, somewhat hygroscopic, and of alkaline reaction; it forms with water a clear brownish solution. The salt has been chiefly employed in veterinary practice, in the form of a 5 per cent. solution.

SODIUM SULPHOSALICYLATE. $C_6H_3(OH)CO_2HSO_3Na$. This salt, obtained by neutralizing sulphosalicylic acid with sodium carbonate, occurs in colorless crystals, soluble in 25 to 30 parts of water; the aqueous solution has an acid reaction, and is not affected by barium chloride or silver nitrate. The salt has been recommended as a substitute for sodium salicylate in the treatment of articular rheumatism.

SODIO-THEOBROMINE SALICYLATE.—*Diuretin.* $C_7H_7NaN_4O_2 + NaC_7H_5O_3$. This compound is obtained by mixing aqueous solutions of equal molecules of sodium theobromine and sodium salicylate and evaporating to dryness; a definite compound appears to be formed, containing theoretically 49.7 per cent. of theobromine and 38.1 per cent. of salicylic acid. Diuretin occurs as a white powder, odorless, of a saline, alkaline taste, and soluble in half its weight of warm water, the solution remaining perfect on cooling. It should be preserved in well-stoppered bottles, as it is readily affected by the air, theobromine separating by action of carbon dioxide, whereby it then fails to form a clear solution in water. Such a milky solution is easily cleared by adding a few drops of caustic soda solution. It has proved to be a reliable diuretic, free from poisonous properties and unpleasant after-effects. The daily dose of diuretin is 60 to 120 grains (4–8 Gm.) in divided portions of 15 grains (1 Gm.) each; it is best administered in solution with aromatic waters, and should not be dispensed in powder form, owing to liability to change upon exposure.

LITHIUM DIURETIN, *Uropherin*, is a corresponding lithium theobromine salicylate, made like the previous salt, but substituting lithium for sodium. It is a white powder, soluble in 5 parts of water, and given in doses of 15 grains (1 Gm.).

SODII SULPHAS, *U. S., Br.*—Sodium Sulphate.

Natrium sulphuricum, P. G.—*Glauber's Salt*, E.; *Sulfate de soude, Sel de Glauber*, Fr.; *Glaubersalz, Natriumsulfat*, G.

Formula, $Na_2SO_4 + 10H_2O$. Molecular weight, 319.91.

It should be kept in well-closed vessels, in a cool place, and should contain, in an uneffloresced condition, not less than 99 per cent. of the pure salt.—U. S.

Origin.—Sodium sulphate is found native in the anhydrous state and crystallized, and also in combination with calcium sulphate. It is present in the water of many mineral springs and in that of certain lakes in Russia and in the western part of the United States. It is stated to have been known in Saxony for a century before it was obtained artificially by Glauber (1658) from the saline residue left in the preparation of hydrochloric acid, and was named after him *Sal mirabile Glauberi.* The same salt, prepared from the mineral spring at Friedrichshall, became known in 1767 as *Sal. aperitivum Fridericianum.* It is largely manufactured in the United States, but small and variable quantities of it are also imported.

Preparation.—This salt is largely obtained in many chemical processes, either as an intermediate or a secondary product, as in the preparation of soda by Leblanc's process; from the mother-liquors of the Stassfurt potash-works; in the preparation of magnesium carbonate; in the manufacture of hydrochloric and nitric acids from sodium chloride and nitrate; in the preparation of table-salt from many saline springs; in the manufacture of sal ammoniac from ammonium sulphate and sodium chloride; in preparing carbon dioxide for the manufacture of mineral waters from sodium bicarbonate and sulphuric acid; and in several other processes. Sodium sulphate as thus obtained is purified by crystallizing it repeatedly from water, if necessary, after neutralization with sodium carbonate. Crystallized from water at or above 33° C. (91.4° F.), it has the composition $Na_2SO_4.7H_2O$.

Properties.—Sodium sulphate crystallizes in large, transparnt, ecolorless, monoclinic prisms, which are inodorous, have a cooling, saline, and distinctly bitter taste, and rapidly effloresce on exposure to the air, leaving a white powder. The crystallized salt must therefore be kept in well-stoppered bottles, and, on account of its low melting-point, in a cool place. It is soluble at 15° C. (59° F.) in 2.8 parts of water. The solubility increases up to 34° C. (93.2° F.), when its maximum is attained, 1 part of the salt then dissolving in 0.25 part of water; from thence it gradually decreases with rising temperature, until 1 part requires 0.47 part of boiling water for solution. Insoluble in alcohol; soluble in glycerin. When heated to 33° C. (91.4° F.), the salt fuses, and, on being heated to 100° C. (212° F.), loses all of its water (55.9 per cent.). At a red heat the anhydrous salt fuses without decomposition. To a non-luminous flame it imparts an intensely yellow color. The aqueous solution is neutral to litmus-paper. A 5 per cent. aqueous solution of the salt yields with barium chloride a white precipitate insoluble in nitric acid.

Tests.—If to 5 Cc. of the aqueous solution (1 in 20) 1 Cc. of sodium phosphate test-solution and 0.5 Cc. of ammonia water be added, no turbidity or precipitate should be produced, even after agitation (absence of magnesium). The aqueous solution (1 in 20), slightly acidulated and mixed with an equal volume of hydrogen sulphide solution, should not become colored or turbid on standing corked at 35° C. (95° F.) for half an hour, before or after adding ammonia water in slight excess (absence of heavy metals). 5 Cc. of the aqueous solution (1 in 10) should not respond to the modified Gutzeit's test for arsenic given under ARSENI TRIOXIDUM. 20 Cc. of the 5 per cent. solution should not be changed by addition of 0.5 Cc. of potassium ferrocyanide solution (absence of iron).—P. G. 100 grains of it, dissolved in distilled water and acidulated with hydrochloric acid, give, by the addition of barium chloride, a white precipitate which, after washing and drying, weighs 72.3 grains, or 1 Gm. yields 0.723 Gm. of $BaSO_4$ (0.725 Gm., Br.). The U. S. P., 1900, has omitted the tests for carbonate, calcium, magnesium, ammonium salt, and chloride, all of which are retained in the Br. P. The Br. P. and P. G. allow only mere traces of chloride.

SODII SULPHAS EXSICCATUS, s. *Natrium sulfuricum siccum,* P. G.—*Dried sodium sulphate,* E.; *Getrocknetes Natriumsulfat,* G. It is obtained by exposing the crystallized salt to a moderate heat until its weight has been reduced to one-half, when the white powder is passed through a sieve and preserved in well-stoppered bottles. This form is convenient in dispensing, and represents double the weight of the crystallized salt.

Action and Uses.—Sodium sulphate is a hydrogogue cathartic, resembling in its action other members of this group, and, like them, is more efficacious when given in concentrated solution. Because of its nauseous taste and drastic action it has been supplanted in this country and England by magnesium sulphate. It is the principal ingredient of many natural purgative waters, as Hunyadi, Carlsbad, Apenta, etc. Sodium sulphate and these waters are useful to overcome acute constipation from any cause, and

produces good results in the chronic form due to hepatic torpor and intestinal indigestion. Its purgative effect is of advantage in many febrile affections. The purgative dose of sodium sulphate is from ½ to 1 ounce (16–30 Gm.) dissolved in from 3 to 6 ounces (90–180 Cc.) of hot water, and taken, as a rule, ½ hour before breakfast. Its disagreeable taste may be partially masked by the addition of lemon juice or aromatic sulphuric acid.

SODII SULPHAS EFFERVESCENS, *Br.*—Effervescent Sodium Sulphate.

Natrium sulfuricum effervescence.—Brausendes Natriumsulfat, G.

Preparation.—Dry 25 ounces of crystallized sodium sulphate until it has lost 56 per cent. of its weight; powder the product and mix it with sodium bicarbonate 25 ounces, tartaric acid 13½ ounces, and citric acid, in powder, 9 ounces. Place the mixture in a dish heated to 93.3° to 104.4° C. (200°–220° F.), and when the particles of the powder begin to aggregate, stir them assiduously until they assume a granular form; by means of sieves separate the granules of uniform size, dry at a temperature not above 54.4° C. (130° F.), and preserve in well-closed bottles. The final product should weigh about 50 ounces, and contains about 22 per cent. anhydrous sulphate.

SODII SULPHIS, *U. S., Br.*—Sodium Sulphite.

Natrium sulfurosum.—Sulfite de soude, Fr.; *Natriumsulfit, Schwefligsaures Natron*, G.

Formula, $Na_2SO_3 + 7H_2O$. Molecular weight, 250.39.

It should be kept in well-stoppered bottles in a cool place, and should contain, in the uneffloresced and air-dried condition, not less than 96 per cent. of the pure salt.—U. S.

Preparation.—This salt is formed on passing sulphur dioxide into a solution of sodium carbonate until the color of blue litmus-paper is changed to red, or the solution of a known quantity of sodium carbonate is completely saturated with sulphur dioxide, whereby sodium bisulphite is produced; an equal weight of sodium carbonate is dissolved in the liquid, and the solution evaporated to crystallization. The sulphur dioxide decomposes the sodium carbonate, replacing the carbon dioxide which is evolved: $Na_2CO_3 + SO_2$ yields $Na_2SO_3 + CO_2$.

Properties.—Sodium sulphite crystallizes in colorless, transparent, monoclinic prisms, which are inodorous, and have a slight alkaline reaction to test-paper, and a cooling, saline, and sulphurous taste. The salt effloresces on exposure, and becomes opaque from the loss of water and from oxidation to sulphate, and therefore requires to be kept in well-stoppered bottles. The solution is more rapidly oxidized than the salt, but does not separate sulphur; likewise, not on the addition of hydrochloric acid (difference from thiosulphate). When heated to 100° C. (212° F.) the crystals lose all their water of crystallization (50 per cent.) without fusing or changing their shape, but at a red heat the salt fuses into an orange-red mixture of sodium sulphide and sulphate. The salt is nearly insoluble in alcohol, but dissolves readily in water. On heating the aqueous solution, saturated in the cold, anhydrous salt is deposited (Rammelsberg). The dry, anhydrous salt Na_2SO_3 (molecular weight 125.23) is nearly permanent in the air, and when immersed in a little water combines with it and forms a solid mass. The crystallized salt is soluble in 2 parts of water at 25° C. (77° F.) and in 1.4 parts of boiling water (U. S.). Diluted sulphuric or hydrochloric acid, added to the salt or its solution, liberates sulphur dioxide, which is recognized by its odor and by its turning black a strip of paper wet with mercurous nitrate solution. If held in a non-luminous flame an intense yellow color is imparted to the latter.

Tests.—If 1 Gm. of the salt be dissolved in 10 Cc. of diluted nitric acid and the solution heated sufficiently to expel the gases, the liquid should not become turbid (absence of thiosulphate). If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid and heated sufficiently to expel the sulphur dioxide, the remaining solution after restoring its original volume, should not be colored or rendered turbid by an equal volume of freshly prepared hydrogen sulphide test-solution, after standing well-stoppered at 35° C. (95° F.) for at least half an hour, either before or after the addition of ammonia water to slight alkalinity (absence of heavy metals). The salt is assayed by the method given under Sodii Bisulphis, page 1395, using 50 Cc. of tenth-normal iodine solution and 0.5 Gm. of the finely powdered salt. Not more than 11.66 Cc. of tenth-normal sodium thiosulphate should be required to titrate the excess of iodine, leaving

(50–11.66) 38.34 Cc. of iodine solution required by the sulphite, and corresponding to not less than 96 per cent. of pure salt. $Na_2SO_3.7H_2O + I_2 = Na_2SO_4 + 2HI + 6H_2O$. Each Cc. of iodine solution, containing 0.012589 Gm. of iodine, is equivalent to 0.01252 Gm. of crystallized sulphite, and 38.34 Cc. of iodine solution is equivalent to 0.47999 Gm. of pure sulphite, which is 96 per cent. of 0.5 Gm. taken for titration. The present titration method is the reverse of the former method, in which the iodine solution was added gradually *to* the solution of the salt, whereby error occurred by escape of sulphur dioxide. This is still the method in the Br., which demands that 1 Gm. of the salt shall require not less than 77.7 Cc. nor more than 81.7 Cc. of tenth-normal iodine solution. The theoretically required quantity is 79.88 Cc. of iodine solution. The lower limit, 77.7 Cc., correspouds to 97.27 per cent., while the higher limit can only be reached by the salt that has effloresced The U. S. P. of 1900 has dropped the tests for limit of sulphate and chloride, as these are innocuous and of no medicinal effect.

Action and Uses.—Sodium sulphite, in common with the other sulphites and sulphurous acid, possesses mild antiseptic and germicidal properties. In the acid secretion of the stomach it undergoes partial decomposition, which results in the liberation of sulphurous acid and the formation of sodium sulphate. It is absorbed and eliminated as sodium sulphate. In indigestion due to fermentation of the starchy and saccharine elements of food, producing pyrosis and vomiting of an acid, yeasty material, the administration of from 20 to 60 grains (1.30–4 Gm.) of sodium sulphite $\frac{1}{2}$ to 2 hours after meals will frequently give prompt relief. Applied in solution, 1 drachm to 1 ounce (4 Gm. : 30 Cc.) of water, it is curative to ulcers of the tonsils, aphthous stomatitis, mucous patches, and some parasitic skin diseases, as scabies and favus. The dose of sodium sulphite is from 20 to 60 grains (1.30–4 Gm.).

SODII THIOSULPHAS, *U. S.*—Sodium Thiosulphate.

Sodii Hyposulphis, U. S., 1890.—*Natrium thiosulfuricum*, P. G. ; *Natrium subsulfurosum* (*hyposulfurosum*). *Sodium hyposulphite*, E. ; *Hyposulphite de soude, Sulfite sulfuré de soude*, Fr. ; *Natriumthiosulfat*, G.

Formula, $Na_2S_2O_3 + 5H_2O$. Molecular weight, 246.46.

It should be kept in well-closed bottles, and should contain not less than 98 per cent. of the pure salt.—U. S.

The correct chemical name of this salt is sodium thiosulphate, as now recognized in the Pharmacopœia. Hyposulphites are entirely different salts, being derived from an acid having probably the composition $H_2S_2O_4$, while thiosulphates are derived from the acid $H_2S_2O_3$, which is sulphuric acid in which an atom of sulphur plays the part of an atom of oxygen, hence the name thiosulphuric acid. A salt of the true hyposulphurous acid is obtained by the action of zinc on sulphurous acid, zinc sulphite being formed and the liberated hydrogen reducing sulphurous to hyposulphurous acid, with the formation of water. The acid, known only in solution of its salts, which have a deep-yellow color, is a strong reducing agent. True sodium hyposulphite may be prepared by treating a solution of acid sodium sulphite (bisulphite) with metallic zinc, whereby sodium hyposulphite and sulphite, together with zinc sulphite, are formed. The salt is used by dyers and calico-printers for the reduction of indigo blue to indigo white.

Thiosulphuric acid, $H_2S_2O_3$, the acid present in the official salt, has never been obtained in a free state, but a series of stable salts (thiosulphates) has been prepared by boiling the respective sulphites in solution with sulphur ; thus, $Na_2SO_3 + S = Na_2S_2O_3$; they may also be obtained by adding iodine to a mixture of sulphite and sulphide, thus, $Na_2SO_3 + Na_2S + I_2 = Na_2S_2O_3 + 2NaI$, or by the action of sulphur on alkali hydroxide, when alkali pentasulphide is simultaneously formed. The fact that thiosulphates show a great tendency to form double salts, as well as their decomposition, when heated, into sulphates and sulphides, readily distinguishes them from true hyposulphites, which latter, when heated, break up into thiosulphates and water.

Preparation.—The salt is best prepared on the large scale. In the purification by dry lime of illuminating gas prepared from coal, the gas-lime contains calcium carbonate, thiosulphate, and pentasulphide, and is utilized for the manufacture of sodium thiosulphate by a process proposed by Graham. The gas-lime is exposed to the air so as to convert the sulphide into thiosulphate ; $2CaS_5 + 3O_2$ yields $2CaS_2O_3 + 2S_2$. It is then

treated with its weight of cold water, and the filtrate, which contains the calcium thiosulphate, is converted into the sodium salt by double decomposition with sodium carbonate, whereby insoluble calcium carbonate is produced and a solution of sodium thiosulphate obtained, which is concentrated and crystallized; $CaS_2O_3 + Na_2CO_3$ yields $CaCO_3 + Na_2S_2O_3$. The residue left in the preparation of soda, called soda waste, contains calcium sulphide, and is converted into sodium thiosulphate by a process nearly identical with the one just described. In decomposing calcium thiosulphate the sodium carbonate may be replaced by sodium sulphate, in which case calcium sulphate is precipitated.

Properties.—Sodium thiosulphate is in large, transparent, colorless, monoclinic prisms, which have the specific gravity 1.74, are neutral or faintly alkaline, are inodorous, and have a cooling, bitter, slightly alkaline, and sulphurous taste. It is permanent in the air, but over sulphuric acid it slowly parts with most of its water of crystallization, and in the atmosphere begins to effloresce at about 30° C. (91.4° F.). When slowly heated it parts with all its water of crystallization (36.3 per cent.) at 100° C. (U. S.), but if rapidly heated not below 215° C. (419° F.), and at about 225° C. (437° F.), it is decomposed, with the separation of sulphur (Pape); at a red heat it forms a black (after cooling brown-yellow) mass of sodium sulphate and sulphide, and some sulphur is also liberated. A non-luminous flame is colored intensely yellow by the salt. The crystallized salt dissolves at 25° C. (77° F.) in 0.35 part of water, readily forms supersaturated solutions, and at boiling heat the solution is rapidly decomposed; it is slowly soluble in oil of turpentine, the odor of the latter being modified (Edison, 1876), but it is insoluble in alcohol, and is precipitated by the latter from its concentrated solution as an oily liquid. The aqueous solution is gradually, or in the presence of free alkali more rapidly, decomposed into sulphur and sulphite. According to F. H. Alcock, a small quantity of carbon disulphide prevents this change. In the presence of zinc and free acid hydrogen sulphide is formed; on acidulating the solution of the salt, thiosulphuric acid is liberated, and at once decomposed into sulphurous acid and sulphur, which forms a white precipitate (difference from sulphites).

Sodium thiosulphate dissolves chloride, iodide, and other compounds of silver readily, and is employed for this purpose by photographers, and such a solution may be used for silvering copper and brass. Iodine is decolorized by a solution of sodium thiosulphate, sodium iodide and tetrathionate being formed, according to the equation $2Na_2S_2O_3.5H_2O + I_2 = 2NaI + Na_2S_4O_6 + 10H_2O$. This reaction affords a convenient method for the estimation of iodine, 125.9 parts of which are decolorized by 246.46 parts of the thiosulphate. A similar reaction takes place with chlorine, and makes the salt a useful and cheap *antichlor* for the removal of chlorine retained by fabrics and other substances which have been bleached by chlorine. Sodium thiosulphate is also a solvent for the insoluble salts of lead and other metals. It affords a white precipitate in a concentrated solution of barium chloride, which is soluble in much water (difference from sulphate).

Impurities.—If ferric chloride test-solution be dropped into the aqueous solution (1 in 20) of the salt, a dark-violet color will be produced, which disappears rapidly on agitation. If to 5 Cc. of the aqueous solution (1 in 10) 3 Cc. of nitric acid be added and the solution cautiously evaporated to dryness on a water-bath, and the residue, treated with distilled water, be filtered and washed, and the filtrate and washings evaporated to dryness, it should not respond to the modified Gutzeit's test for arsenic given under ARSENI TRIOXIDUM. The residue from 20 Cc. of the solution (1 in 20) treated in like manner, when dissolved in 20 Cc. of water and slightly acidulated with hydrochloric acid, and mixed with an equal volume of hydrogen sulphide solution, should not become colored or turbid on standing corked at 35° C. (95° F.) for half an hour, either before or after addition of ammonia water in slight excess (absence of heavy metals). The aqueous solution (1 in 20) should not be rendered turbid by the addition of ammonium oxalate test-solution (absence of calcium). The aqueous solution of the salt (1 in 20) should not be colored red by a drop of phenolphthalein test-solution (absence of caustic alkali or carbonate); nor should a drop of silver nitrate test-solution produce a brown or black precipitate in 5 Cc. of this solution (absence of sulphide). If 1 Gm. of sodium thiosulphate be dissolved in 20 Cc. of water, it should require not less than 39.75 Cc. of tenth-normal iodine solution to produce a distinct yellow tint (corresponding to at least 97.97 (98) per cent. of the pure salt).—U. S.

From the equation given above, explaining the reaction between sodium thiosulphate

and iodine, we learn that 492.92 parts of the former will decolorize 251.8 parts of the latter, and hence each Cc. of tenth-normal iodine solution (containing 0.01259 Gm. of iodine) so decolorized will represent 0.024646 Gm. of crystallized sodium thiosulphate, or 39.75 Cc. are equal to 0.9797 Gm., which is 97.97 (98) per cent. of 1 Gm.

Action and Uses.—The properties of sodium thiosulphate are similar to those of the sulphites. It is occasionally used for its antizymotic action to prevent fermentation due to the growth of sarcinæ and yeast fungi in the alimentary canal. Its chief use is in the treatment of parasitic skin diseases, especially pityriasis versicolor, to which it is applied in aqueous solution or ointment of the strength 1 drachm to the ounce (4 Gm. : 30 Cc.). Its administration for the relief of malarial hæmaturia is entirely empirical, but frequently successful. The dose of sodium thiosulphate is from 10 to 60 grains (0.60–4 Gm.).

SODIUM, *Br.*—Sodium.

Sodium, Fr. ; *Natrium*, G.

Symbol, Na. Atomic weight, 22.88. Valence, one in nearly all cases.

It was admitted in the Br. P. for preparing solution of sodium ethylate.

Sodium is a member of the family of alkali metals of which the characteristics have been mentioned under Cæsium, Lithium, and Potassium. It occurs in native rocks to nearly as great an extent as does the very similar metal potassium ; but while the potassium salts resulting from the decomposition of the rocks is taken up readily by plants, sodium finds its way, chiefly as chloride, through the medium of streams and rivers to the ocean, where it has accumulated for ages. The ashes of land plants are rich in potassium salts, while those of plants growing on shores and in the sea are richest in sodium salts. In the animal kingdom, sodium salts are abundant and in greater quantity than potassium salts. Sodium also occurs in great quantity as solid deposits in sodium chloride and sodium nitrate beds, and in Greenland as cryolite, a double fluoride of aluminum and sodium, $AlF_3.3NaF$.

Preparation.—Sodium, like potassium, was first isolated in 1807 by Sir H. Davy, of England, by electrolyzing molten sodium hydroxide. It was formerly made on a large scale by reduction of sodium carbonate with carbon in furnaces, but more recent and better methods are now used. As in the case of potassium, the method of electrolysis of molten sodium hydroxide or sodium chloride is used to a large extent. Castner introduced a successful method for the manufacture of sodium, which consists in the reduction of sodium hydroxide by heating it with an intimate mixture of finely divided iron and carbon. The mass is prepared by mixing the iron with molten pitch, allowing it to cool, breaking it into pieces, and heating to a comparatively high temperature without access of air. The reduction is said to take place at a temperature of 825°, instead of 1400°, as in the older method. The main reaction is represented by this equation: $6NaOH + FeC_2 = 2Na_2CO_3 + 6H + 2Na + Fe$.

Properties.—Sodium is like potassium in nearly all of its properties. It is silver gray, has a strong metallic lustre, and at ordinary temperatures may be cut like wax. It melts at 95.6° C. (204.08° F.), and at a red heat volatilizes. Its density is 0.974. In contact with air it is oxidized, and therefore requires to be kept under petroleum naphtha, or should be protected by being coated with a layer of paraffin, as proposed by Wagner (1863).

It decomposes water, forming sodium hydroxide and hydrogen, but the latter does not inflame as in the case of potassium. Sodium comes into the market in bars, while potassium is found mostly in spheres. The principal applications of sodium are: preparation of technical potassium cyanide (potassium and sodium cyanide mixture), used in gold extraction, also of sodium amalgam, which is used for the same purpose, in addition to its use in the laboratory as a reducing agent; preparation of sodium peroxide, for bleaching and oxidizing purposes; synthetic preparation of organic compounds, for example, acetoacetic ether and antipyrine.

The salts of sodium are colorless unless the acid is colored, have a neutral reaction except those with weak acids, and are not volatilized at a low red heat, and somewhat less readily than potassium salts at a higher temperature. They impart to flame an intense yellow color, which is not visible if examined through a blue glass. They are mostly readily soluble in water, and these solutions yield with hydrofluosilicic acid

gelatinous precipitates, and, when neutral or alkaline, afford with potassium metantimonate white crystalline precipitates. Similar precipitates are obtained with most other metallic salts, which must therefore be removed by the proper reagents, with the exception of those of potassium, before the test for sodium be applied.

Sodii Peroxidum, *Natrium superoxydatum s. peroxydatum. Sodium peroxide,* E.; *Natrium-superoxyd,* G. $NaO(Na_2O_2)$. This is the only oxide of sodium known with certainty. The oxide Na_2O, mentioned in nearly all text-books, cannot be made (Forcrand). The peroxide is made on a large scale by heating at 400° C. (752° F.) metallic sodium in shallow aluminum pans placed in long ovens through which air freed from moisture and carbon dioxide is passed. It is an almost white powder, more difficultly fusible than the hydroxide, very soluble in water with foaming and a great rise of temperature, the foaming being due to the decomposition of hydrogen peroxide which is first formed. Its chief use is as a bleaching agent, through the hydrogen peroxide generated when the powder is added to ice-cold dilute mineral acids, $Na_2O_2 + 2HCl = 2NaCl + H_2O_2$. It is also used in analytical chemistry as an oxidizer in place of nitrate and chlorate.

UNOFFICIAL SODIUM SALTS.

Sodii Caffeino-sulphonas.—*Sodium caffein-sulphonate,* E.; *Koffeinsulfosaures Natrium,* G. Symphorol-Na. Symphorol, $C_8H_9N_4O_2.SO_3Na$. Prepared by heating 100 parts of chlorocaffeine or an equivalent of bromocaffeine with 75 parts of anhydrous sodium sulphite and 1000 parts of water in an autoclave to 150° C. (302° F.) for 8 hours, the sodium caffeinsulphonate crystallizing out on cooling. A white crystalline powder having a bitter taste, and soluble in about 20 parts of water. This salt is recommended as a diuretic in dropsy and obesity. Its dose is from 15 to 60 grains (1–4 Gm.) a day.

Symphorol-L and Symphorol-Sr are the respective lithium and strontium salts.

Sodii Ethylas.—*Natrium æthylicum, sodium ethylate,* C_2H_5ONa. Obtained by action of sodium on absolute alcohol, hydrogen escaping. By evaporation, a pale reddish-yellow powder is obtained, having a caustic taste and soluble in water and alcohol. Used externally as a caustic of milder action than that of sodium hydroxide. Water decomposes it into alcohol and sodium hydroxide. Liquor sodii ethylatis is official in the Br. P., and is made by dissolving 1 Gm. of sodium in 20 Cc. of absolute alcohol. Sodium ethylate is applied in 10 per cent. aqueous solution in the treatment of lupus, psoriasis, and other skin diseases.

Sodii Ethylsulphas *s.* Sulphovinas.—*Sodium ethylsulphate* or *sulphovinate,* E.; *Sulfovinate de soude,* Fr. Cod.; *Aethylschwefelsaures Natrium,* G. $C_2H_5SO_4Na.H_2O$.—Sulphovinic acid is formed by mixing equal weights of alcohol and sulphuric acid, the mixture becomes hot and combination takes place thus, $C_2H_5OH + H_2SO_4 = C_2H_5HSO_4 + H_2O$. The mixture is treated with $BaCO_3$ (or $CaCO_3$), which forms soluble barium sulphovinate and precipitates any excess of free sulphuric acid. The mixture is filtered and the filtrate treated with sodium carbonate, which gives sodium sulphovinate and insoluble barium (or calcium) carbonate. The liquid is then evaporated at moderate heat and crystallized. Sodium sulphovinate crystallizes in shining, transparent, flat, six-sided tables, which effloresce on exposure to dry air. When obtained by spontaneous evaporation, the salt is granular and forms white opaque crystalline aggregations; and if crystallized from an alcoholic solution it contains alcohol in the place of water of crystallization. Heated to about 80° C. (176° F.), the crystals melt and rapidly part with their water, amounting to 10.8 per cent.; and if the heat is increased to 100° C. (212° F.) or a little above this point, the salt is decomposed, with the formation of sodium sulphate, charcoal, heavy oil of wine, and of sulphurous acid, ethylene, and other gases. The aqueous solution of the salt, when heated to boiling, is decomposed, in the same manner as all sulphovinates, into alcohol, which distils off, and acid sodium sulphate: this decomposition takes place more rapidly in concentrated than in diluted solutions. Crystallized sodium sulphovinate dissolves at ordinary temperatures in a little more than half its weight of water, and is soluble in glycerin and ordinary alcohol, sparingly soluble in absolute alcohol, and insoluble in ether. Its solution is neutral to test-paper and has a slightly bitter, afterward sweetish, taste. The aqueous solution of the salt should yield only a slight precipitate with barium chloride (sulphate), should not be colored by hydrogen sulphide (absence of lead), and should not be rendered turbid by sodium carbonate (absence of lead, barium, and calcium).

Sodii Fluoridum.—*Sodium fluoride,* E.; *Fluorwasserstoffsaures Natrium,* G.; *Fluorol,* NaF.—This is obtained by neutralizing hydrofluoric acid with sodium hydroxide. It is a white crystalline powder, soluble in 25 parts of water, and has a saline taste. It attacks glass, and should be kept in rubber bottles. Given in epilepsy, malaria, skin diseases, tuberculosis, in doses of $\frac{1}{12}$ to $\frac{1}{6}$ grain (0.005–.01 Gm.). Externally as antiseptic in aqueous solution, 0.5 to 10 to 1000. Technically to prevent lactic and butyric fermentation in the manufacture of alcohol, 10 to 15 Gm. NaF to 1000 liters of mash.

Sodii Formas.—*Sodium formate. Ameisensaures Natrium*, G. $HCO_2Na.H_2O$.—It is prepared by neutralizing formic acid with pure sodium carbonate or bicarbonate. It crystallizes in colorless rhombic plates or prisms, which are inodorous, have a saline bitter taste, melt in their water of crystallization, are deliquescent in moist air, and dissolve freely in water.

Sodii Glycerophosphas.—*Sodium glycerophosphate.* $C_3H_7O_3PO_3Na_2.H_2O$.—Obtained by neutralizing glycerophosphoric acid (which see). It occurs in the market as a 50 per cent. solution of a clear, light-yellow color. Used in convalescence, nervous asthma, and when the system needs phosphorus, in dose of 3 to 4 grains (0.2–0.25 Gm.) a day subcutaneously. As a substitute for jaborandi, when the latter is objectionable, injections on each side of the lumbar region are given in dose of 5 to 8 grains (0.3–0.5 Gm.) a day.

Sodii Methylsulphas.—*Sodium methylsulphate.* $CH_3SO_4Na.H_2O$. Prepared precisely like the ethylsulphate, except that methylic alcohol is substituted for ordinary alcohol. It resembles the sulphovinate in properties, and has been recommended for similar purposes.

Sodii Nitroferricyanidum.—*Sodium nitroferricyanide* or *nitroprusside.* $Na_2Fe(CN)_5NO.2H_2O$.—This is a salt of nitroferrocyanic acid, which is obtained by the action of nitric acid on potassium ferrocyanide. Potassium nitrate is crystallized out by concentrating and cooling the solution, which is then neutralized by sodium carbonate, and the sodium salt crystallized. Addition of alcohol increases the separation of potassium nitrate. The salt forms large ruby-red crystals, soluble in 2.5 parts of water and in alcohol. The aqueous solution decomposes on standing. It serves as a delicate test for soluble sulphides (but not free H_2S), giving a purple color which quickly passes into violet. It is also used as a test for acetone (Legal's test).

Sodii Oleas.—*Sodium oleate, Eunatrol.*—This preparation is supposed to be pure sodium oleate, but, according to B. Fischer, consists of 70 per cent. of the oleate and 30 per cent. of free oleic acid. It is made by saponifying 100 parts of oleic acid with 10 parts of pure dry caustic soda in alcoholic solution and evaporating to dryness. It is a white, soft, soapy mass, weakly alkaline to litmus, and forms a murky solution. It is used in pill form, in dose of 15 grains (1 Gm.), twice daily as a cholagogue.

Sodii Silicas.—*Sodium silicate.* Na_2SiO_3.—This is made by fusing at high heat 100 parts of anhydrous sodium carbonate and 56.6 parts of powdered quartz (SiO_2). By dissolving the mass in water and concentrating, crystals of the salt may be obtained, which, when redissolved in water, give a solution of so-called water glass, which has been given internally for gout, in dose of 5 to 15 grains (0.3–1 Gm.) of a $33\frac{1}{3}$ per cent. solution, diluted with much water, 3 or 4 times daily. Externally it is used to impregnate paper, linen, gauze, etc., for bandages; when used for this purpose it should be free from excess of alkali, which would corrode the skin. It is also used technically for making objects fireproof, manufacturing artificial stone, cements, etc. Its solution, official in the U. S. P., 1890, is used in making splints for fractures, dislocations, etc.

Sodii Sulphoricinas.—*Sodium sulphoricinate, Solvin, Polysolve.*—A brownish, thick liquid, soluble in alcohol and water, and used as a solvent for phosphorus, iodine, iodoform, naphthalene, phenol, resorcin, etc., for antiseptic purposes. Concentrated sulphuric acid, acting on fats or fatty acids, gives sulphoricinic acid, from which the sodium salt is obtained by neutralization.

Sodii Valerianas.—*Sodium valerianate, Valérianate de soude*, Fr.; *Baldriansaures Natrium, Natriumvalerianat*, G. $C_5H_9O_2Na$.—Obtained by neutralization of valerianic acid (which see) with sodium hydroxide and crystallizing. It forms a white crystalline mass, which is rather unctuous to the touch, and has a neutral or slight alkaline reaction, a weak odor of valerian when perfectly dry, and a sweet and valerian-like taste. It melts at 140° C. (284° F.) without decomposition to a colorless liquid, and on cooling congeals crystalline; at a higher heat it gives off pungent acid vapors and inflammable gas, and leaves 42.75 per cent. of sodium carbonate. The salt is freely soluble in alcohol and water, and on exposure to the atmosphere liquefies from the absorption of water. On the addition of diluted sulphuric acid a strong odor of valerianic acid is given off. The solution of sodium valerianate in water should not be colored by hydrogen sulphide and ammonium sulphide (absence of metals), and should yield no precipitate with barium chloride (absence of sulphate). Sodium valerianate may be used interchangeably with ammonium valerianate. Its dose is from 5 to 20 grains (0.30–1.30 Gm.).

Phenol Sodium Sulphoricinate is the only preparation of importance, and occurs in the market in two forms, containing respectively 25 and 30 per cent. of phenol. It is used as a local caustic in nasal and laryngeal papilloma and ulcers and chronic inflammations.

SOLANACEÆ.—The Potato Family.

The potato family, most largely represented in tropical and almost wanting in cool-temperate regions, comprises some 75 genera and probably not far from 2000 species, though only about 1600 are admitted by Wettstein.

FOOD-PLANTS.

As represented by the potato, tomato, egg-plant, pepper, physalis, and less well-known tropical fruits, it is one of the great food-families of plants.

The *tomato* (*Lycopersicum esculentum* L.), at first regarded as poisonous, later suspected of causing cancer and, not so very long ago, condemned by the British army as unwholesome, has now proved itself one of the most wholesome of juicy vegetables. Abundant, cheap, and readily preserved, it has come to be of the greatest value as an addition to the winter diet, and to the bill of fare of soldiers, sailors, and others unable to secure fresh food. It has even been credited with medicinal properties, an idea which, in the absence of experimental evidence, can be regarded as probably correct. Davis reported obtaining from the fruit, upon distillation with water, an oil identical with volatile oil of mustard. Briosi and Gigli reported from 0.4 to 0.65 per cent. of citric acid and traces of tartaric acid, as well as of an alkaloid, in the juice. Levulose was present, and the coloring-matter was reported as showing resemblances to that of saffron.

Physalis L.—A number of the 45 species of this genus produce delicious edible fruits, some varieties of which are important articles of trade in the West Indies, Mexico, and other Andean countries, under the name *Tomatillo*. *Alkekengi* (*Fructus* or *Baccæ Alkekengi* or *halicacabi*.—*Strawberry-tomato*, *Winter-cherry*, *Ground-cherry*, *Bladder-fruit*, E.; *Indenkirsche*, *Blasenkirschen*, *Schluta*, G.; *Coqueret*, Fr.; *Alkekenges*, Sp.) is the fruit of *P. Alkekengi* L. (*Alkekengi officinarum* Moench.), a European species, extensively cultivated. Other species, especially *P. Peruviana* L. (*Alkekengi pubescens* Moench.), and the Mexican *P. ixocarpa* Bert. (*P. æquata* Jacq.), bear similar names. Alkekengi is borne upon a low-spreading, softly-hairy herb. The fruit is spherical, of the size of a cherry, scarlet red, shining, and remains enclosed in the inflated orange-colored permanent calyx. It is 2-celled, and contains numerous white flattish ovate seeds attached to a central placenta. In the fresh state the fruit is very juicy and has a sweet and acidulous taste; it shrivels considerably on drying. The fruit has a composition similar to that of the tomato, though more sugary. The herbage contains an amorphous bitter principle *physalin*, $C_{14}H_{16}O_5$, which is obtained as a whitish powder on agitating the cold aqueous infusion with chloroform, and is soluble in chloroform and alcohol, but sparingly so in ether, cold water, and diluted acids.

MEDICINAL PLANTS.

Although several of the plants referred to above have more or less medicinal repute, they are to be regarded rather as food-plants than distinctly medicinal, as are those which follow. The most important, as well as the most common, medicinal properties of this family reside in the so-called mydriatic or solanaceous alkaloids which have been discussed separately and in connection with Belladonna, *Duboisia*, Dulcamara, and other solanums, Hyoscyamus, Scopola, and Stramonium. Very different properties, exceptions in the family, are represented in *Nicotiana*, *Fabiana*, and Capsicum. The family contains many secondary drugs possessing mydriatic, and a few possessing special properties, the most important of which are considered below:

Mandragora, the *European Mandrake*, *Mandrake Apple* or *Devil's Apple* (*Alraunwurzel*, *Schlafapfel*, G.), is the plant, more especially its root, *M. officinarum* L. (*M. officinalis* Mill.; *M. vernalis* Bertol.; *Atropa Mandragora* L.), and is a most ancient narcotic drug, the mandrake of the Bible. It was probably due to the peculiar form of the root, which often bears a fancied resemblance to that of the human body, that aphrodisiac properties were attributed to it. Its real properties, which are pronounced, are due to its mydriatic alkaloids, originally called *mandragorine*, now known to be practically identical with those of stramonium and hyoscyamus. Wentzel isolated a little alpha-methoxy-methylpiperidine, myristic acid, phytosterin, chrysatropic acid ($C_{10}H_8O_4$), and glucose.

There are 3 or 4 species in this genus, and the others probably share in the properties of that above described.

Lycium L. is a genus of some 70 species, several of which have been used for their mydriatic and diuretic properties, notwithstanding that the fruits of some are edible, and the young herbage of others cooked as a table vegetable. *L. vulgare* (Ait. f.) Duval (*L. Barbarum vulgare* Ait. f.), the *Matrimony Vine*, *Bastard jasmine* or *Box Thorn*, native of Europe and cultivated as an ornamental shrub, has been used as a mydriatic, though it is said that its alkaloid is only *betaine*, and this artificially derived by chemical manipulation. The facts may be considered as not yet established.

Manaca, Manacan, Mercurio Vegetal, Camganiba, or *Geratacaca,* is the root of *Brunfelsia Hopeana* Benth. (*Franciscea uniflora* Pohl), a large shrub of the Amazon valley. The drug is a crooked, branching, hard and tough woody root, the outer surface purplish red, either smooth or somewhat fissured and scaling, the wood yellowish white. The bark has a not strong narcotic and nauseous taste. Its most important constituent appears to be resin, though a crystalline powder of alkaloidal character has been imperfectly described under the name *manacine.*

The fruit of *Nicandra physaloides* Gaertn., of Peru, sparingly naturalized elsewhere, is used as a diuretic. The leaves of *Cestrum Parqui* L'Her., the *Parqui* or *Palqui* of Chili, are highly narcotic, poisonous, and both they and the wood are employed medicinally, as are a dozen others of the 159 species of this genus, and several of the similar plants *Sessea* and *Vestia.* In all, some 250 members of the *Solanaceæ* are recorded as being used medicinally.

Lachnanthes.—Although this drug, also called *Red-* or *Paint-root, Spirit-weed* or *Wool-flower,* is not at all related to the *Solanaceæ,* it is mentioned here because the effects of overdoses are said to resemble those of mild poisoning by belladonna and other solanaceous drugs. It is the entire plant, but especially the rhizome and roots, of *Gyrotheca capitata* (Walt.) Morong (*Anonymos c.* Walt.; *Lachnanthes tinctoria* Ell.; *Gyrotheca t.* Salisb.), growing in damp soil in the pine barren regions, along the Atlantic coast and in Cuba. The plant is a perennial herb about 4 to 6 Dm. (1½ to 2 Ft.) high, the upper portions white-woolly. The rhizome is about an inch in length and of nearly equal thickness and bears a large number of long, coarse, somewhat waxy, deep-red roots. The leaves are mostly borne in basal rosette and somewhat succulent, falcate, 5 to 15 Mm. (⅕ to ⅗ In.) wide, and reduced to bracts upward upon the stem. The flowers are in a close, woolly cyme, the ovary inferior, the perianth six-parted, the sepals narrower than the petals, the stamens 3, alternating with the petals, on long filaments; the style is solitary, filiform, and declined, its stigma slightly 2-lobed; the fruit a 3-celled, many-seeded, rounded, and truncate capsule. The constituents of the plant are entirely unknown, but are quite active, producing a peculiar form of cerebral stimulation or narcosis. In the country where it grows, there is a legend that it is fatally poisonous to white pigs, but not injurious to black ones. Aside from its narcotic use among the Indians, it has been used for dyeing purposes. The drug is used by the Eclectics and Homœopaths in the usual unscientific and indefinite manner for various nervous disorders.

SPARTEINÆ SULPHAS, *U. S.*—Sparteine Sulphate.

Sulfate de spartéine, Fr. Cod.; *Sparteinum sulfuricum.*—*Sparteinsulfat, Schwefelsaures Spartein,* G.

Formula, $C_{15}H_{26}N_2.H_2SO_4 + 5H_2O$. Molecular weight, 419.26.

The sulphate of an alkaloid obtained from Scoparius. It should be kept in well-stoppered amber-colored vials.—U. S.

Preparation.—Sparteine sulphate may be prepared by dissolving the alkaloid sparteine (see p. 1371), preferably recently distilled, 10 parts, in 40 parts of diluted (10 per cent.) sulphuric acid and allowing the solution to crystallize in a warm place.

Properties and Tests.—Sparteine sulphate occurs as colorless, rhombohedral crystals, or as a crystalline powder, which are odorless and have a slightly saline and somewhat bitter taste. It crystallizes with varying amounts of water of crystallization, but when recrystallized from a solution in diluted alcohol it contains 5 molecules of water. It is soluble in 1.1 parts of water, and in 2.4 parts of alcohol at 25° C. (77° F.); insoluble in ether and chloroform. When heated to 110° C. (230° F.), the salt loses all of its water of crystallization (21.3 per cent.), and when anhydrous, melts at 136° C. (276.8° F.). It is hygroscopic, and its aqueous solution has an acid reaction upon blue litmus-paper. If 25 Cc. of ether be added to about 0.1 Gm. of sparteine sulphate in a test-tube, followed by a few drops of diluted ammonia-water, avoiding an excess, and if an ethereal solution of iodine (1 in 50) be afterwards added until the liquid, when shaken, turns from an orange to a dark reddish-brown color, the bottom and sides of the test-tube will, after a short time, be coated with minute, dark greenish-brown crystals. Barium chloride test-solution, in an aqueous solution of sparteine sulphate, produces a white precipitate insoluble in hydrochloric acid. If a solution of potassium ferrocyanide (1 in 20) be added to a solution of the salt a yellow precipitate is produced. Sulphuric acid, when added to sparteine sulphate, should not become colored (absence of sugar and other readily carbonizable organic impurities). On shaking 0.05 Gm. of sparteine sulphate in a test-tube, with 5 Cc. of potassium hydroxide test-solution, the liquid will at first be turbid, and small drops of sparteine will gradually

collect on the surface. If a strip of moistened red litmus-paper be suspended in the mouth of the test-tube, and a gentle heat then applied, the test-paper will gradually acquire a blue color, but no odor of ammonia should be perceptible (absence of ammonium salts).—U. S.

Action and Uses.—The properties and uses of sparteine sulphate are considered under SCOPARIUS. Its dose varies, is from ½ to 2 grains (0.008–0.12 Gm.).

SPECIES AROMATICÆ, *P. G.*—Aromatic Herbs.

Espèces aromatiques, Fr.; *Gewürzhafte Kräuter*, G.

Preparation.—Peppermint (leaves), wild thyme (herb), thyme (herb), lavender (flowers), of each 2 parts; cloves, 1 part. Having cut these drugs into fine particles, add 1 part of coarsely-powdered cubebs and mix the whole thoroughly.—P. G.

SPECIES DIURETICÆ, *P. G.*—Diuretic Tea.

Espèces diuretiques, Fr.; *Harntreibender Thee*, G.

Preparation.—Lovage (root), rest-harrow (root), licorice (root), of each 1 part. Having cut these drugs into coarse particles, add 1 part of juniper berries, previously crushed, and mix thoroughly.—P. G.

SPECIES EMOLLIENTES, *P. G.*—Emollient Herb-mixture.

Espèces emollientes, Fr.; *Erweichende Kräuter*, G.

Preparation.—Marshmallow (leaves), mallow (leaves), melilot (herb), German chamomile (flowers), flaxseed, of each 1 part. Having ground the drugs to a coarse powder, they are thoroughly mixed.—P. G.

SPECIES LAXANTES, *P. G.*—Purgative Tea.

Espèces purgatives, Fr.; *Abführender Thee*, G.

Preparation.—Senna, in very coarse powder, 160 parts; elder flowers, 100 parts; fennel, crushed, 50 parts; anise, crushed, 50 parts; potassium tartrate, 25 parts; tartaric acid, 15 parts. Dissolve the potassium tartrate in 50 parts of water and moisten the fennel and anise uniformly with the solution; after 30 minutes dissolve the tartaric acid in 15 parts of water and add this solution to the previous mixture and dry the whole with the aid of gentle heat. Finally add the senna and elder flowers and mix thoroughly.—P. G.

SPECIES LIGNORUM, *P. G.*—Wood Tea.

Species ad decoctum lignorum.—Espèces sudorifiques, Fr.; *Holzthee*, G.

Preparation.—Guaiac (wood), 5 parts; rest-harrow (root), 3 parts; licorice (root), 1 part; sassafras (bark), 1 part. Having coarsely cut or crushed the drugs, they are thoroughly mixed.—P. G.

SPECIES PECTORALES, *P. G.*—Pectoral Tea.

Espèces pectorales, Fr.; *Brustthee*, G.

Preparation.—Marshmallow (root), 8 parts; licorice (root), 3 parts; orris (root), 1 part; colt's foot (leaves), 4 parts; mullein (flowers), 2 parts; anise, crushed, 2 parts. Reduce the marshmallow, licorice, orris, colt's foot, and mullein to a very coarse powder and mix with the anise.—P. G.

SPIGELIA, *U. S.*—Spigelia.

Pinkroot, Maryland, Carolina or Indian Pink, Worm-grass or *Worm-weed, Starbloom*, E.; *Marylandische Spigelia*, G.; *Spigélie du Maryland, Spigélie anthelmintique*, Fr.; *Cravo do Carolina*, Port.

The dried rhizome and roots of *Spigelia Marilandica* L. (Fam. *Loganiaceæ*).

Spigelia is official in several other pharmacopœias, most of which name *S. Anthelmia* L. ("*S. anthelmintica*," Ph. Belg.), and specify the flowering plant.

Origin.—The Maryland pink is a simple-stemmed, nearly smooth, perennial herb, a foot or two high, of the habit shown in the accompanying illustration. The flowers are scarlet red externally reddish, yellow within. It occurs sparingly north of Maryland and southern Ohio, extending as far as Wisconsin and New Jersey. South of these points it was formerly very abundant, but has been largely destroyed by collection. Owing to a similarity of name, the rhizome and roots of *Ruellia* (Fam. *Acanthaceæ*) have been very extensively mixed with and sold for it.

Description.—The rhizome of oblique and sharply flexuous growth, somewhat branched, mostly 2.5 to 5 Cm. (1–2 In.) long and 2 to 4 Mm. ($\frac{1}{12}$–$\frac{1}{6}$ In.) thick, knotty from the approximate stem-bases of the upper surface, which bear cup-shaped scars, dark brown or blackish, thickly clothed underneath and at the sides with long, rather coarse, finely branched, lighter-brown roots, which are usually broken shortly, not leaving a long, bare, woody central portion; brittle, showing a whitish wood and a dark or decayed pith; somewhat aromatic; taste sweetish, bitter, and somewhat pungent.

The larger, lighter colored rhizome of *Ruellia*, Sp., with fewer coarse roots, from which the bark readily separates, is frequently substituted or admixed.

Fig. 405. Fig. 406.

Spigelia: flowering-top (½ Nat.); rhizome with roots (enlarged ⅕).

The powder is dark brown and is characterized by the presence of numerous rounded and oblong stone-cells, the latter blunt to nearly square at the ends, by cells containing single quadrangular crystals of calcium oxalate, occasional acicular raphides, and rather few starch-grains.

Adulterants and Substitutes.—Spigelia is so far subject to sophistication that an absolutely genuine and pure article is probably the exception. Besides the ruellia referred to above, the rhizome and roots of *Phlox glaberrima* L. are said to be used in some localities. It is somewhat darker and less ridged than ruellia and more closely resembles spigelia. The drug, and still more the adulterant, are very apt to retain an undue amount of earthy matter.

Constituents.—The active constituent of spigelia appears to be the volatile, crystallizable alkaloid *spigeline*, obtained by distillation with milk of lime. The constitution of this alkaloid has not been investigated. It is soluble in both alcohol and water, yields with iodine a brownish-red precipitate, with metatungstic acid a white flocculent precipitate, and with Mayer's reagent a white crystalline precipitate, soluble in alcohol and ether, and differing from the precipitates of other alkaloids produced in this way in being soluble in acids. There is also present in spigelia a small amount of volatile oil, fat,

wax, tannin, and a tasteless resin. Whether there is a specific bitter principle in addition to spigeline is uncertain.

Pharmaceutical Preparation.—Fluidextract of Spigelia, U. S. P.

Action and Uses.—The anthelmintic properties of spigelia have been known to the medical profession of America since 1754, when its employment was recommended by three South Carolina physicians, Drs. Lining, Garden, and Chalmers, who learned of its virtues from the aborigines. The symptoms produced by toxic doses of the drug upon the human organism were described by Dr. Chalmers, and correspond closely to those observed by Dr. H. A. Hare in his experiments with spigelia upon dogs. They consist in a hot, dry skin and fauces, an accelerated circulation, dilated pupils, internal strabismus, exophthalmus, general motor paralysis, drowsiness deepening into coma, slowed respiration, and death from paralysis of the respiratory centre. In the proper dose, spigelia is a safe and efficient anthelmintic, particularly if it be followed by a rapidly acting purge, as magnesium sulphate. The dose of spigelia is from 10 to 20 grains (0.60–1.30 Gm.) to a child under 5 years of age, and from ½ to 2 drachms (2–8 Gm.) to an adult. It is commonly given in infusion in combination with purgative and aromatic drugs, as senna, manna, and fennel. The fluidextract of spigelia and senna formerly official is a convenient and efficient preparation, given in the dose of ½ drachm (2 Cc.) to a child, and as much as ½ ounce (16 Cc.) to an adult. The dose of the fluidextract is the same as of the drug in substance.

Other Spigelias.—The genus *Spigelia* L. comprises some 30 species, all American, mostly tropical, and several of them are employed like the official. This is especially true of *S. Anthelmia* L., native of the West Indies and northern South America, where it is very abundant. It has a similar habit to Pinkroot, but the lance-ovate acuminate leaves are mostly in whorls of 4, the light-reddish flowers are only half an inch long, the rhizome is short, blackish externally, whitish internally, and bears numerous long, thin roots. The drug has a stronger narcotic and bitter taste than the official. It has been introduced to use in Europe, and the Belgian Pharmacopœia specifically states that it is more active than our official species.

SPIRITUS.—Spirits.

Alcoolats, Fr.; *Geiste*, G.

Spirits were formerly prepared almost exclusively by distilling odorous substances with alcohol; at present, however, both the United States and British Pharmacopœias direct most of them to be prepared simply by dissolving the volatile oils and other volatile compounds in alcohol. Whenever volatile oils are used in the preparation of spirits, only the very best should be selected, as the value of the finished product depends entirely upon the quality of the oil; particular attention should be paid to those oils likely to have acquired a terebinthinate odor, such as the oils of juniper, lemon, nutmeg, and orange peel. Since odorous principles volatilize only sparingly with the vapors of alcohol, but more freely with the vapors of water, distilled spirits are made with alcohol sufficiently diluted with water, so that a portion of the latter remains in the still on the completion of the process. The German Pharmacopœia usually directs alcohol and water in the proportion of 3 parts of the former to 3 or 5 parts of the latter; after due maceration with the bruised drug 4 parts by weight of distillate are recovered. The alcoolats of the French Codex are generally made with 60 or 80 per cent. alcohol, the fresh drugs being used whenever practicable. In all cases the alcohol employed should be free from fusel oil, and the drugs should be well bruised and macerated with the alcohol for one or several days before distillation is commenced. In distilling spirits the same precaution should be adopted as in the distillation of medicated waters, with this addition, that ample provision be made for the complete condensation of the vapors. Heat is best applied by means of steam or on a small scale by means of a salt-water bath.

SPIRITUS ÆTHERIS, *U. S., Br.*—Spirit of Ether.

Spiritus œthereus, P. G.; *Liquor anodynus mineralis Hoffmanni, Æther sulfuricus alcoolisatus, Éther officinal alcoolisé*, Fr. Cod.—*Éther sulfurique alcoolisé, Liqueur d'Hoffmann*, Fr.; *Hoffmannstropfen*, G.

Preparation.—Ether, 325 Cc.; alcohol, 675 Cc.; to make 1000 Cc. Mix them.—U. S. Ether, 10 fluidounces; alcohol (90 per cent.), 20 fluidounces.—Br. Ether and alcohol, of each equal weight.—Fr. Cod. Ether, 1 part; alcohol, 3 parts.—P. G.

This preparation is used in Europe as a simplified form of *Hoffmann's anodyne* and for similar purposes.

Uses.—Spirit of ether may be used in all cases for which ether is prescribed internally. Its dose is from 1 to 3 drachms (4–12 Cc.).

SPIRITUS ÆTHERIS COMPOSITUS, *U. S., Br.*—Compound Spirit of Ether.

Hoffmann's anodyne, E.; *Liquor nervine de Bang*, Fr.; *Zusammengesetzter Ätherweingeist*, G.

Preparation.—Ether, 325 Cc.; alcohol, 650 Cc.; ethereal oil, 25 Cc.; to make 1000 Cc. Mix them.—U. S.

To prepare 10 fluidounces of compound spirit of ether, mix 3¼ fluidounces of ether, 2 fluidrachms of ethereal oil, and 6½ fluidounces of alcohol.

Take of ether 5½ fluidounces; alcohol (90 per cent.), 78 fluidounces; sulphuric acid, 36 fluidounces; distilled water, 1½ fluidounces; sodium bicarbonate, a sufficient quantity. Gradually mix the sulphuric acid with 40 fluidounces of the alcohol; let the mixture stand for 24 hours. Then distil slowly until the thermometer, the bulb of which is within the liquid, indicates a temperature of 171.6° C. (341° F.). Pour the distillate into a separator, and, after separation is complete, remove the lower layer. Add the distilled water to the upper layer, and also, gradually, sodium bicarbonate, until after agitation the liquid is nearly neutral to litmus-paper. Separate the ethereal liquid, and add to it the ether and 38 fluidounces of the alcohol. Filter.—Br.

Properties.—Compound spirit of ether is a colorless, inflammable liquid, entirely volatilized by heat, but when ignited on glass or porcelain it leaves an almost invisible residue having an acid taste and reddening blue litmus-paper. The spirit is neutral to test-paper, or has only a very slight acid reaction. It has an aromatic ethereal odor and a pungent, slightly sweetish taste. When mixed with water a whitish turbidity is produced from the separation of oil of wine, and a slight opalescence is still observed if 40 drops of the spirit are mixed with a pint of water. If adulterated with a fixed oil, this will separate from the water as a thin film, which, when absorbed by bibulous paper, produces a permanent greasy stain, not disappearing by heat. On evaporating some of the spirit with an excess of aqueous solution of barium chloride, a white precipitate of barium sulphate is produced.

While an assay method for determination of the ethyl sulphate content of a compound spirit of ether would be desirable, the U. S. P. names neither properties nor tests for the preparation. The Brit. Pharm. makes the following statements: "A colorless mobile liquid, with characteristic ethereal odor and taste. Specific gravity, 0.808 to 0.812. It gives an opalescent solution when mixed with twice its volume of water. 2 or 3 Cc. evaporated spontaneously on a watch-glass should not yield a residue having an unpleasant odor (absence of empyreumatic impurities)."

The preparations of the two pharmacopœias resemble each other in composition, that of the U. S. P. being more definite and containing a larger proportion of ether. Unfortunately much of the commercial article sold under the name of Hoffmann's Anodyne fails to correspond to the official spirit, and care is necessary in the purchase and use of the same. It is rarely made by the official formula, but is obtained in the manufacture and rectification of ether as a by-product, the last fraction of the distillate, consisting of a mixture of alcohol and ether containing small proportions of light and heavy oil of wine being collected. This is variously diluted with alcohol, ether, and water, so as to bring the product up to an arbitrary standard fixed by the manufacturer and somewhat resembling the official spirit. These inferior products can be readily distinguished from the official by a markedly decreased turbidity upon admixture with water, and also in producing only a slight precipitate with barium chloride solution. They should never be dispensed when compound spirit of ether is prescribed.

Action and Uses.—Compound spirit of ether is stimulant, antispasmodic, and anodyne. From experiments with heavy oil of wine, Dr. H. A. Hare concludes that it does not possess the sedative action ascribed to it, and that the calmative effect of Hoffman's anodyne depends largely upon the ether. It is an excellent carminative, acting promptly and thoroughly. Given by rectal injection in the dose of ½ ounce (16 Cc.), diluted with water or milk of asafetida, it is the best remedy to relieve tympanites occur-

ring in typhoid fever and peritonitis. For the acute cardiac palpitation, nausea, and depression due to excessive use of tobacco, no other drug is quite so efficacious. It gives prompt relief in many cases of hiccough. Attacks of angina pectoris, induced by gaseous distention of the stomach, soon yield to full doses of Hoffman's anodyne. It may be employed to allay the restlessness and insomnia of nervous irritation and hysteria. The dose of compound spirit of ether is from ½ to 2 drachms (2–8 Cc.). It should always be diluted with cold water before it is taken.

SPIRITUS ÆTHERIS NITROSI, *U. S., Br., P. G.*—Spirit of Nitrous Ether.

Spiritus nitri dulcis; Spiritus nitrico-æthereus.—Sweet spirit of nitre, E.; *Éther azoteux alcoolisé, Liqueur anodine nitreuse,* Fr.; *Versüsster Salpetergeist, Salpeteræther-weingeist,* G.

An alcoholic solution of ethyl nitrite ($NO.OC_2H_5$), yielding, when freshly prepared and tested by the process given below, not less than 4 per cent. of ethyl nitrite.—U. S.

An alcoholic solution containing ethyl nitrite, aldehyde, and other substances.—Br.

Preparation.—Sodium nitrite, 100 Gm.; sulphuric acid, 40 Cc.; monohydrated sodium carbonate, 0.6 Gm.; potassium carbonate, completely deprived of water by drying, 3 Gm.; alcohol, water, of each a sufficient quantity. Mix the sulphuric acid with 120 Cc. of water, cool the liquid, add 85 Cc. of alcohol previously diluted with an equal volume of water, and introduce the solution into a 1000 Cc. flask, surrounded by a mixture of ice and water. Dissolve the sodium nitrite in 280 Cc. of water, filter, and, having poured the filtrate into a separatory funnel, allow the liquid to slowly drop into the flask containing the acid mixture. When all has been added and the reaction is complete, allow any crystals which may have formed to settle at the bottom of the flask, and decant the cold mixture of ethyl nitrite and aqueous solution quickly to the previously cleaned separatory funnel, and draw off and discard the aqueous liquid. Wash the separated ethyl nitrite, first, with 20 Cc. of ice-cold water, and then remove any traces of acid by washing it with 15 Cc. of ice-cold water, in which the monohydrated sodium carbonate has previously been dissolved. Carefully separate the ethyl nitrite from the aqueous liquid, and agitate it in a well-stopped vial with the potassium carbonate to remove traces of water. Then cool the liquid, decant, and pour the ethyl nitrite immediately into a tared bottle containing 500 Gm. of alcohol. Ascertain the weight of the ethyl nitrite poured into the alcohol by noting the increase in weight of the tared bottle and contents, and then add enough alcohol to make the mixture weigh 22 times the weight of the ethyl nitrite added. Lastly, transfer the product to small, well-stoppered, dark amber-colored vials, and keep these in a cool place, remote from lights or fire. —U. S.

Take of nitric acid 3 fluidounces; sulphuric acid, 2 fluidounces; copper, 2 ounces; alcohol (90 per cent.), a sufficient quantity. To 1 pint of the alcohol add gradually the sulphuric acid, stirring them together; then add in the same way 2½ fluidounces of the nitric acid. Put the mixture into a retort or other suitable apparatus into which the copper has been introduced and to which a thermometer is fitted. Attach now an efficient condenser and receiver, the latter containing 20 fluidounces of the alcohol, and applying a gentle heat, let the alcohol distil at a temperature commencing at 170° F., but not exceeding 180° F., until the volume of liquid in the receiver has been increased to 32 fluidounces, the receiver and condenser being kept cool with ice-cold water; then withdraw the heat, and having allowed the contents of the retort to cool, introduce the remaining ½ ounce of nitric acid, and resume the distillation as before until the liquid in the receiver has been increased to 34 fluidounces. Mix this liquid with 1 pint of the alcohol, or as much as will make the product contain 2½ per cent. of ethyl nitrite when tested as described below. Preserve it in well-closed vessels.—Br.

In the process of the U. S. P., which is based on the suggestions of Dunstan and Short, sodium nitrite is decomposed by sulphuric acid, and the nitrous acid, in its nascent state, attacks the alcohol, forming ethyl nitrite and water, as shown by the following equation: $NaNO_2 + H_2SO_4 = HNO_2 + NaHSO_4$; $C_2H_5OH + HNO_2 = C_2H_5NO_2 + H_2O$. The newly-formed ethyl nitrite rises as an oily layer to the surface. In order that a large yield of ethyl nitrite may be insured, it is essential that the tube of the separator be allowed to reach nearly to the bottom of the flask containing the alcohol

and sulphuric acid mixture, and that the solution of sodium nitrite be allowed to flow into the flask very slowly in drops, the flask being kept thoroughly cold during the reaction. From the above equation it will be seen that 68.57 Gm. of absolute sodium nitrite are capable of yielding 74.51 Gm. of ethyl nitrite, and if the official salt (containing at least 90 per cent. of $NaNO_2$) be used, the 100 Gm. ordered in the official formula should be able to produce at least 97.79 Gm. of ethyl nitrite, which would yield 2151.38 Gm. of the official spirit. In practice there is always some loss, the full theoretical yield being never obtainable, and hence the necessity of ascertaining the exact weight of the purified ethyl nitrite in order to determine the final weight of alcohol to be added. In our experience the process is easy of execution, and with a little care very satisfactory results are obtained. The amount of pure ethyl nitrite recovered may vary from 70 to 80 Gm. from 100 Gm. of sodium nitrite, and, using such apparatus as are generally found in laboratories, with ordinary precaution we have obtained 78 Gm.

The second formula gives the process of Prof. Redwood (1867), and yields good results if proper attention be paid to the strength of the acids and the alcohol, and to the temperature; it is, however, best adapted for being worked on a small scale. The sulphuric acid, in the presence of nitric acid, dissolves the copper, forming sulphate of copper and setting nitrous acid free, which in its nascent state acts upon the alcohol, producing nitrous ether and water. The reaction is explained by the equation $C_2H_5OH + HNO_3 + H_2SO_4 + Cu = C_2H_5NO_2 + CuSO_4 + 2H_2O$.

Older formulas differ from Redwood's either in acting upon alcohol directly by nitric acid or in generating nitric acid from potassium nitrate and sulphuric acid in the presence of alcohol. In either case the result is much influenced by the strength of the acid and by the temperature, and a larger quantity of aldehyde is always thus produced than in the presence of copper. The action of nitric acid upon alcohol and the production of aldehyde are explained by the equation $2C_2H_5OH + HNO_3 = C_2H_4O + C_2H_5NO_2 + 2H_2O$. The German Pharmacopœia directs a mixture of 5 parts of alcohol and 3 of nitric acid to be set aside for 12 hours, and then distilled into 5 parts of alcohol. The resulting solution is neutralized with calcined magnesia, and after 24 hours again distilled, the distillate being collected in a flask containing 2 parts of alcohol, and the distillation being continued until the contents of the flask have increased to 8 parts. No requirement for a definite ethyl nitrite content is made, but it is stated that 10 Cc. of the finished product, after addition of 0.2 Cc. normal alkali solution, shall not show an acid reaction.

For some time manufacturing chemists have been offering ethyl nitrite in suitable tubes to be diluted with the necessary quantity of alcohol, so as to make spirit of nitrous ether in small quantities. While this plan is very convenient, and no doubt gives better results than much of the commercial article sold in bulk, it should be remembered that ethyl nitrite, unless absolutely free from alcohol and water, is likely to undergo decomposition. Pure ethyl nitrite is a thin, pale-yellow liquid, having a pungent, ethereal, apple-like odor. Since it boils at 16° C. (60.8° F.), it should be kept in a cool place, and the containers opened with care.

Properties and Tests.—Spirit of nitrous ether is a clear, mobile, volatile, and inflammable liquid of a pale yellowish or faintly greenish-yellow tint, having a fragrant, ethereal, and pungent odor, free from acidity, and a sharp, burning taste. Specific gravity: about 0.823 at 25° C. (77° F.). When freshly prepared, or even after being kept for some time with but little exposure to light and air, it is neutral to litmus paper. When long kept, or after having been freely exposed to air and light, it acquires an acid reaction, but it should not effervesce when a crystal of potassium bicarbonate is dropped into it. If a test-tube be half filled with the spirit, and put into a water-bath heated to 65° C. (149° F.) until it has acquired this temperature, the spirit should boil distinctly upon the addition of a few pieces of broken glass. If 10 Cc. of the spirit be mixed with 5 Cc. of potassium hydroxide test-solution, previously diluted with 5 Cc. of water, the mixture will assume a yellow color, which should not turn decidedly brown within 12 hours (limit of aldehyde).—U. S.

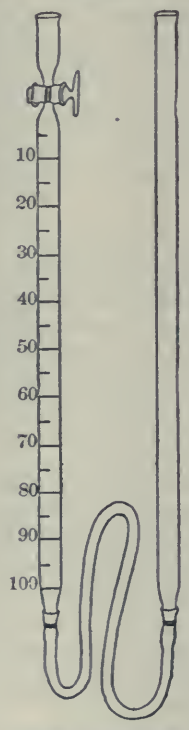
It should not effervesce, or only very feebly, when shaken with sodium bicarbonate (limit of acid); 1 volume agitated briskly at intervals during five minutes in a brine-charged nitrometer, with 1 volume of solution of potassium iodide and 1 volume of diluted sulphuric acid, should yield, at the normal temperature 15.6° C. (60° F.) and pressure (30 In. or 760 Mm. of mercury), and when freshly prepared, at least $6\frac{1}{4}$,

but not more than 7, volumes of nitric oxide gas, corresponding to at least 2½ parts by weight of ethyl nitrite in 100 parts by weight of the spirit; and even after it has been kept for some time, and the vessel containing it has occasionally been opened, it should yield not much less than 5 times its volume of the gas, corresponding to nearly 2 per cent. by weight of ethyl nitrite or a minimum of 1¾ per cent.—Br.

Assay for Ethyl Nitrite.—Transfer about 30 Gm. of the spirit of nitrous ether, which has been previously shaken with 0.5 Gm. of potassium bicarbonate, to a tared 100 Cc. measuring flask, and weigh it accurately. Add sufficient alcohol to bring the volume to exactly 100 Cc., and mix thoroughly. Introduce into a nitrometer exactly 10 Cc. of the alcohol solution, followed by 10 Cc. of potassium iodide test-solution, and afterwards by 10 Cc. of normal sulphuric acid solution. When the volume of gas has become constant (within 30 to 60 minutes), note the volume of gas collected. Multiply this volume in Cc. by 0.307, and divide the product by the original weight of the spirit of nitrous ether. At standard temperature and pressure, the quotient will represent the percentage of ethyl nitrite in the liquid. The temperature correction is ⅓ of 1 per cent. of the total percentage just found for each degree, additive if temperature is below, subtractive if above, 25° C. (77° F.). The barometric correction is $\frac{4}{30}$ of 1 per cent. for each millimeter, additive if above, subtractive if below, 760. When assayed according to the above method, spirit of nitrous ether should yield not less than 4 per cent. of ethyl nitrite.—U. S.

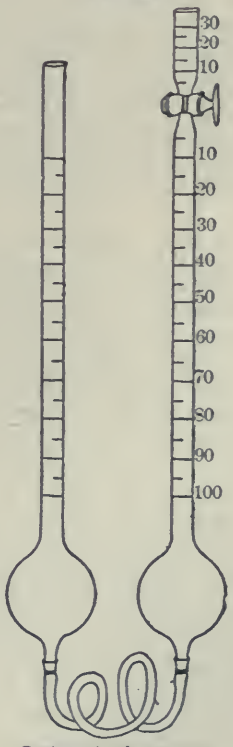
The official assay method is based on the suggestions of the late A. H. Allen (1885), and is much simpler than other methods in use prior to that time. The nitrometer (see Figs. 407 and 408) is completely filled with saturated solution of sodium chloride,

Fig. 407.



Lunge's nitrometer.

Fig. 408.



Curtman's nitrometer.

including the bore of the glass stopcock, and care must be observed that no air enter while the different liquids are allowed to flow from the cup into the nitrometer; this is best avoided by washing the cup with a few Cc. of alcohol or salt solution after the other liquids have been run into the tube, and allowing 0.2 or 0.3 Cc. of fluid to remain in the cup.

The reaction which takes place in the official assay may be shown by the following equation: $C_2H_5NO_2 + KI + H_2SO_4 = C_2H_5OH + KHSO_4 + I + NO$, from which it

appears that 29.81 Gm. of NO gas correspond to 74.51 Gm. of ethyl nitrite. At 0° C. (32° F.) and 760 Mm. pressure, 1 Cc. of NO gas weighs 0.0013355 Gm., but under the conditions mentioned in the assay method, 25° C. (77° F.) and 760 Mm. pressure it weighs 0.0012297 Gm., and hence the amount of ethyl nitrite corresponding to 1 Cc. of NO gas at the temperature and pressure last mentioned will be found to be 0.0030736 Gm., as shown by the following proportion: 29.81 : 74.51 :: 0.0012297 : x (x = 0.0030736). Hence if we let *W* represent the original weight of spirit of nitrous ether involved in the assay (which must be $\frac{1}{10}$ of the weight of the spirit before dilution to 100 Cc.), and *N* the number of Cc. of NO gas obtained in the assay, then ($N \times 0.0030736$) ÷ W represents the weight of absolute ethyl nitrite contained in 1 Gm. of the sample. The amount in 100 Gm. of the spirit or the percentage will be ($N \times 0.0030736 \times 100$) ÷ *W* or ($N \times 0.30736$) ÷ W, which is the rule given in the Pharmacopœia, where the factor 0.30736 has been abbreviated to 0.307.

If the volume of NO gas had a temperature above or below that given in the Pharmacopœia, 25° C. (77° F.), a correction is necessary in the results obtained by the above calculation, the latter applying only to the official temperature. Above 25° C. the volume of NO gas as read is larger than it would be at 25° C., and therefore the per cent. of ethyl nitrite appears greater than is actually true, and a fraction must be subtracted corresponding to the excess of volume of the NO gas over the volume it would have at 25° C. By similar reasoning it follows that when the temperature is below 25° C. a correction must be added corresponding to the deficiency of volume of the NO gas as compared with the volume it would have at 25° C. From Gay-Lussac's law of the relation of gas volumes to their absolute temperatures, the difference between the volume of the NO gas as actually read and what it would be at 25° C. may be calculated. Let t = the temperature at which the NO gas was actually read. Then by the law of expansion 1 Cc. of NO gas at t : *x* Cc. at 25° C. :: 273 + t : 273 + 25 or $x = \frac{273 + 25}{273 + t}$; that is, 1 Cc. of NO gas at t° C. would become $\frac{273 + 25}{273 + t}$ Cc. at 25° C. The correction in volume for each Cc. of NO gas as read at t° C., thus becomes $\left(1 - \frac{273 + 25}{273 + t}\right)$ Cc. $= \left(\frac{t - 25}{273 + t}\right)$ Cc. when it is greater than 25°C., or $\left(\frac{273 + 25}{273 + t} - 1\right)$ Cc. $= \left(\frac{25 - t}{273 + t}\right)$ Cc. when it is less than 25° C. When the temperature t is only a few degrees above or below 25° C. the denominator of these fractions is approximately 300, so that they become $\frac{1}{300}$, $\frac{2}{300}$, $\frac{3}{300}$, etc., according as the difference between temperature t of measurement of the NO gas and 25° C. is 1, 2, 3, etc., degrees. As each Cc. of NO gas measured in the assay is too great or too small by $\frac{1}{300}$ part for each degree of temperature above or below the official temperature, fixed at 25° C., it follows that the per cent. as first calculated must be corrected by $\frac{1}{300}$ (*i. e.*, $\frac{1}{3}$ of 1 per cent.), as given in the Pharmacopœia. This correction deviates more and more from the truth as the temperature difference becomes greater.

If the pressure under which the NO gas is measured is not 760 Mm. of mercury, which is the one assumed in the assay formula for calculation, the volume is either too large or too small, and therefore the per cent. of ethyl nitrite found also. If we let *p* = pressure in Mm. of mercury under which the NO gas is measured, then, according to Boyle's law—namely, that the product of the volume and pressure of a gas is always constant, 1 Cc. NO gas × *p* = x Cc. NO × 760, or x = (1 Cc. × *p*) ÷ 760—that is, 1 Cc. NO measured at any other pressure, *p*, would be $\frac{p}{760}$ Cc. at normal barometric pressure, 760 Mm. The correction in volume for each Cc. NO gas measured at pressure *p* is $\left(1 - \frac{p}{760}\right)$ Cc. or $\frac{760 - p}{760}$ Cc., when *p* is less than 760, or $\frac{p - 760}{760}$ Cc. when *p* is greater than 760. When *p* is greater than 760 the gas is under too great a pressure, that is, the volume is less than it should be, hence a correction should be added to the calculated per cent. as first found in the official method of calculation. When *p* is less than 760 the correction must be subtracted. According as the pressure is 1, 2, 3, etc., Mm. of mercury above or below the normal, 760 Mm., the correction for each Cc. of NO gas will amount to 1, 2, 3, etc., times $\frac{1}{760}$, and the correction of the per cent. must be the same number of times $\frac{1}{760}$ of that first found. $\frac{1}{760}$ is sufficiently close to

$\frac{1}{750}$ or $\frac{4}{3}\frac{1}{0}$ of $\frac{1}{100}$, which means $\frac{4}{3}\frac{1}{0}$ of 1 per cent., as given in the Pharmacopœia. This correction, as in the case of temperature, is only a close approximation, and must not be construed as absolute.

Preservation.—Spirit of nitrous ether should never be kept in large or partially filled bottles, nor exposed to light, as it thus rapidly undergoes oxidation and becomes worthless; neither should it be purchased in bulk, as it is impossible to preserve the quality of it when kept in carboys or large bottles which are frequently opened and rarely securely stoppered. We have frequently examined samples of spirit of nitrous ether drawn from carboys in the cellar of wholesale drug-houses, and found them far below the official requirements, often as low as $\frac{1}{4}$ or $\frac{1}{2}$ per cent. of ethyl nitrite. Even if carefully protected against air and light, the solution slowly decomposes and becomes gradually weaker.

Action and Uses.—Spirit of nitrous ether possesses valuable diuretic and diaphoretic properties, and is, in addition, a sedative to the circulation and nervous system. If its vapor be inhaled in sufficient quantity it produces flushing of the face, giddiness, severe throbbing headache, nausea, muscular relaxation, a rapid, irregular pulse, and dyspnœa. The symptoms resemble those which follow the inhalation of amyl nitrite. In febrile affections, especially of a milder type in children, no remedy at our command so readily cools the skin, quiets nervous excitement, and produces a sense of well-being than sweet spirit of nitre. Because of these excellent properties it is popular as a household medicine. A full dose, followed by a drink of hot lemonade, will frequently abort a forming "cold." When given the patient should be in bed and well-blanketed to promote free diaphorsesis. As a diuretic, spirit of nitre is applicable to the early stage of acute renal inflammation, and to relieve irritation of the urinary tract and bladder due to concentrated urine from any cause. Its diuretic effect is enhanced by the addition of the alkaline salts of vegetable acids, as citrates, acetates, and tartrates. It may be given in full doses for angina pectoris when other nitrites cannot be easily obtained. The dose of spirit of nitrous ether in febrile affections is 20 to 30 minims (1.30–2 Cc.) every 1 or 3 hours. As a diuretic, 30 to 60 minims (2–4 Cc.) should be given every 2 to 4 hours in cold water. Given in hot water its diaphoretic effect is more pronounced.

SPIRITUS AMMONIÆ, *U. S.*—Spirit of Ammonia.

Liquor ammonii caustici spirituosus; Spiritus ammoniaci caustici Dzondii.—Ammoniated alcohol, E.; *Alcoolat ammoniacal, Liqueur d'ammoniaque vineuse*, Fr.; *Weingeistiges Ammoniak*, G.

An alcoholic solution of ammonia ($NH_3 = 16.93$) containing 10 per cent. by weight of the gas. This solution deteriorates on keeping, and should be tested frequently. It must not be dispensed for medicinal purposes if it contains less than 10 per cent. of gaseous ammonia.—U. S.

Preparation.—Stronger ammonia-water 250 Cc.; alcohol, recently distilled and which has been kept in glass vessels, a sufficient quantity. Pour the stronger water ammonia into a flask provided with a safety funnel, and connected by means of a glass condenser with a well-cooled receiver, containing 500 Cc. of alcohol, the delivery tube of the condenser reaching nearly to the bottom of the receiver. Heat the flask carefully and very gradually to a temperature not exceeding 60° C. (140° F.), and maintain it at that temperature until ammonia ceases to be evolved. Then disconnect the receiver, and, having ascertained the strength of a portion of the contents by the method of assay given below, add enough alcohol to make the product contain 10 per cent. by weight of ammonia gas. Keep the product in glass-stoppered bottles in a cool place.—U. S.

250 Cc. of stronger ammonia-water of full strength, weighing 225.25 Gm., contain 56.3 Gm. of ammonia, one-half of which is readily given off at a temperature not exceeding 45° C. (113° F.); but 41 Gm. of ammonia being required for 500 Cc. of alcohol, a somewhat higher heat is required, which, however, should not exceed 60° C. (140° F.). After the evolution of ammonia ceases, the ammoniacal alcohol (2 Cc.) is tested with sulphuric acid in the manner directed by the Pharmacopœia, and if more than 19.1 Cc. of the half-normal acid are needed for neutralization, the alcohol required for dilution is readily calculated; but if the liquid becomes neutral with a smaller

quantity of the volumetric solution, the alcohol should be further charged with ammonia gas evolved from a fresh portion of strong ammonia-water; increasing the heat is inadmissible, since too large a proportion of water would pass over. Alcohol which has been kept in a barrel is apt to contain more or less organic matter in solution, which would be darkened in color by ammonia; hence the recommendation to use only alcohol which after rectification has been preserved in glass vessels.

Properties.—Spirit of ammonia is a colorless liquid having a strong ammoniacal and at the same time spirituous odor and a specific gravity of about 0.808 at 25° C. (77° F.). When diluted with water it has the same behavior to reagents as ammonia-water, and its purity and identity may be determined in the same manner as for the latter.

Assay of Spirit of Ammonia.—Introduce into a weighing bottle about 2 Cc. of the Spirit, weigh accurately, dilute with 50 Cc. of distilled water, and titrate with half-normal sulphuric acid solution, using litmus test solution as indicator. Multiply the number of Cc. of half-normal sulphuric acid solution consumed by 0.008465, and this product by 100, and divide by the weight in grammes of the spirit taken to obtain the percentage of ammonia gas.—U. S.

Uses.—Spirit of ammonia is stimulant and antispasmodic. It is rarely used, having been supplanted by the more agreeable aromatic spirit. (See SPIRITUS AMMONIÆ AROMATICUS.) Its dose is from 10 to 30 minims (0.60–2 Cc.), well diluted.

SPIRITUS AMMONIÆ AROMATICUS, *U. S., Br.*—Aromatic Spirit of Ammonia.

Alcoolat ammoniacal aromatique, Fr.; *Aromatischer Ammoniakgeist*, G.

Preparation.—Ammonium carbonate, in translucent pieces, 34 Gm.; ammonia-water 90 Cc.; oil of lemon 10 Cc., oil of lavender-flowers 1 Cc.; oil of nutmeg 1 Cc.; alcohol, 700 Cc.; distilled water a sufficient quantity; to make 1000 Cc. To the ammonia-water, contained in a flask, add 140 Cc. of distilled water, and afterward the ammonium carbonate reduced to a moderately fine powder. Close the flask and agitate the contents until the carbonate is dissolved, and allow it to stand for 12 hours. Introduce the alcohol into a graduated bottle of suitable capacity, add the oils, then gradually add the solution of ammonium carbonate, and afterward enough distilled water to make the product measure 1000 Cc. Set the liquid aside during 24 hours in a cool place, occasionally agitating, then filter it through paper in a well-covered funnel. Keep the product in glass-stoppered bottles in a cool place.—U. S.

Oil of nutmeg 4½ fluidrachms, oil of lemon 6½ fluidrachms, alcohol 6 pints, water 3 pints; distil 149 fluidounces. Place the last 9 ounces of distillate in a bottle with ammonium carbonate 4 ounces and strong ammonia solution 8 fluidounces; warm gently to 140° F. until dissolved; filter through cotton and gradually mix with the distillate.—Br.

On adding ammonia-water to official ammonium carbonate, normal ammonium carbonate is formed, which is readily soluble in alcohol. This is the compound aimed at by both Pharmacopœias. If official ammonium carbonate is treated with alcohol, normal ammonium carbonate will be dissolved, and acid ammonium carbonate, being nearly insoluble, will be left behind. An insoluble saline precipitate will therefore indicate either a deficiency in the strength of the ammonia-water or a partial decomposition of the carbonate used. This salt should be employed only in translucent masses, and the effloresced portion, which contains variable proportions of acid ammonium carbonate, should be rejected for this preparation. In order to ensure the complete change of the ammonium salt, we have found it advantageous to allow the mixture of ammonium carbonate, distilled water, and ammonia-water to stand for some time (say 12 hours) before mixing it with the alcoholic solution of the oils. The change effected is readily explained as follows: $NH_4HCO_3.NH_4NH_2CO_2$ (official carbonate) + NH_4OH (ammonia) = $2(NH_4)_2CO_3$ (normal carbonate).

Properties.—This spirit is nearly colorless when freshly prepared, but gradually acquires a somewhat darker tint. It has an aromatic and at the same time pungent ammoniacal odor and taste, effervesces with acids, becomes milky on the addition of water, and has the specific gravity about 0.900 at 25° C. (77° F.) U. S. or 0.888 to 0.893.—Br.

Uses.—Aromatic spirit of ammonia is more agreeable to the taste than the simple spirit, and more generally employed. Its properties are stimulant, antispasmodic, and antacid. It is extensively used for the relief of headache attended with nausea, acid eructations, and flatulence. It may be administered with excellent results in cases of profound shock and sudden failure of the vital functions, and is one of the best diffusible stimulants that we have: The dose is from ½ to 1 drachm (2–4 Cc.), properly diluted with water.

SPIRITUS AMMONIÆ FŒTIDUS, *Br.*—Fetid Spirit of Ammonia.

Alcoolat ammoniacal fétide, Essence antihystérique, Fr.; *Ammoniakalischer Stinkasantgeist*, G.

Preparation.—Take of asafetida 1½ ounces; strong solution of ammonia, 2 fluidounces; alcohol (90 per cent.), a sufficient quantity. Break the asafetida into small pieces and macerate it, in a closed vessel, in 15 fluidounces of the alcohol for 24 hours; distil until alcoholic vapors cease to be condensed; mix the distillate with the solution of ammonia, and add sufficient alcohol to make 1 pint (imperial).—Br.

On distilling the tincture of asafetida prepared as above directed, a portion of the volatile oil of asafetida passes over; the finished preparation is therefore an alcoholic solution of this volatile oil mixed with ammonia-water. *Aqua fœtida antihysterica* (*s. Pragensis*) is a weak distilled spirit free from ammonia, but contains the volatile products of galbanum, myrrh, valerian, zedoary, angelica, peppermint, wild thyme, English chamomile, and castor, in addition to the oil of asafetida.

Uses.—This preparation is designed to exhibit the stimulant and antispasmodic properties of asafetida and ammonia, and is indicated in hysterical conditions and functional nervous disorders. The dose is ½ to 1 drachm (2–4 Cc.).

SPIRITUS AMYGDALÆ AMARÆ, *U. S.*—Spirit of Bitter Almond.

Essence of bitter almond, E.; *Alcoolat (Esprit) d'amandes amères*, Fr.; *Bittermandelgeist*, G.

Preparation.—Oil of bitter almond, 10 Cc.; alcohol, 800 Cc.; distilled water, a sufficient quantity; to make 1000 Cc. Dissolve the oil in the alcohol, and add enough distilled water to make the product measure 1000 Cc.—U. S.

Uses.—Spirit of bitter almond is used as a flavoring agent.

SPIRITUS ANGELICÆ COMPOSITUS, *P. G.*—Compound Spirit of Angelica.

Alcoolat d'angélique composé, Fr.; *Zusammengesetzter Angelikaspiritus*, G.

Preparation.—Take of angelica (root), in moderately fine powder, 16 parts; valerian (root), in moderately fine powder, 4 parts; juniper berries, crushed, 4 parts; alcohol, 75 parts; water, 125 parts. Mix the alcohol and water, add the drugs, and set the mixture aside at a temperature of 15° to 20° C. (59°–68° F.) for 24 hours, with occasional agitation. Then distil 100 parts, and in the distillate dissolve camphor, 2 parts.—P. G.

Compound spirit of angelica is a clear, colorless liquid, having the specific gravity of 0.890 to 0.900.

Uses.—This preparation combines antispasmodic and stimulant properties, and may be given in nervousness of hysterical origin. Its dose is from ½ to 1 drachm (2–4 Cc.).

SPIRITUS ANISI, *U. S., Br.*—Spirit of Anise.

Alcoolat (Esprit) d'anis, Fr.; *Anisgeist*, G.

Preparation.—Oil of anise, 100 Cc.; alcohol, 900 Cc.; to make 1000 Cc. Mix them.—U. S.

The formula of the British Pharmacopœia is identical with the above.

Uses.—Spirit of anise is carminative and antispasmodic in the dose of 1 to 2 drachms (4–8 Cc.). It is also used to flavor mixtures.

SPIRITUS ARMORACIÆ COMPOSITUS, *Br.*—Compound Spirit of Horseradish.

Esprit de raifort composée, Alcoolat antiscorbutique, Fr.; *Meerrettiggeist,* G.

Preparation.—Take of horseradish-root, scraped, bitter orange-peel, well bruised, each 5 ounces; nutmeg, bruised, 55 grains; alcohol (90 per cent.), 1¼ pints; distilled water, 1½ pints. Mix and distil 2 pints (imperial).—Br.

This preparation is an alcoholic solution of the volatile oils of the drugs used.

Uses.—This compound is a useful addition to other diuretic preparations, to be given especially in those cases in which stimulating diuretics are indicated in cases of renal inactivity not due to acute inflammation. Its dose from 1 to 2 drachms (4–8 Cc.) diluted.

SPIRITUS AURANTII COMPOSITUS, *U. S.*—Compound Spirit of Orange.

Esprit d'orange composée, Fr.; *Zusammengesetzter Orangengeist,* G.

Preparation.—Oil of orange-peel, 200 Cc.; oil of lemon, 50 Cc.; oil of coriander, 20 Cc; oil of anise, 5 Cc.; alcohol, a sufficient quantity; to make 1000 Cc. Mix them. Keep the product in completely filled, well-stoppered bottles in a cool and dark place. —U. S.

To make 1 pint of compound spirit of orange dissolve 3 fluidounces and 96 minims of oil of orange-peel, 384 minims of oil of lemon, 154 minims of oil of coriander, and 39 minims of oil of anise, in sufficient alcohol to make 16 fluidounces of solution.

Uses.—Compound spirit of orange is used chiefly for its agreeable taste. It is the principal ingredient of aromatic elixir. It is given in doses of from ½ to 1 drachm (2–4 Cc.) diluted.

SPIRITUS CAJUPUTI, *Br.*—Spirit of Cajuput.

Alcoolat (Esprit) de cajeput, Fr.; *Cajeputgeist,* G.

Preparation.—Take of oil of cajuput 1 fluidouuce; alcohol (90 per cent.), a sufficient quantity to form 10 fluidounces of the spirit. Dissolve.—Br.

Uses.—The uses of this spirit are the same as of the oil of cajuput. The dose is 30 to 60 minims (2–4 Cc.) diluted.

SPIRITUS CAMPHORÆ, *U. S., Br.*—Spirit of Camphor.

Teinture de camphre concentrée, Fr. Cod.; *Spiritus camphoratus,* P. G.; *Tinctura camphoræ.—Tincture of camphor,* E.; *Esprit de camphre, Alcool camphré,* Fr.; *Kampherspiritus,* G.

Preparation.—Camphor, 100 Gm.; alcohol, a sufficient quantity; to make 1000 Cc. Dissolve the camphor in 800 Cc. of alcohol, filter through paper, and pass enough alcohol through the filter to make the product measure 1000 Cc.—U. S.

To make 1 pint of spirit of camphor dissolve 1¾ avoirdupois ounces of camphor in 12 fluidounces of alcohol, and add to the solution sufficient alcohol to bring the volume up to 16 fluidounces.

Take of camphor 1 ounce; alcohol (90 per cent.) sufficient to make 10 fluidounces. Dissolve.—Br.

Dissolve 1 part of camphor in 9 parts of alcohol.—Fr. Cod.

Dissolve 1 part of camphor in 7 parts of alcohol, and to the solution add 2 parts of water.—P. G.

Uses.—This preparation is useful chiefly when it is desired to apply camphor locally for sprains, bruises, headache, and other painful conditions. It may be used as a local application to wounds and indolent ulcers. Internally administered, it is antispasmodic and sedative. The dose is from 5 to 30 minims (0.30–2 Cc.) diluted.

SPIRITUS CHLOROFORMI, *U. S., Br.*—Spirit of Chloroform.

Chloric ether, Spirit of chloric ether, E.; *Alcoolat de chloroforme,* Fr.; *Chloroformspiritus,* G.

Preparation.—Chloroform, 60 Cc.; alcohol, 940 Cc.; to make 1000 Cc. Mix them.—U. S.

To make 1 pint of spirit of chloroform mix 461 minims of chloroform with sufficient alcohol to bring the volume up to 16 fluidounces. Each fluidounce contains nearly 30 minims (28.8 +) of chloroform.

Chloroform 1 fluidounce; alcohol (90 per cent.) 19 fluidounces; dissolve.—Br.

Uses.—This is a convenient preparation for administering chloroform by the stomach. It may be given in colic and other painful conditions of the abdomen. The dose is from 20 to 60 minims (1.30–4 Cc.) diluted with water.

SPIRITUS CINNAMOMI, *U. S., Br.*—Spirit of Cinnamon.

Alcoolat de cannelle, Fr.; *Zimmtspiritus*, G.

Preparation.—Oil of cinnamon, 100 Cc.; alcohol, 900 Cc.; to make 1000 Cc. Mix them.—U. S.

Oil of (Ceylon) cinnamon 1 fluidounce; alcohol (90 per cent.) 9 fluidounces.—Br.

Uses.—Spirit of cinnamon may be used to promote digestion, to relieve intestinal colic, and to flavor various mixtures. Its dose is from 10 to 20 minims (0.60–1.30.).

SPIRITUS COCHLEARIÆ, P. G.—Spirit of Scurvy-grass.

Alcoolat de cochléaria, F.; *Löffelkrautspiritus*, G.

Preparation.—Take of cochlearia (herb) 4 parts; white mustard seed, ground, 1 part. Place the drugs into a retort, add water 40 parts, and macerate for 3 hours; then add alcohol 15 parts, mix and distil 20 parts.—P. G.

Properties and Tests.—Spirit of scurvy-grass is a clear, colorless liquid, having a characteristic odor and a pungent taste. Its specific gravity ranges from 0.908 to 0.910. If 50 Cc. of the spirit be added to 10 Cc. of tenth-normal silver nitrate solution and 5 Cc. of ammonia-water in a 100 Cc. measuring cylinder, covered and set aside for twenty-four hours with frequent agitation, and after bringing the volume up to 100 Cc. by addition of water, filtered, 50 Cc. of the clear filtrate, after addition of 3 Cc. of nitric acid and 1 Cc. of ammonium ferric sulphate solution, should require 2.2 to 2.5 Cc. of tenth-normal ammonium sulphocyanate solution to produce a red coloration.—P. G.

Uses.—This preparation may be used as a stimulating application to painful joints. Internally it is stimulant and diuretic. The dose is from 20 to 40 minims (1.30–2.60 Cc.).

SPIRITUS FRUMENTI, *U. S.*—Whisky.

Eau de vie de grains, Fr.; *Kornbranntwein*, G.

An alcoholic liquid obtained by the distillation of the mash of fermented grain—such as Indian corn, rye, wheat, and barley, or their mixtures.

Origin and Preparation.—The term "whisky" is supposed to be derived from *usque*, the first two syllables of *usquebaugh*, the original name in Ireland—itself from Irish *uisge* and *beatha*, "life," *Uisge beatha, Aqua vitæ*, "Water of Life" (Dunglison's *Dictionary*). In Europe whisky is often made by fermenting potatoes, but likewise from different kinds of grain; in Great Britain principally from barley, oats, and rye. In the United States rye, maize, and wheat are mostly employed for the manufacture of whisky either in the raw state or after having been previously malted, when it furnishes a product of better flavor. The fermenting mixture is called the *mash*. During the fermentation the starch is converted into sugar, and finally into alcohol and carbon dioxide. The mixture is now subjected to distillation, and the weak spirit, called *low wine*, is rectified, and thus obtained stronger and less charged with fusel oil, which comes over chiefly in the last portions of the distillate. The *raw whisky* is kept in barrels or tanks for several years, during which time it acquires mellowness and is improved in flavor, doubtless in consequence of the formation of various compound ethers.

Properties.—Whisky is a spirituous liquid, usually of a yellowish or amber color, due to coloring matter and to a trace of tannin derived from the tanks in which it has been kept, and to a trace of sugar which has probably been added in the form of caramel. The density of whisky depends on the percentage of alcohol, and is to a slight extent influenced by the amount of the coloring and extractive matters; it should be

not above 0.945, nor less than 0.924 at 15.6° C. (60° F.), corresponding, approximately, to an alcoholic strength of 37 to 47.5 per cent. by weight or 44 to 55 per cent. by volume of absolute alcohol. The disagreeable odor of raw whisky is mainly owing to a small quantity of amylic alcohol, which on keeping is changed into an ether, and perhaps partly into valerianic acid; œnanthylic and other allied acids are likewise present to a slight extent. Old whisky has a slight acid reaction, due to the formation of a minute quantity of acetic and, according to Kappel (1859), of valerianic acid. For neutralizing the acidity of good whisky 20 Cc. require usually between 0.8 and 1.0 Cc. of tenth-normal solution of alkali, indicating between 0.113 and 0.142 Gm. of acetic acid or its equivalent. The acidity slowly increases with age up to a certain degree; in one case 2.25 Cc. of tenth-normal alkali were required for 20 Cc. of whisky.

Tests.—On evaporating whisky by a moderate heat nearly to dryness, the residue which is left should have a slightly aromatic and rather insipid, but not an acrid, taste. The most convenient test for recognizing the origin of whisky is that proposed by Molnar. A small quantity of it is heated with a slight excess of potassium hydroxide until the alcohol has been completely evaporated; the compound ethers are thereby decomposed, and on adding an excess of sulphuric acid the volatile acids are liberated, and from their odor the source is recognized. *Apple whisky* distilled from cider gives off a decided fruit odor; the odors of whiskies of different kinds of grain are sufficiently distinct from one another, but to readily recognize them considerable experience is required. "If 100 Cc. of whisky be very slowly evaporated in a weighed capsule on a water-bath, the last portions volatilized should not have a harsh or disagreeable odor (absence of more than traces of fusel oil from grain). The remaining residue, fully dried at 100° C. (212° F.), should weigh not more than 0.25 Gm. This residue should have no sweet or distinctly spicy taste (absence of added sugar, glycerin, or spices). It should nearly all dissolve in 10 Cc. of cold water, forming a solution which is colored not deeper than light-green by a few drops of ferric chloride test-solution diluted with 10 volumes of water (absence of more than traces of oak tannin from casks). If 50 Cc. of whisky be shaken vigorously in a stoppered flask with 25 Gm. of kaolin, and, after standing half an hour, be filtered, the color of the filtrate should not be lighter than that of the whisky before treatment (absence of caramel coloring). 100 Cc. of whisky should be rendered distinctly alkaline to litmus by 1.2 Cc. of normal potassium hydroxide solution (limit of free acid)."—U. S.

Uses.—The physiological action of whisky is considered under Alcohol. Whisky is more easily obtained unadulterated than is brandy, and for this reason is preferred for most medicinal purposes. The dose is from 1 to 4 ounces (30–120 Cc.).

SPIRITUS GAULTHERIÆ, *U. S.*—Spirit of Gaultheria.

Alcoolat (Esprit) de gaulthérie, Fr.; *Bergtheespiritus (geist)*, G.

Preparation.—Oil of gaultheria: 50 Cc.; alcohol, 950 Cc.; to make 1000 Cc. Mix them.—U. S.

"Essence of wintergreen" has been in use for a long time, but was prepared of varying strength. The pharmacopœial formula is intended to accomplish uniformity.

Uses.—Spirit of gaultheria is used chiefly to impart its agreeable odor and taste to mixtures. Its dose is from 10 to 20 minims (0.60–1.30 Cc.) diluted.

SPIRITUS GLYCERYLIS NITRATIS, *U. S.*—Spirit of Glyceryl Trinitrate.

Spiritus glonoini, U. S., 1890.—*Spirit of glonoin, Spirit of nitroglycerin, Solution of nitroglycerin*, E.; *Nitroglyceringeist, Glycerintrinitratlösung*, G.

An alcoholic solution containing 1 per cent., by weight, of glyceryl trinitrate ($C_3H_5(O.NO_2)_3 = 225.44$). Spirit of glyceryl trinitrate should be kept and transported in well-stoppered tin cans, and should be stored in a cool place, remote from lights or fire. Great care should be exercised in handling, packing, transporting, or storing the spirit, since a dangerous explosion may result if any considerable quantity of it be spilled and the alcohol be partly or wholly lost by evaporation. If, through accident, it be spilled, a solution of potassium hydroxide should be at once poured over it to effect decomposition.—U. S.

Properties and Tests.—"A clear, colorless liquid, possessing the odor and taste of alcohol. Caution should be exercised in tasting it, since even a small quantity of it is liable to produce a violent headache. The same effect is produced when it is freely applied to the skin. It is neutral to litmus-paper. Specific gravity 0.814 to 0.820 at 25° C. (77° F.). On diluting 10 Cc. of the spirit with 15 Cc. of water, both liquids, as well as the mixture, being brought to 15° C. (59° F.), the liquid will exhibit at most a faint cloudiness, but the addition of a further portion of 5 Cc. of water should produce a white turbidity. If the specific gravity of the spirit be higher than 0.830 at 25° C. (77° F.), or if 10 Cc. of it are rendered turbid by less than 10 Cc. of water, the spirit should be rejected.—U. S.

Preparation of Glyceryl Trinitrate.—This compound, generally, but wrongly, called nitroglycerin and also known as trinitrin, glonoin, and propenyl trinitrate, was discovered by Sobrero (1847), and may be prepared either by gradually adding 7 parts of dehydrated glycerin to a well-cooled solution of 20 parts of sodium nitrate in 40 parts of sulphuric acid, specific gravity 1.840, the mixture being kept cool, or 1 part of glycerin may be slowly added, with frequent stirring, to 7 parts of a mixture composed of 1 part of nitric acid, specific gravity 1.47, and 2 parts of strong sulphuric acid, the temperature being carefully kept below 26.6° C. (80° F.). The reaction taking place by either process, between the nitric acid and glycerin, results in the production of propenyl or glyceryl trinitrate: thus $C_3H_5(OH)_3 + 3HNO_3 = C_3H_5(NO_3)_3 + 3H_2O$. In either case the glyceryl trinitrate separates in the form of an oily layer, and is then washed with water, and finally with very dilute soda solution, until all acid reaction ceases. The product amounts to about two and one-third times the weight of glycerin employed. It is a colorless or pale-yellowish oily liquid of 1.60 specific gravity, and crystallizes when cooled to —20° C. (—4° F.). It may be freed from water by treatment with 10 per cent. of glycerin, in which the ester is insoluble, although it is miscible in all proportions with ether, chloroform, phenol, and glacial acetic acid. 1 Gm. of glyceryl trinitrate requires for solution 3.5 Cc. absolute alcohol, 10 Cc. alcohol, specific gravity 0.830, 18 Cc. methyl or amyl alcohol, 120 Cc. carbon disulphide or 800 Cc. water. It is without odor, but its vapors produce intense headache; its taste is sweet and pungently aromatic. When ignited in the open air it burns quietly and incompletely, but when heated in closed vessels or by percussion, it explodes with great violence; sometimes it explodes spontaneously. Nitroglycerin forms the basis of various blasting compounds known as *dynamite, giant-powder, glyoxylin, dualin,* etc. According to A. Nobel, 1 volume yields upon explosion about 10,400 volumes of gas.

Action and Uses.—Although a nitrate, the physiological action of nitroglycerin closely resembles that of the nitrites. The explanation given for this phenomenon seems to be that the glyceryl trinitrate is broken up, either in the alkaline secretion of the intestine or in the blood, into a mixture of nitrites and nitrates, the former of which exercises the dominant influence. As regards the rapidity of its action, it is intermediate to amyl nitrite and the nitrites of sodium and potassium. Its effect, which lasts 3 or 4 hours, is not as violent or fleeting as that of amyl nitrite, nor as persistent as of the alkaline nitrites. Glyceryl trinitrate may be employed in nearly all cases in which amyl nitrite is indicated, especially in angina pectoris accompanied by marked arterial spasm, and in asthma dependent upon spasm and enlargement of the bronchial tubes. Its most important application is to relieve the cardiac embarrassment consequent to the high arterial tension found in many cases of chronic interstitial nephritis. It was recommended by J. M. DaCosta as a remedy to decrease the excretion of albumin in chronic parenchymatous nephritis. Because nitroglycerin relaxes arterial tension and thus relieves the heart of a certain amount of labor in cases characterized by high vascular tension, and allows it to beat more forcibly and regularly, it has been considered a cardiac stimulant, but this employment of nitroglycerin as a cardiac stimulant in shock or collapse is not justified by a knowledge of its action on the heart or bloodvessels, it being a depressant rather than a stimulant. Nitroglycerin is claimed to be a valuable drug in many cases of vomiting. Given in the dose of $\frac{1}{200}$ grain (0.0003 Gm.) hypodermically, with morphine, it will prevent the nausea usually produced by that drug. The dose of the spirit of glyceryl trinitrate is ordinarily 1 to 2 minims (0.05–0.10 Cc.), but in interstitial nephritis it is commonly given in ascending doses until the desired result is obtained or untoward symptoms appear. More than 1 drachm (4 Cc.) has been taken 3 times a day with no ill effects.

SPIRITUS JUNIPERI, *U. S., Br.*—Spirit of Juniper.

Alcoolat (Esprit) de genièvre, Fr.; *Wachholderspiritus*, G.

Preparation.—Oil of juniper, 50 Cc.; alcohol, 950 Cc. to make 1000 Cc. Mix them.—U. S.

Oil of juniper, 1 fluidounce; alcohol (90 per cent.), 19 fluidounces; dissolve.—Br.

Macerate for twenty-four hours 1 part of bruised juniper-berries with 3 parts each alcohol and water, and distil 4 parts.—P. G.

The spirit made from the volatile oil distilled from juniper-berries is much more agreeable than if the common oil of juniper is used. Age improves the flavor.

Uses.—This preparation is added to diuretic mixtures used in the treatment of dropsy. Its dose is from 30 to 60 minims (2–4 Cc.).

SPIRITUS JUNIPERI COMPOSITUS, *U. S.*—Compound Spirit of Juniper.

Alcoolat de genièvre composé, Fr.; *Zusammengesetzter Wachholderspiritus*, G.

Preparation.—Oil of juniper, 8 Cc.; oil of caraway, 1 Cc.; oil of fennel, 1 Cc.; alcohol, 1400 Cc.; water, a sufficient quantity to make 2000 Cc. Dissolve the oils in the alcohol, and gradually add enough water to make the product measure 2000 Cc.—U. S.

To make 1 pint of compound spirit of juniper dissolve 30 minims of oil of juniper and 4 minims each of oil of fennel and oil of caraway in 11¼ fluidounces of alcohol, and gradually add enough water to bring the volume up to 16 fluidounces.

This spirit is an official substitute for *gin*, a spirit distilled in some parts of Europe from juniper-berries, to which sometimes other aromatics are added. It has the advantage of uniformity of composition over the commercial article, and if good volatile oils are used the flavor is agreeable and will improve by age.

Uses.—This preparation resembles Holland gin. It is given in dropsy of both cardiac and renal origin, and is usually combined with other diuretics. The dose is 1 to 4 drachms (4–16 Cc.) diluted with water.

SPIRITUS LAVANDULÆ, *U. S., Br., P. G.*—Spirit of Lavender.

Alcoolat (Esprit, Eau) de Lavande, Fr.; *Lavendelspiritus*, G.

Preparation.—Oil of lavender-flowers, 50 Cc.; alcohol, 950 Cc. to make 1000 Cc. Mix them.—U. S.

Oil of lavender, 1 fluidounce; alcohol (90 per cent.), 9 fluidounces; dissolve.—Br.

Macerate for twenty-four hours lavender-flowers 1 part, with alcohol and water each 3 parts, and distil 4 parts.—P. G.

For use as a perfume a small quantity of oil of bergamot, tincture of musk, or tincture of ambergris is sometimes added, the addition of the tincture being made to the distilled spirit.

Uses.—Spirit of lavender is used more for its pleasant odor than for its carminative effect. It corresponds to the popular perfume, lavender water, which is employed by the laity to bathe the forehead in cases of headache and fever. It may be given internally in the dose of from ½ to 1 drachm (2–4 Cc.).

SPIRITUS MELISSÆ COMPOSITUS, *P. G.*—Compound Spirit of Balm.

Alcoolat de mélisse composé, Fr. Cod.—*Eau de mélisse des Carmes, Eau des Carmes*, Fr.; *Zusammengesetzter Melissengeist, Karmelitergeist*, G.

Preparation.—Take of balm (leaves), 14 parts; lemon peel, 12 parts; nutmeg, 6 parts; cassia bark, 3 parts; cloves, 3 parts. Reduce the drugs to a coarse powder, and add alcohol, 150 parts; water, 250 parts. Place the mixture in a still and distil 200 parts.—P. G.

The formula of the French Codex is very similar to the above, and directs for the same quantity of spirit 2 parts each of angelica and coriander in addition to the above-named drugs.

Compound spirit of balm, also known as Carmelite spirit, is a clear, colorless liquid, having an aromatic odor and taste. The specific gravity varies from 0.900 to 0.910.

Uses.—This preparation is a pleasant carminative and stimulant given in the dose of from ½ to 2 drachms (2–8 Cc.).

SPIRITUS MENTHÆ PIPERITÆ, *U. S., Br., P. G.*—Spirit of Peppermint.

Essence of peppermint, E.; *Alcoolat (Essence) de menthe poivrée*, Fr.; *Englische Pfefferminzessenz*, G.

Preparation.—Oil of peppermint, 100 Cc.; peppermint, bruised, 10 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Dissolve the oil of peppermint in 900 Cc. of alcohol, add the peppermint, and allow it to macerate for 24 hours; then filter through paper, adding through the filter enough alcohol to make the spirit measure 1000 Cc.—U. S.

Oil of peppermint, 1 fluidounce; alcohol (90 per cent.), 9 fluidounces; dissolve.—Br.

The formula of the P. G. agrees with that of the U. S. P., except that the spirit is made by weight and is not colored.

Uses.—This spirit is the most convenient form for the ordinary administration of peppermint. It is given in the dose of 5 to 30 minims (0.30–2 Cc.), on sugar or in sweetened water.

SPIRITUS MENTHÆ VIRIDIS, *U. S.*—Spirit of Spearmint.

Essence of spearmint, E.

Preparation.—Oil of spearmint, 100 Cc.; spearmint, bruised, 10 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Dissolve the oil of spearmint in 900 Cc. of alcohol, add the spearmint, and allow it to macerate for 24 hours; then filter through paper, adding through the filter enough alcohol to make the spirit measure 1000 Cc.—U. S.

The analogous preparation used in France is distilled from fresh crisped mint, and that used in Germany as *Englische Krauseminzessenz* is made by dissolving 1 part of oil of crisped mint in 9 parts (by weight) of alcohol.

Uses.—The uses of this preparation are the same as of the spirit of peppermint. Its dose is somewhat larger, 20 to 40 minims (1.30–2.60 Cc.).

SPIRITUS MYRCIÆ.—Spirit of Myrcia.

Bay-rum, E.

Preparation.—Oil of myrcia, 16 Cc.; oil of orange-peel, 1 Cc.; oil of pimenta, 1 Cc.; alcohol, 1220 Cc.; water, a sufficient quantity to make 2000 Cc. Mix the oils with the alcohol, and gradually add water until the solution measures 2000 Cc. Set the mixture aside, in a well-stoppered bottle, for eight days; then filter through paper in a well-covered funnel.—U. S., 1890.

To make 1 pint of bay-rum dissolve 60 minims of oil of myrcia and 4 minims each of oil of orange-peel and oil of pimenta in 10 fluidounces of alcohol, and gradually add enough water to bring the volume of the mixture up to 16 fluidounces.

On diluting an alcoholic solution of volatile oils rapidly with water a milkiness is apt to be produced, which is subsequently not readily removed by agitation; it is therefore directed to add the water gradually, so that the appearance of a permanent milkiness may be avoided as much as possible. If after a week the spirit cannot be decanted or filtered clear, it may be treated with paper-pulp or other material (except cotton-fibres) usually used in the preparation of medicated waters.

Bay-rum is distilled in several of the West Indian islands from the fresh leaves of Myrcia acris, to which a certain proportion of the fruit is added, St. Croix rum being used for the best quality; its flavor is affected by the employment of the leaves of different varieties of the plant, or probably of different closely-allied species of myrtles. (See paper by A. H. Riise in *Amer. Jour. Phar.*, 1882, p. 278.) However, most of the bay-rum consumed in the United States is now manufactured here, a small portion being distilled from the dried leaves. The above formula furnishes a preparation of agreeable fragrance and of a pale-yellowish color or nearly colorless.

Uses.—Bay rum is used as a refreshing application for headache, and to impart its pleasant odor to many toilet preparations and "hair tonics."

SPIRITUS MYRISTICÆ, *Br.*—Spirit of Nutmeg.

Alcoolat (Esprit) de muscade, Fr.; *Muskatspiritus*, G.

Preparation.—Take of volatile oil of nutmeg, 1 fluidounce; alcohol (90 per cent.), 9 fluidounces; dissolve. If the solution be not clear, agitate with a little powdered talc, and filter.—Br.

In France this spirit is prepared by macerating for four days 500 parts of bruised nutmeg with 4000 parts (by weight) of 80 per cent. alcohol, and distilling as long as alcohol passes over.

Uses.—Spirit of nutmeg is used as a flavoring agent. Its dose is from ½ to 1 drachm (2–4 Cc.).

SPIRITUS ROSMARINI, *Br.*—Spirit of Rosemary.

Spiritus anthos.—Alcoolat (Esprit) de romarin, Fr.; *Rosmarinspiritus*, G.

Preparation.—Take of oil of rosemary, 1 fluidounce; alcohol (90 per cent.), 9 fluidounces; dissolve.—Br.

The preparation known in Europe, and formerly much employed, as *Aqua Reginæ Hungariæ* (Eau de la reine de Hongrie, Fr.), is a compound spirit of rosemary, usually containing a little lavender, sage, or other aromatic oil.

Uses.—This spirit is used as a perfume, and is frequently added to lotions and liniments.

SPIRITUS SINAPIS, *P. G.*—Spirit of Mustard.

Alcoolat de moutarde, Esprit de moutarde, Fr.; *Senfspiritus*, G.

Preparation.—Take of volatile oil of mustard, 1 part; alcohol, 49 parts. Mix.—P. G.

Spirit of mustard is a clear, colorless liquid, having a pungent odor reminding strongly of oil of mustard. Its specific gravity at 15° C. (59° F.) is from 0.833 to 0.837.

Uses.—Spirit of mustard is employed as an addition to liniments intended to produce a distinct local reddening.

SPIRITUS VINI GALLICI, *U. S., Br.*—Brandy.

Spirit of French wine, E.; *Eau de vie, Cognac*, Fr.; *Franzbranntwein*, G.

An alcoholic liquid obtained by the distillation of the fermented unmodified juice of fresh grapes.—U. S.

A spirituous liquid distilled from wine and matured by age, and containing not less than 36½ per cent. by weight or 43½ per cent. by volume of ethyl hydroxide.—Br.

Origin and Preparation.—Brandy is made in France by distilling different kinds of wine. The colorless spirit (white brandy) thus obtained is kept for some time in new oak casks, where it gradually acquires a light-amber tint (pale brandy). The darker-colored varieties have their color deepened by the addition of caramel. The brandies obtained in different districts of France are not esteemed alike, those of Cognac and Armagnac being deemed the best, owing to the agreeable mildness of their flavor; next in order are those from Bordeaux and Rochelle. The lees of wines and the marc of grapes are also distilled, and furnish a spirituous liquid called in France *eau de vie de marc*, which is highly charged with odorous principles, and is used as an addition to other brandies and for imitating brandy by mixing the liquid with pure rectified spirit. The odorous constituents separated from all or most of the alcohol are sometimes met with in commerce as oil of grapes. Large quantities of brandy are also distilled in Spain and Portugal, and of recent years in Germany.

Considerable brandy is now made in the United States, and is usually distinguished as Catawba and California brandy. Catawba brandy is made in the vine-growing districts of the Ohio and Mississippi Valley, according to E. S. Wayne (1855), from the lees and from the marc. That made from the lees is the best, and has the flavor of Catawba wine. When distilled from the marc it has an unpleasant taste, and contains a large amount of fusel oil, but is mellowed down by age. California brandy is made from the lees and

marc, which are thrown together with poor wines and distilled, the distillate being tinged by the addition of caramel (*Proc. Amer. Phar. Assoc.*, 1866, p. 64).

Properties.—Brandy is a spirituous, amber-colored liquid having a peculiar flavor, which is improved by age; hence the U. S. P. directs it to be used only when at least four years old. The flavor depends upon the variety of grapes used, upon their ripeness, upon the care bestowed upon fermentation and distillation, and upon the age of the wine, an older wine yielding a more fragrant distillate. The specific gravity of brandy is required to be between .925 and .941 (U. S.), corresponding, approximately, to an alcoholic strength of 39 to 47 per cent. by weight, or 46 to 55 per cent. by volume, of absolute alcohol. It has a slight acid reaction, which is, at least in part, due to the presence of acetic acid. The odor is due to minute quantities of œnanthic, acetic, and perhaps propylic and allied ethers; its quality is best ascertained by pouring some of the brandy into a wine-glass, then emptying the latter, and, without washing or wiping it, setting it aside; the peculiar fragrance becomes then more apparent, and is still noticable after a day, while the odor of brandy which had been diluted with deodorized spirit becomes weak and disappears in the course of a few hours, during which time also the odor of whisky or similar spirits becomes apparent. Brandy assumes a dark-greenish color on the addition of ferric chloride, owing to the presence of tannin derived from the casks or from catechu, etc., purposely added. Sugar can usually be detected in the extract by Trommer's test, and is derived from caramel.

Tests.—The addition of grains of paradise, Cayenne pepper, and similar substances, sometimes used for imparting artificial strength to brandy, is detected by the sharp or burning taste of the extract left on evaporation. With sufficient practical experience the origin of brandy may be recognized by Molnar's method (see SPIRITUS FRUMENTI), but it is more difficult to distinguish by their odors the ethers and fusel oils of the French wines used for making brandy than the fusel oils of different kinds of grain. "If 100 Cc. of brandy be very slowly evaporated in a weighed capsule on a water-bath, the last portion volatilized should have an agreeable odor, free from harshness (absence of fusel oil from grain or potato spirit). The residue, dried at 100° C. (212° F.), should weigh not more than 0.25 Gm. This residue should have no sweet or distinctly spicy taste (absence of added sugar, glycerin, or spices). It should nearly all dissolve in 10 Cc. of cold water, forming a solution which is colored not deeper than light-green by a few drops of ferric chloride test-solution diluted with 10 volumes of water (absence of more than traces of oak tannin from casks). 100 Cc, of brandy should be rendered distinctly alkaline to litmus by 1 Cc. of the normal volumetric solution of potassium hydroxide (limit of free acid). If 50 Cc. of brandy be shaken vigorously in a stoppered flask with 25 Gm. of kaolin, and, after standing ½ an hour, be filtered, the color of the filtrate should not be lighter than that of the brandy before treatment (absence of caramel coloring."—U. S.

Uses.—Brandy when pure and of at least 4 years of age is perhaps the most agreeable form in which to administer alcohol to fever patients. The difficulty in obtaining an unadulterated article has caused it to be largely replaced by whisky. A few drops of brandy on cracked ice will frequently allay nausea after other remedies have failed.

SPONGIÆ.—Sponges.

Éponges, Fr.; *Schwämme, Badeschwämme*, G.; *Esponjas*, Sp.

Spongia officinalis L. (Ord. *Ceratospongiæ*).

Origin and Description.—Although sponges have for many years been recognized by naturalists as animals, they are still regarded by some persons as plants. They belong to the order of metazoa, characterized by multitudes of cells, each performing its own part in the economy of the individual, and while reproduction by division is frequent in certain groups, all have recourse to specialized cells or eggs for the perpetuation of the species.

Sponges are aquatic, are found in the water of every part of the globe, and may be exceedingly abundant in suitable locations. So far as known they are all sedentary animals, compelled, with few exceptions, to pass all but the earliest stages of existence fastened to the same submerged object to which they became attached in their early youth. The young possess powers of locomotion, and can seek out new places of abode, but the adults must remain in one place and take whatever of food and fortune the

passing currents may bring them. Thus they can only live and flourish where there are floating clouds of microscopical plants and animals and their spores. These form their staples of subsistence, and must come to them as the rain comes to the plant. In their natural state, sponges somewhat resemble in appearance a jelly-fish or a mass of liver, the entire surface being covered with a thin, slimy skin, usually of a dark color, and perforated to correspond with the apertures of the canals, commonly called "holes of the sponge."

Commercial sponge is, in reality, only the skeleton of the animal. The composition of this skeleton varies in the different kinds of sponges, but in the commercial grades it consists of interwoven horny fibres, among and supporting which are spiculæ of silicious matter in greater or less numbers, and having a variety of forms. The fibres consists of a network of fibrils, whose softness and elasticity determines the commercial quality of a given sponge. The horny framework is perforated externally by very minute pores and by a less number of larger openings. These are parts of an interesting double, external and internal, canal system. At the smaller openings on the sponge's surface channels begin, which lead into dilated spaces. In these, in turn, channels arise, which eventually terminate in the large openings. Through these channels or canals definite currents are constantly maintained, which are essential to the existence of the sponge. The currents enter through the small apertures and emerge through the large ones.

The active part of the sponge—that is, the part concerned in nutrition and growth—is a soft, fleshy mass partly filling the meshes and lining the canals. It consists largely of cells having different functions; some utilized in the formation of the framework, some in digestion, and others in reproduction. Lining the dilated spaces into which afferent canals lead are cells surmounted by whip-like processes. The motion of these processes produces and maintains the water currents, which carry the minute food products to the digestive cells in the same cavities. Sponges multiply by the union of sexual products. Certain cells of the fleshy pulp assume the character of ova, and others that of spermatozoa. Fertilization takes place within the sponge. The fertilized eggs, which are called larvæ, pass out into the currents of the water, and in the course of 24 to 48 hours they settle and become attached to rocks and other hard substances, and in time develop into mature sponges. The depth of the water in which sponge grows varies from 10 to 50 feet in Florida, but considerably more in the Mediterranean Sea, the finer grades being found in the deepest water, having a surface temperature of 50° to 57° F. in winter.

The method of obtaining sponges in the Mediterranean is by means of divers, with and without apparatus, although the use of apparatus was prohibited by the Turkish Government many years ago, owing to the excessive fishing, thus deteriorating the sponge beds, which require about three years to properly develop. As a consequence these goods became scarce and greatly enhanced in value. A diver usually stays below the water ½ to 1 minute, gathering what he can in the meantime, though, with apparatus, he can remain below the surface considerably longer. His work is very hard, owing to the pressure of the water. He is trained to his work when very young, and seldom lives more than thirty years. In the Florida and West Indian waters the fishing is done in flat-bottom boats, called dinghys. A special apparatus, known as a sponge glass, is used to help locate the sponges. It is made from an ordinary wooden bucket, the wooden bottom being replaced by one of ordinary window glass, securely fastened by cement. In using a sponge glass, it is placed upright on the surface of the water; the handle of the bucket is placed on the back of the neck of the fisherman, with his head thrust down in the bucket. In this way the fisherman can distinctly see very small objects in very deep water, and he can even distinguish good sponges from those of an inferior grade. When suitable sponges are located, they are brought up by means of a long pole, about 30 feet in length, with a sharp curved double hook, and placed in the boat. The sponge hooks are made of iron with 3 curved prongs, measuring about 5 or 6 inches in width. The entire length of the hook is about 8 inches, the upper end being made into a very strong socket for the insertion of the pole. As soon as the fisherman collects a sufficient quantity of sponges, he takes them to the vessel, where they are spread carefully on the deck, in their natural upright position, so as to allow the slimy matter, called "gurry" by the fisherman, to run off easily. During the first stages of decomposition they have a very unpleasant odor, something like decayed fishy matter. After the dinghys collect sufficient sponges to make a vessel load, they are

taken to what is called a sponge kraal, which is an enclosure of about 10 to 12 feet, made generally by placing stakes in the beach where the water is from 2 to 3 feet deep.

Sponges, after being kept on the decks of the vessel from 1 to 2 days, will generally be sufficiently cured to be taken to the kraals, where they are kept for a few days, and then thoroughly washed and pounded with a flat stick. They are then placed upon strings of about 6 feet in length and taken to the markets, where they are sold at auction. They are generally sold in lots, and then carefully trimmed and packed in bales weighing from 15 to 100 pounds each, according to quality, the cheaper grades being generally packed in the larger bales.

Varieties of Sponge.—In commerce there are found many different varieties of sponges, namely: Sheepwool, Velvet, Yellow Grass, Glove, Reed, Hardhead, and Wire, emanating from Florida and the West Indies, each variety having several different grades. The Mediterranean gives us "Honeycomb" sponges, commonly called "Mediterranean Bath" or "Turkish Bath," "Silk or Surgeon" sponges, "Elephant's Ear" or "Washrag" sponges, there also being several different grades of each variety. Varieties of Sheepwool are named Rock Island, Key, and Matacomby, obtained from Florida; Abaco, Cuba, and Nassau from the West Indies, their names being given in order as to quality, the most valuable being Rock Islands, which are of a strong fibre and best form, being most valuable for carriage washing and heavy work. This grade also makes fine bath sponges, when bleached, after having been treated with diluted hydrochloric acid to dissolve out calcareous matter, with potassium permanganate and oxalic acid, which gives them a white color, and then washed in a bath of sal-soda, thus neutralizing the acid and changing the color to yellow or lemon. This method, however, greatly weakens the fibre of the sponge, thus ruining it as regards durability. A better method, though not so pleasing to the eye, is to wash the natural sponge in a weak solution of oil of vitriol, say 1 part to 20 of water, allowing them to remain in until the dark color is taken out of the sponge, then thoroughly washing in water. This process does not injure the sponge, makes it look cleaner, and removes all calcareous matter contained therein.

Key Sheepwool is of good form, soft, and close fibre, lacking strength owing to the iron in the sponge, which is signified by a bright red color at the root and running entirely through the structure of the sponge. It is extensively bleached and looks nice, but wears badly, owing to the excessive use of acids, necessary to extract the iron from the sponge.

Abaco Sheepwool resembles the Rock Island, though lacking its strength.

The Cuba Sheepwool somewhat resembles the Key variety, and is used for carriage purposes.

The Nassau, being the coarsest grade, and irregular as regards the horny fibre and firmness, also shape, is the cheapest grade of Sheepwool Carriage Sponges.

The Velvet Sponges, of which there are several varieties (*i. e.*, Abaco, Cuba, and Cay, from the West Indies, also a hard variety from Florida), are much used as cheap carriage sponges and for general purposes, being moderate in price. The Abaco and Cuba Velvet are the best and much resemble Sheepwool. A large hole at the top of this sponge spoils its utility. The Cay variety is the one largely used, being more abundant. The Florida Velvet is coarse and hard, and is not generally liked, except for certain manufacturing purposes. Owing to a hole in the top of this grade of sponge, many people prefer the Coupe-sponges (*i. e.*, the large sponges cut up and trimmed), thus obtaining a nice solid sponge minus the holes. The Yellow Sponge has also several varieties: Nassau and the West Indies, Key and Matacomby from Florida. They have a good shape, but are rather brittle, and used chiefly among painters and bricklayers, and for household purposes. The best of these are the Matacomby and Key. There is also a species of Yellow Sponge, called "Hard Head," and this is what its name implies, a hard sponge. One variety, however, from Cuba, is of fine texture and soft, though somewhat weak, and is bleached, to take the place of a Surgeon Sponge.

The Grass Sponge is a very poor specie and is very low in price. It is chiefly used for manufacturing purposes, by painters, stone-masons, bricklayers, etc. The best quality and nicest shapes are bleached and sold on the market for a cheap bath sponge, and look as good in appearance as the higher grades, but give no satisfaction in wear.

The Reef Sponges, usually called "Slate Sponges," are fine in texture, but lack

strength, are extensively bleached for toilet purposes and used by manufacturers, engravers, and in surgery.

Sponges from the Mediterranean Sea are superior in quality to those from either Florida or West Indies. The horny fibres are far less pronounced, and they do not develop to the same thickness. They are finer in texture, more pliable, and grow in deep water, having a surface temperature of 50° to 70° F. in winter, which is clearer and more free from impurities, and the more difficult to obtain. The various grades are called White Turkey—*i. e.*, Silk Surgeon Sponges; Brown Turkey—*i. e.*, Zimocha, being similar, only coarser and darker in color, than the White Turkey; Leather Sponges—*i. e.*, Washrag or Elephant's Ear; Honeycomb Sponges, all of which have several different varieties. The best varieties are Mandruka Turkish Cup, deriving their name from their formation, similar to a cup; Turkey Solids, which are the same variety, only solid, as the name implies. The Leather Sponges are thin, flat, and fine in texture, used formerly in surgical intestinal work, but now chiefly for manufacturing purposes, and used considerably in Europe by veterinary surgeons. Brown Turkey—*i. e.*, Zimocha Sponges—are similar in texture to a Silk Sponge, but brittle. It is chiefly used in Europe for a horse sponge, and also for manufacturing purposes. Honeycomb Sponges are various in quality, those being known as Mandruka are found in deep water, have perfect forms and a close fibre, with no horny fibres protruding from the surface, and are specially known for their small root. This latter fact should be borne in mind in selling sponges. Many people object to large holes in the sponge, whereas the root is the chief factor in determining its strength. The "catch" of this grade is diminishing yearly, thereby enhancing their value; consequently only a few dealers import them. In commerce the "Mandruka" is a comparatively recent variety.

Next in quality comes the Bengaza, a sponge similar to the Mandruka, though somewhat coarser, but of nice shape and strong, and usually sold as a "Mandruka." This sponge grows in deep water. The cheaper varieties of Honeycomb—*i. e.*, Turkish Bath—are found in shallow water and are numerous in variety, quality varying according to depth at which they are found. They are chiefly bleached, only the finest selected being used in their natural color.

The question of propagating sponges has been discussed both as regards Florida and Mediterranean sponges, and the idea is believed to be feasible. The method is as follows: Sponges cut into small pieces will live and grow if properly attached in suitable water (clear and free from impurities). They can be cut on a moistened board with a knife or fine saw. Care must be taken not to express the soft matter. The preferred size of the cutting is about 1 inch broad and similar in height. The outer skin should be retained as far as practicable. In cutting, the lines of the circulating canals should probably be considered, although pieces cut without any reference to the directions of the canals have lived and grown. Exposure is not injurious, unless exposed too long or in very warm weather. The clippings must then be made fast, care being taken to use material that is not injurious to the sponge, and will not distort its growth. They must be fastened on the bottom in an upright position that can be maintained and not smothered by mud, sand, or sediment. The use of bamboo pegs seem to have given much satisfaction and good results attained in as short a time as a year.

Owing to the great advance in the cost of sponges during the last few years, due to the scarcity and the results of over-fishing and increased demand, of which the European market has been a factor, the packers in Florida have resorted to loading sponges that are sold by weight, to keep down the price, so as to appear to continue asking the former prices, whereas in reality the cost is 20 to 25 per cent. higher. There are several methods of accomplishing this, such as injecting in the sponge sand or marble dust, also by washing the sponges in a salt solution, and by injecting glucose and heavy syrups. To compare the difference between a pure and loaded sponge take a 2-ounce sponge of each grade, wetting them both, and it will be found that the pure article will measure about 19 inches in circumference, or thereabouts. The loaded article in comparison will only measure about 16 inches in circumference and less. Of course, this will largely depend upon the amount of foreign matter contained therein, the average herein given being taken from a bale of each kind and measured. Take a sponge of equal weight, say 2 ounces, costing $4 a pound, and pure, and a loaded sponge at $3 per pound, and it will be seen that by washing them out you are getting a larger sponge in the 2-ounce pure than in the 2-ounce loaded, and therefore the cost is practically equal,

despite the fact of there being $1 difference per pound in the price. A bale of pure sponges averaging 8 to the pound at $4 per pound will be as large, if not larger, than a loaded bale about 6 to the pound at $3 per pound. The cost of these per sponge is 50 cents. The purchasing of loaded sponges should therefore be avoided, it being illustrated that as good value, if not better, can be obtained by paying the higher price.

Many dealers are now offering Sheepwool sponges by the piece, a stated number of sponges being packed in a bale, and this method is commended, saving the retailer the trouble of figuring the individual cost of each sponge, and sometimes unconsciously losing their profits by not taking into consideration the difference of gross weight at which the sponges are usually purchased, and the net weight, and even a possible loss from the sponges drying out. In this connection we would say that sponges in bales absorb humidity in the summer time and are usually more or less damp, whereas in the winter time they lose in weight, owing to the dryness of the air.

(The above is largely from an article by Albert Hart in the *Amer. Journ. Pharm.* for 1901.)

Composition.—The organic matter of sponge is a proteid called *spongin*, which was formerly supposed to be closely allied to, or identical with, *fibroin* or *sericin* of silk, but was proved by Schlossberger (1858) and Staedeler (1859) to be entirely distinct, in being insoluble or very slowly soluble in ammoniacal solutions of the oxides of nickel and copper, and in the behavior to hot diluted sulphuric acid, with which it yields *leucin* and *glycocoll*, while sericin yields by this treatment tyrosin and serin, and is readily dissolved by solutions of nickel and copper in ammonia. Spongin is soluble in hot solution of caustic potassa and in hot mineral acids.

Action and Uses.—Before the discovery of iodine, roasted or so-called "burnt" sponge was generally used in the treatment of *goitre*, both internally and externally, and certainly with excellent results in appropriate cases; but it is now wholly superseded by the preparations of iodine. Sponge is familiarly employed for countless domestic purposes which require the use of a porous, compressible, and elastic substance capable of holding liquids, and, among others, for partial or general baths, which are of great hygienic importance. Its use in medicine and surgery for absorbing blood, pus, and other animal liquids was at one time common, but aseptic surgery now considers its employment an unmitigated evil.

Derivatives and Allied Product.—*Spongia usta*, Fr. Cod.; *Burnt sponge*, E.; *Éponge torrifiée*, Fr.—Heat clean sponge, cut into small pieces, in a coffee-roaster until about ¼ its weight has been given off. The residue consists mainly of charcoal, with 25 to 30 per cent. of calcium sulphate, 10 per cent. of silica, 9 per cent. of ferrous oxide, the remainder being magnesium carbonate, potassium chloride, and calcium phosphate, and about ½ to 1 per cent. of sodium iodide (Herberger). Some irregular practitioners use burnt sponge in the treatment of spasmodic croup. It has little if any value.

Spongia Cerata.—*Sponge tent*, E; *Éponge préparée à la cire*, Fr.; *Wachsschwämme*, G.—Sponge is freed from foreign matters by beating and washing, then dried, cut into proper shape, dipped into yellow melted wax, pressed between hot iron plates, and when cold freed from the excess of wax.

Spongia Compressa.—*Compressed sponge*, E.; *Funiculo pressa*, F. Cod.; *Éponge préparée à la ficelle*, Fr. Cod.; *Pressschwamm*, G.; *Esponja preparada*, Sp.—Perfectly clean, fine sponge is cut into elongated pieces while moist, securely tied by means of twine into cylindrical pieces, and then dried.

Vegetable Sponge or Gourd Towel.—The fibrous network of the fruit of Luffa ægyptiaca, *Miller* (Momordica Luffa, *Linné*, Fam. *Cucurbitaceæ*), has been used to some extent, under these and similar names, like a sponge and flesh-brush. Luffa petola, *Seringe*, and L. fœtida, *Cavanilles*, yield similar products. The fleshy portion of these fruits is edible, though not very palatable; several other species are violently purgative and emetic.

STANNUM.—Tin.

Etain, Fr.; *Zinn*, G.

Symbol, Sn. Atomicity bivalent and quadrivalent. Atomic weight, 118.1.

Tin is rarely found in the metallic state. Its most important ore is a binoxide, SnO_2, known as *tinstone*, which is usually imbedded in granite, quartz, or slate, and often associated with iron pyrites, and with tungstate of iron and manganese, known as the mineral *wolfram*. It is rarely met with as silicate, and is present in *columbite*, *tan-*

talite, and allied minerals, and in minute proportions in the mineral waters of Saidschütz and other places. The most important tin-mines are in Devonshire and Cornwall in Great Britain, and in Malacca and Banca, but tin is likewise obtained in Australia, Bohemia, Saxony, and some parts of the United States. Australian tin sometimes contains gold. The tinstone is stamped into a coarse powder, freed from lighter minerals by washing with a stream of water, roasted to expel arsenic and sulphur, again washed with water, mixed with powdered coal and a little lime or fluor-spar for the purpose of forming a fusible slag, and then reduced on the hearth of a reverberatory furnace.

Tin is a bluish-white metal of the specific gravity 7.3, softer than gold, but harder than lead, and when bent emitting a crackling sound. It may be rolled or hammered into *foil*, at 100° C. (212° F.), drawn into wire, and at 200° C. (392° F.) is so brittle that it may be readily reduced to powder. It melts near 230° C. (446° F.), and, according to Nies and Winkelmann (1882), on congealing increases in volume 0.7 per cent. While cooling it is readily converted into powder by trituration in a hot iron mortar; after sifting it constitutes *Stanni pulvis*, which was formerly employed. It is but superficially oxidized in moist air, and will effectually protect iron from rusting as long as the coating is perfect. Its alloy with lead forms *pewter*, *Britannia metal*, and *solder;* alloyed with copper it constitutes *gun-metal* and *bronze;* and by combining 4 parts of tin with 3 of cadmium, 8 of lead, and 15 of bismuth a fusible alloy is obtained, melting at 60° C. (140° F.).

Tin forms two series of compounds, the *stannous* and the *stannic*, in which it is bivalent and tetravalent respectively. These may be considered as being derived from stannous oxide, SnO, and stannic oxide, SnO_2. Tin, like aluminum and zinc, has both acidic and basic properties, for the oxides or hydroxides with acids give salts, and with strong alkalies they give stannites and stannates. Stannous salts are easily oxidized to stannic salts, and stannites easily pass to the stannates. There are two forms of stannic hydroxide, known as stannic acid, H_2SnO_3, and metastannic acid, $H_2Sn_5O_{11}$. The former is obtained by precipitation of stannous salts with caustic alkali, the latter by the action of concentrated nitric acid on tin. Stannic acid is soluble in acids and alkalies, while metastannic acid is not soluble in acids, but may be dissolved in hot alkalies, giving, for example, sodium metastannate, $Na_2S_5O_{11}$.

Metallic tin dissolves in hot, strong sulphuric acid to stannic sulphate, evolving sulphur dioxide. Strong hydrochloric acid dissolves it to stannous chloride, and nitro-muriatic acid yields with it stannic chloride. *Stannous salts* are precipitated brown by hydrogen sulphide, the precipitate being soluble in ammonium sulphide. Gold chloride produces a deep-purple precipitate (*purple of Cassius*), and mercuric chloride is reduced either to calomel or to a gray powder of metallic mercury. This reaction explains the value of stannous chloride as a test for salts of mercury. *Stannic salts*, of which the chloride, $SnCl_4$, is used by dyers, do not react with the chlorides of gold and mercury, but yield with hydrogen sulphide a yellow precipitate which is soluble in ammonium sulphide. Both stannous and stannic salts are precipitated white by potassium hydroxide; the precipitates are soluble in an excess of the reagent, and the alkaline solution, when obtained from stannous salts, yields on boiling a black precipitate of stannous oxide. Of the sulphides, *stannic sulphide*, SnS_2, is of interest; it is made by heating a mixture of tin amalgam, sulphur, and sal ammoniac, when it remains behind in golden-yellow scales, ammonium chloride and sulphide and chloride of mercury subliming; when ground, stannic sulphide is known as *mosaic gold* and *bronze powder*.

Sodii Stannas, *Natrium stannicum, Sodium stannate.—Preparing salt.* $Na_2SnO_3.3H_2O$. This is used by calico printers as a mordant, and is prepared on the large scale by fusing tin ore with soda and sodium nitrate or by boiling it with strong caustic soda. The salt forms pearly crystals and comes into the market mostly as colorless masses. It is easily soluble in water, and is decomposed by acids, even carbonic, as well as by boiling with ammonium chloride, with precipitation of stannic acid. This behavior is utilized to precipitate the acid on fibres in the dyeing industry, which then have the power of combining with color bodies. This process is known as mordanting.

Action and Uses.—Neither tin nor its salts are employed in modern medicine. Tin in filings and powder was formerly recommended and used as a tæniacide, the destruction of the worm being due to the mechanical action of the foreign substance. From 1 to 4 drachms (4–16 Gm.) were administered, suspended in syrup or made into an electuary, and followed in from 3 to 6 hours by a brisk cathartic. Some of the salts of tin, chiefly

the chloride, are credited with vermicidal properties. The effect of poisonous quantities of tin upon the organism is said to be similar to that of lead. In the dose of $\frac{1}{16}$ to $\frac{1}{2}$ grain (0.004–0.03 Gm.) chloride of tin has been employed as an antispasmodic in chorea, epilepsy, and other convulsive diseases. Externally it is astringent and irritant, and has been applied to slowly healing ulcers.

SALTS OF TIN.

Stanni Chloridum.—*Stannous chloride*, E.; *Stannochlorid, Zinnchlorür*, G. Tin salt. $SnCl_2.2H_2O$. This is formed by dissolving tin in strong hydrochloric acid and crystallizing from acid solution. It is known commercially as *tin salt*, and is used extensively as a mordant. It is soluble in acidified water or alcohol. Much water decomposes it into basic chloride, Sn(OH)Cl. Air oxidizes it to stannic oxychloride, $SnOCl_2$, and stannic chloride, $SnCl_4$.

Bettendorf's Reagent.—This is a saturated solution of stannous chloride in strong hydrochloric acid, used in testing for arsenic. The reactions are $As_2O_3 + 3SnCl_2 + 6HCl = As_2 + 3SnCl_4 + 3H_2O$, and $As_2O_5 + 5SnCl_2 + 10HCl = As_2 + 5SnCl_4 + 5H_2O$.

Stannic Chloride. $SnCl_4.5H_2O$.—This is formed when tin is dissolved in aqua regia, or by passing chlorine into a solution of stannous chloride. It is used in the dyeing industries. When tin is treated with chlorine, anhydrous stannic chloride is formed, a colorless fuming liquid, boiling at 114° C. (237.2° F.), and long known as *spiritus fumans Libavii*. A solution of the chloride, when boiled, yields stannic and hydrochloric acids. Stannic chloride forms combinations with other chlorides, such as $SnCl_4.2NH_4Cl$, which is known in commerce as *pink salt*, and is used in cotton-printing. $SnCl_4.2NaCl.5H_2O$ is the so-called *crystallized tin chloride*.

STAPHISAGRIA, *U. S.*—Staphisagria; Stavesacre.

Staphisagriæ semina, Br.; *Semen staphisagriæ, staphidis agriæ*, or *pedicularis*.—*Stephanskörner, Läusekörner*, G.; *Staphisagrie*, Fr.; *Astaphysagria, Paparraz*, Port.; *Estafisagria, Albarraz*, Sp.

The dried ripe seed of *Delphinium Staphisagria* L. (Fam. *Ranunculaceæ*).

Staphisagria is official in most European pharmacopœias.

Origin.—The plant yielding these seeds is a tall, stout, hairy biennial larkspur, native of southern Europe and adjacent Asia, and somewhat cultivated for its seeds. Holmes has shown that the species formerly grown in gardens, and figured under this name, is distinct.

FIG. 409.

Stavesacre seeds (× 2).

Description.—About 5 to 7 Mm. ($\frac{1}{5}$–$\frac{1}{4}$ In.) long and nearly as broad, flattish-tetrahedral, one side convex, another small and opposite to a pointed extremity, the edges rather acute; brown, gray brown or sometimes blackish, strongly and coarsely reticulate-wrinkled, containing a whitish, or becoming gray brown, oily perisperm and a small, straight embryo; nearly inodorous, taste very bitter, acrid, and somewhat biting. The yield of ash is from 3 to 4 per cent.

The seed of *Delphinium Consolida* L., of similar shape and structure, but several times smaller, black, and with sharper angles and ridges, may be substituted for external use.

Constituents.—Staphisagria contains, besides about 25 to 30 per cent. of a non-drying fixed oil, a little volatile oil, several resins, and unimportant substances, a total of about 1 per cent. of three, or possibly more, alkaloids, to which its properties are due. Most of the alkaloidal matter is retained in the fixed oil when the latter is extracted by solvents, so that this has been used for the same purposes as the seeds. The most important alkaloid is *delphinine* ($C_{31}H_{49}NO_7$), of which Katz obtained 30 grammes from 50 kilos of seeds by the following method: The seeds were extracted by ether, the solution precipitated by ethereal solution of oxalic acid and by shaking out with tartaric acid, precipitating the acid solution with sodium cyanide, shaking out the remaining liquid with ammonia and ether, evaporating the ether, and recrystallizing from alcohol, when the delphinine was obtained in shining colorless crystals. The portion remaining in the cyanide precipitate was then recovered by the use of acetone. Delphinine is soluble in alcohol, ether, and chloroform, melts at 191° C. (375.8° F.). Its double platinum salt is soluble in water, as well as in alcohol and chloroform, crystallizing from the last in acicular yellow crystals. *Delphisine* he regards as a decomposition-product of delphinine. It occurs in needles and contains one more atom of hydrogen, and Katz converted

it into delphinine by simple recrystallization. Delphinine acts much like aconitine. *Delphinoidine* ($C_{25}H_{42}NO_4$), accepted by most authors, not biting and then numbing, and more narcotic than delphinine, Katz regards as a decomposition-product. Other alkaloids which have been reported are *staphisagrine*, now generally regarded as a mixture, *staphisagroine* (Ahrens), which Katz regards as the only naturally existing alkaloid other than delphinine, and *calcitrapine*, of which nothing definite is known.

Pharmaceutical Preparation.—Fluidextract of Staphisagria, U. S. P.

Action and Uses.—Staphisagria is employed in medicine solely as a local application for the destruction of lice and the itch-mite. For this purpose it may be applied in ointment or in a lotion composed of equal parts of the fluidextract and ether. Applied to an abraded surface, it will cause much irritation. Internally it is decidedly irritant to the gastro-intestinal mucous membrane, and its administration in full doses results in violent vomiting and purging. Delphinine has been used with reputed success in the local treatment of neuralgia by applying it in ointment (10 to 40 grains (0.60–2.60 Gm.) to the ounce [30 Gm.]) over the painful nerve.

Other Species.—*Delphinium*, or *Larkspur* (*Staggerweed*, *King's Consonud*, E.; *Ritter-sporn*, *Lerchenklaue*, *Hornkümmel*, G.; *Pied d' alouetta*, Fr.), the dried ripe seeds of *D. Consolida* L., of central Europe, referred to under *Description*, are used in precisely the same way as staphisagria, and the constituents are doubtless nearly or quite identical. Those of at least a dozen other species are similarly used.

The genus *Delphinium* L. comprises some 120 species, nearly half of them in North America. They are generally poisonous, in the same way as staphisagria, in all their parts, and some of them are among the most serious stock-poisons in grazing regions. *D. brunonianum* Royle is the Indian *Samp-phali*.

STILLINGIA, *U. S.*—Stillingia.

Queen's root or *delight*, *Silver-leaf*, *Yaw-root*, E.; *Stillingie*, G., Fr.

The dried root of *Stillingia sylvatica* L. (*Sapium s.*—Torr.—Fam. *Euphorbiaceæ*).

Stillingia is not official in any other pharmacopœia.

Origin.—The Stillingia plant is a stout, perennial, milky-juiced herb, from 1 to 3 ft. high, inhabiting sandy soil, in exposed locations, throughout the southeastern United States, from Virginia to Texas. The habit of the plant and the appearance of the root are here illustrated. The upper flowers are staminate, diandrous, the lower are pistillate, 3-carpelled. The root is collected in late autumn or early spring.

Fig. 410.

Stillingia: plant and root (½ Nat.); section (Nat.).

Description.—Occurring usually in short transverse sections of very long tapering, slenderly fusiform roots, about 2.5 Cm. (1 In.) or less in thickness, very light, tough and spongy; externally of a deep, or occasionally a light reddish brown, finely, shortly, and crookedly longitudinally wrinkled and incompletely annulate, especially the thicker portions, with constrictions, which frequently become slight fissures; ends of the sections pinkish, very fuzzy with innumerable partly detached fine bast-fibres, the bark very thick, containing scattered fine resin-cells and lactiferous ducts, the wood radiate, fibrous, and porous; odor slight, peculiar; taste pungent, bitter, and acrid.

Constituents.—The activity of stillingia, except for its 10 or 12 per cent. of tannin, is due to 3 or 4 per cent. of a volatile oil, a fixed oil, and a resin which has been called *sylvacrol*. The volatile oil is strongly and unpleasantly odorous. The fixed oil,

which is ether-soluble, shares the acridity of the sylvacrol, which latter can be extracted by alcohol or chloroform. A little gum is associated with the resin. Starch is present in moderate amount, and the ash should not exceed 5 per cent.

Pharmaceutical Preparation.—Fluidextract of Stillingia, U. S. P.

Action and Uses.—Stillingia belongs to that class of drugs to which powerful alterative properties were attributed, but, like the other members of the group, the evidences of its power are not very convincing. It has been used, especially in the Southern States, as a remedy in syphilis, scrofula, sluggish cutaneous diseases, and chronic hepatic affections. In large does it is emetic. It is administered in the dose of ½ to 1 drachm (2–4 Cc.), in decoction or fluidextract.

STRAMONIUM, *U. S.*—Stramonium Leaves.

Thorn-, *Devil's-*, or *Mad-apple*, *Apple of Peru*, *Stink-weed*, *Jamestown* (Jimson) *weed* or *lily*, *Devil's trumpet*, *Derotry*, E.; *Stechapfel*, *Dornapfel*, G.; *Feuille de stramoine* or *de porume épineuse*, Fr.; *Foglie di Stramonio*, It.; *Folha de Estramonia*, *Figuiera do Inferno*, Port.; *Hoja de Estramonio*, or *de Toloache*, Sp.

The dried leaves of *Datura Stramonium* L. (*Stramonium spinosum* Lam.—Fam. *Solanaceæ*) yielding, when assayed by the U. S. P. process, not less than 0.35 per cent. of its alkaloids.

Stramonium leaves are official in all pharmacopœias. Many require that they be renewed annually. The Belgian excludes discolored leaves. The Portuguese directs the use of the entire plant except the root, and allows the substitution of *D. Tatula* D.C. (which should be L.).

Origin.—The stramonium plant, native of Asia, is naturalized in most temperate and sub-tropical countries, and is exceedingly common and abundant in the United States, in rich ground, especially about barn-yards, lumber-yards, docks, and other waste places. It is an annual, and one of our largest and coarsest herbs, reaching a height of 1 to 2 M. (3 to 6 Ft.), and its spreading branches covering an area almost as broad. The root is white, the stems and branches pale green, the leaves dark green, the flowers white. The plant is smooth, except for a slight pubescence on the younger parts, and exhales a rank, very heavy and somewhat nauseating narcotic odor. The leaves and seeds are described below, and the habit is shown in the accompanying illustration. All parts of the plant are exceedingly poisonous. We have seen the pupils widely dilated by accidentally rubbing the eyes with the fingers, after pulling the fresh leaves from a plant. Fatal cases of poisoning are of annual occurrence in and near most

Fig. 411.

Datura stramonium L.: flowering branch (⅓ Nat.).

Fig. 412.

Capsule, mature, with two valves removed, showing partitions and position of seeds (¼ Nat.).

of our large cities, and it is estimated that in India this plant causes more deaths than any other. The leaves should be gathered when the plant is in full bloom and dried carefully in the shade. To how great an extent it is true that the quality deteriorates on being kept is mostly conjectural.

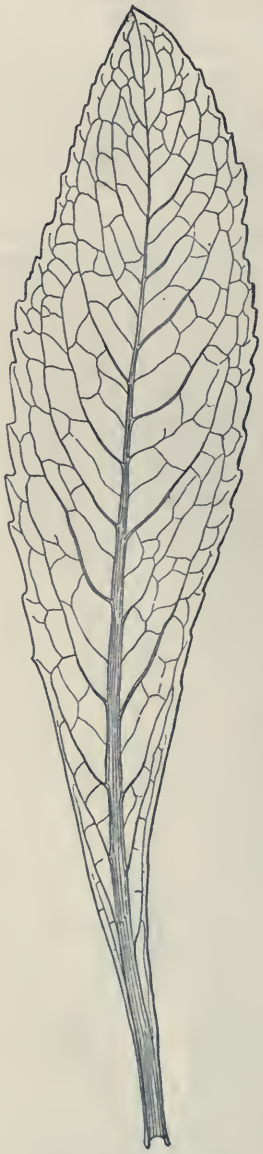
Description.—A much wrinkled, deep- or somewhat grayish-green, rarely very slightly brownish, mass, consisting of petioled leaves, the blades 12 to 25 Cm. (5–10 In.) long and

about two-thirds as broad, inequilaterally ovate, very oblique at the base, acuminate and acute at the apex, very coarsely dentate or sublobed, the large teeth few, acute, with rounded sinuses; thin, smooth, the principal veins few and coarse; odor slight, narcotic when bruised; taste bitter and disagreeable.

The powder is bright green and exhibits stout, conical hairs of 2 or 3 thick-walled cells placed end to end, their surface warty-roughened, much smaller hairs having enlarged, glandular heads of 2 to 4 cells, and numerous stellate or rosette crystals, a few prismatic. Schlotterbeck distinguishes the powders of the 3 closely related leaves, belladonna, stramonium, and hyoscyamus, by these crystals, those of belladonna being mostly in the form of fine crystal-sand or needles, those of hyoscyamus "prismatic" or in twin forms, seldom if ever stellate.

Aside from the accidental substitution of belladonna leaves, stramonium is liable to be adulterated with those of *D. Tatula* L., a species with purple stem and petioles and bluish- or violet-white flowers. The leaves are mostly smaller and have purplish petioles and midribs.

FIG. 413.



Spurious ("French cultivated") stramonium (⅔ Nat.).

In 1900 a large shipment of so-called "French cultivated stramonium" was offered in New York. One of these leaves is here illustrated.

Constituents.—Stramonium-leaves yield 17 to 20 per cent. of ash, are rich in potassium nitrate, to which, doubtless, part of their antispasmodic effects are due, and contain a trace of volatile oil, gum, and other unimportant substances, besides an amount of alkaloid which has been variously estimated at from 0.2 to 0.4 per cent. It is probable that most analyses have given too low results, owing to the large amount of chlorophyll present. Schmidt, who followed a method designed to avoid this error, reported the larger percentage stated above. As to the identity of this alkaloid, we cannot consider information at all sufficient. It was originally called "daturine," but is now known to be identical with other solanaceous alkaloids, hyoscyamine, or atropine, or a mixture of the two in undetermined, and probably very variable, proportions. It is generally regarded as being chiefly hyoscyamine. There is probably, also, a little hyoscine present. All these alkaloids are elsewhere discussed.

Assay of Stramonium.—The method to be employed is identical with that given for Belladonna Leaves, using 10 Gm. of stramonium in No. 60 powder.—U. S. (See page 286.)

Pharmaceutical Preparations.— EXTRACT OF STRAMONIUM, FLUIDEXTRACT OF STRAMONIUM, TINCTURE OF STRAMONIUM, U. S. P.

Action and Uses.—The physiological action of stramonium and its alkaloid, daturine, is almost identical to that of belladonna and atropine. Those specimens which contain a small quantity of hyoscine are slightly more sedative to the central nervous system than is belladonna. In poisonous doses they produce the same symptoms and are subject to the same treatment. (See BELLADONNA.) Stramonium was at one time esteemed as a sedative in epilepsy and in acute mania and other forms of active insanity, but experience has failed to confirm the favorable judgment. It is a useful antispasmodic in dysmenorrhœa, whooping cough, retention of urine due to spasm at the neck of the bladder. Its employment in spasmodic asthma is attended by gratifying results. It may be used by smoking the dried leaves in a pipe or cigarette, either alone or mixed with cubebs, sage, belladonna, and other drugs. The fumes emitted by burning cones made of stramonium, potassium nitrate, and some aromatic are equally efficacious. If possible the smoke should be inhaled into the lungs. Applied locally in ointment, stramonium will palliate the pain of muscular rheumatism, neuralgia, and both the pain

and tenesmus due to hemorrhoids, anal fissure, and other inflammations in the region of the anus. Daturine may be substituted for belladonna and its alkaloid as a mydriatic. Stramonium is given in substance in the dose of 1 to 3 grains (0.06–0.20 Gm.). The dose of the fluidextract is 1 to 3 minims (0.05–0.20 Cc.), of the extract $\frac{1}{8}$ to $\frac{1}{4}$ grain (0.006–0.015 Gm.), and of the tincture 10 to 30 minims (0.60–2 Cc.).

Allied Drugs.—*Stramonium seeds* (*Stramonii semina*, Br.), the dried ripe seeds of the plant discussed above are official in a number of pharmacopœias, and were so in the U. S. P. preceding the edition of 1900. They are about 3.5 Mm. ($\frac{1}{8}$ In.) long and two-thirds as broad, flattened-reniform, the hilum at one side of the concavity; testa dull black or blackish, hard, coarsely and shallowly reticulate-wrinkled, and very finely pitted; perisperm whitish, oily, concealing a cylindrical, curved embryo; odor unpleasant when bruised; taste sweetish and bitter, then somewhat acrid.

Fig. 414.

Stramonium-seed and section (× 3).

Except that they contain about 25 per cent. of fixed oil, and no chlorophyll, their constituents are practically the same as those of the leaves. They have generally been regarded as containing more alkaloid than the leaves, but it appears likely that at least the most of this difference was due to a failure of assayers to detect the full amount contained in the leaves.

The genus *Datura* L. contains from 4 to 15 species, according to whether certain groups are regarded as sub-genera or distinct genera. They are characterized by the same properties as those of the official species, and the alkaloids are doubtless nearly if not quite identical. Hyoscine has been found in the flowers of *D. fastuosa* L. (*D. alba* Nees) of the East Indies, Egypt, etc. This species probably includes the *D. Nilhumatu* Dun., which yields the Indian drug *Nila-humatu*.

STRONTII BROMIDUM, *U. S.*—Strontium Bromide.

Bromure de strontium, Fr.; *Strontiumbromid*, G.

Formula, $SrBr_2 + 6H_2O$. Molecular weight, 352.94.

It should contain not less than 97 per cent. of pure salt, and should be kept in glass-stoppered bottles.—U. S.

Preparation.—Strontium bromide is best made by neutralizing diluted hydrobromic acid with strontium carbonate (free from barium and calcium) in excess, filtering the mixture, and evaporating the clear solution until crystals begin to form. Upon cooling the salt separates in crystals, which are then carefully dried to prevent efflorescence, which takes place at elevated temperature.

Properties.—Strontium bromide occurs in colorless, transparent, hexagonal crystals, odorless, and having a bitter saline taste; they are very deliquescent, and should be kept in well-stoppered vials. The salt is soluble in 1 part of water at 25° C. (77° F.) and in 0.4 part of boiling water, the aqueous solution being neutral to litmus-paper; it is readily soluble in alcohol, and is precipitated from this solution upon the addition of an equal volume of ether, in which it is insoluble. To a non-luminous flame the salt communicates an intensely red color. When heated the crystals first melt, and at 120° C. (248° F.) lose all their water of crystallization (30.4 per cent.); the anhydrous salt fuses at 630° C. (1166° F.). With calcium sulphate the aqueous solution of the salt (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids; the same reaction occurs more quickly with diluted sulphuric acid, potassium sulphate, and other soluble sulphates. With potassium chromate it forms a yellow precipitate of strontium chromate soluble in acetic acid. With ammonium carbonate or sodium carbonate it forms a white precipitate of strontium carbonate, soluble with effervescence in acetic acid. If 1 Cc. of chloroform be added to 10 Cc. of the solution (1 in 20), then drop by drop chlorine water, which has been diluted with an equal volume of water, and the mixture shaken, the liberated bromine will dissolve in the chloroform, communicating to it a yellow or brownish-yellow color, free from any violet tint (absence of iodine).

Tests.—If 1 Gm. each of strontium bromide and sodium acetate be dissolved in 5 Cc. of distilled water, and the solution be made slightly acid through the addition of from 3 to 5 drops, or a sufficient quantity of diluted acetic acid, the solution should, upon addition of 5 drops of potassium dichromate test-solution and agitating, not become cloudy within 5 minutes (absence of barium). A 5 per cent. solution slightly acidulated with hydrochloric acid should not be affected by an equal volume of hydrogen sulphide solution, when kept corked at 35° C. (95° F.) for at least half an hour, either before or after

adding ammonia-water to slight excess (absence of heavy metals). If 0.5 Gm. of the salt be dissolved in 50 Cc. of distilled water, and a few drops of potassium chromate test-solution be added, it should require not less than 27.48 Cc. nor more than 29 Cc. of tenth-normal silver nitrate solution to produce a permanent red color (corresponding to at least 97 per cent. of pure bromide).—U. S. Each Cc. of the silver solution represents 0.017647 Gm. of pure $SrBr_2.6H_2O$, and 0.5 Gm. of the pure salt would require 28.33 Cc. for precipitation. The lower limit, 27.48 Cc., of silver consumed represents 0.4849 Gm. of the pure salt, or 96.98 (97) per cent. If chloride be present, the quantity of silver solution consumed is increased above that required for the pure salt, and each 0.095 Cc. consumed in excess of 28.33 Cc. represents 1 per cent. of strontium chloride as impurity, provided that is the only one present that acts with silver solution. The excess of (29 Cc.–28.33 Cc.) 0.67 Cc. of silver allowed by the U. S. P. represents 7.05 per cent. of chloride, which is too large. The presence of calcium would also tend to throw the titration figure above the theoretically required amount of silver solution, and it may be that the U. S. P. allows for the presence of such impurity. On the whole, the titration with silver nitrate is unreliable, as it is apt to lead to erroneous results unless care be taken to interpret the titration properly (see remarks under POTASSII BROMIDUM).

The preparation of *pure* strontium carbonate is attended with more or less difficulty, and H. B. Dunham (1893) proposes to use strontium hydroxide instead, which latter can either be dissolved in the respective acids or can be decomposed by the appropriate salts of ammonium. Strontium hydroxide $Sr(OH)_2$, strictly pure, can be rapidly prepared, according to Dunham, by heating strontium nitrate in a capsule for about twenty minutes over a direct fire, which converts it into oxide; the latter is mixed with more than sufficient water to slake it, and after subsiding the clear liquid is poured off, and the residue is again treated with water in the same manner: by this treatment all barium hydroxide is effectually removed, being soluble in 20 parts of water, whereas the strontium hydroxide requires 60 parts of cold water. To free the strontium salt from any calcium possibly present, it is now dissolved in boiling water (requiring 2.4 parts), and the solution then set aside to crystallize: the crystals occur in transparent square prisms with 8 molecules of water.

Action and Uses.—Strontium bromide is used for precisely the same conditions as the other bromides. It possesses advantages over potassium bromide in exerting a nutritive influence upon the system, and in being less apt to produce a rash or unpleasant symptom of bromism. In addition to the ordinary effects of bromides, the strontium salt is useful as a sedative in gastric indigestion of nervous origin. It is given in somewhat larger doses than the other bromides, the average daily quantity being from 1 to 3 drachms (4–12 Gm.).

STRONTII IODIDUM, *U. S.*—Strontium Iodide.

Iodure de strontium, Fr.; *Strontiumjodid*, G.

Formula, $SrI_2 + 6H_2O$. Molecular weight, 446.02.

It should contain not less than 98 per cent. of the pure salt, and should be kept in small glass-stoppered vials, carefully protected from light.—U. S. Deeply colored strontium iodide should not be dispensed, but may be deprived of free iodine by agitation with several portions of carbon disulphide or chloroform and quickly drying on bibulous paper.

Preparation.—Like other strontium salts, the iodide is no doubt best prepared by neutralizing the respective acid with strontium carbonate. Since hydriodic acid is rather unstable, a freshly prepared solution of it should be employed, the excess of strontium carbonate removed by filtration, and the clear solution concentrated by evaporation. When cold, strontium iodide will separate in crystals.

As stated under STRONTIUM BROMIDE, the iodide may also be obtained by neutralizing hydriodic acid with strontium hydroxide and evaporating the solution to the crystallizing point.

Properties.—Strontium iodide occurs in colorless, transparent, hexagonal plates, odorless and having a bitterish, saline taste. The salt is deliquescent, and easily colored yellow by exposure to the air and light. It is soluble in 0.5 part of water at 25° C. (77° F.) and in 0.27 part of boiling water; also soluble in alcohol and slightly in ether;

the aqueous solution is neutral or only very slightly acid to litmus-paper. When cautiously heated the crystals melt, and gradually lose their water of crystallization (24.05 per cent.), becoming anhydrous: at a red heat they are decomposed, losing iodine, and leaving a residue of strontium oxide.—U. S. To a non-luminous flame the salt communicates an intensely red color. If 1 Cc. of chlorine water be added to 5 Cc. of an aqueous solution of the salt, iodine will be liberated and impart to the solution a light reddish-brown color; on agitating the mixture with a few drops of chloroform this will acquire a violet color. Toward calcium or potassium sulphate, potassium chromate, and sodium or ammonium carbonate, strontium iodide behaves precisely like the bromide.

Tests.—It should not respond to the tests for barium and for heavy metals detailed under STRONTII BROMIDUM. If 0.5 Gm. of the salt be dissolved in about 100 Cc. of distilled water, contained in a flask, and 25 Cc. of tenth-normal silver nitrate solution, 5 Cc. of nitric acid, and 5 Cc. of ferric ammonium sulphate test-solution be successively added, the flask stoppered and thoroughly shaken, then it should require not less than 1.7 Cc. nor more than 3.1 Cc. of tenth-normal potassium sulphocyanate solution to produce a permanent red tint (corresponding to 98 per cent. of pure strontium iodide).—U. S. The minimum and maximum limits of silver solution allowed in the titration are 21.9 Cc. and 23.3 Cc. respectively, and the theoretical quantity required for 0.5 Gm. of pure $SrI_2.6H_2O$ is 22.42 Cc. Each Cc. of silver solution represents 0.0223 Gm. of the pure salt, hence the lower limit, 21.9 Cc., corresponds to 0.4884 Gm. of pure iodide in 0.5 Gm. assayed, or 97.68 per cent. The upper limit of silver solution, 23.3 Cc., is (23.3–22.42) 0.88 Cc. in excess of the theoretical quantity, which may be due to the presence of strontium chloride as impurity. Each 0.154 Cc. of silver solution in excess represents 1 per cent. of chloride, provided that is the only impurity reacting with the silver solution, and 0.88 Cc. excess represents 5.7 per cent., which is much larger than the Pharmacopœia allows. As in the case of strontium bromide, the excess of silver solution allowed may be partly attributable to the presence of calcium salt as impurity. It is evident that the results calculated from the titration figures may not represent the true conditions (see remarks under POTASSII BROMIDUM).

Action and Uses.—Strontium iodide may be substituted for the other iodides to produce an iodine effect with less disturbance of digestion or depression of nutrition. Its dose is from 5 to 60 grains (0.30–4 Gm.) or more.

STRONTII SALICYLAS, *U. S.*—Strontium Salicylate.

Strontium salicylicum.—Salicylate de strontium, Fr.; *Salicylsaures Strontium, Strontiumsalicylat*, G.

Formula, $Sr(C_6H_4.OH.COO)_2 + 2H_2O$. Molecular weight, 394.72.

It should contain not less than 98.5 per cent. of the pure salt, and should be kept in well-stoppered bottles, protected from heat and light.—U. S.

Preparation.—Add 10 parts of salicylic acid to 100 parts of hot water, stir into this 5.34 parts of pure strontium carbonate, free from iron, and warm until effervescence ceases. Then filter and evaporate to crystallization.

Properties.—Strontium salicylate is a white, crystalline, odorless powder, having a sweetish, saline taste. It is soluble in 18 parts of water and in 66 parts of alcohol at 25° C. (77° F.), in 3.5 parts of boiling water, and in 10.5 parts of boiling alcohol. The aqueous solution should be slightly alkaline to litmus-paper and should be colorless. It imparts an intensely red color to a non-luminous flame, and when heated in a crucible it is decomposed, yielding inflammable vapors and an odor of phenol, and finally a gray residue of strontium carbonate. When warmed with an excess of concentrated sulphuric acid and a little methyl alcohol, the salt gives the characteristic odor of methyl salicylate.

Tests.—With ferric chloride a concentrated solution of the salt in excess produces a violet precipitate, but a very dilute solution (1 in 100) produces a deep violet-blue color. In an aqueous solution of the salt (1 in 20), copper sulphate solution produces a green color, calcium sulphate solution forms slowly, sulphuric acid quickly, a precipitate of strontium sulphate, potassium chromate forms yellow strontium chromate, soluble in acetic acid, and ammonium carbonate forms white strontium carbonate, soluble in acetic acid with effervescence. A solution of the salt from which the salicylic acid has been removed by acidifying with hydrochloric acid and filtering should not show the

presence of foreign substances when tested as described under STRONTIUM BROMIDE, 2 Gm. of the salt, heated with 10 Cc. of dilute acetic acid, cooled and filtered, should not become cloudy within 3 minutes upon addition of 5 drops of potassium dichromate test-solution (limit of barium). 0.5 Gm. of the salt, cautiously heated with 1 Cc. of sulphuric acid to dryness, moistened with the acid, and again heated to dryness, and finally ignited to constant weight, should leave a residue of not less than 0.227 Gm. of strontium sulphate, corresponding to 98.3 per cent. of pure salt. 394.72 Gm. of the salt will yield 182.29 Gm. of strontium sulphate, or 1 Gm. of the salt will yield 0.46182 Gm. of sulphate.

Action and Uses.—If strontium salicylate possesses any advantage over the other salicylates, it is that it is less irritating to the stomach. Its dose is from 5 to 30 grains (0.30–2 Gm.).

STRONTIUM.—Strontium.

Strontium, Fr., G.

Symbol, Sr. Valence, 2. Atomic weight, 86.94.

Strontium belongs to the family of alkaline earth metals. The general characteristics of these metals and their compounds have been touched on under CALCIUM, and need not be repeated here.

It occurs in nature much less abundantly than barium, the chief minerals being the sulphate, $SrSO_4$, known as celestite, and the carbonate, $SrCO_3$, known as strontianite. The latter is found in large quantities in Westphalia, Germany, and both minerals occur in Pennsylvania and New York; celestite is also found in Put-in-Bay Island, Lake Erie. Small quantities of sulphate and chloride are found in some springs and in the ashes of the bladder-wrack (Fucus vesiculosus) and other plants. It receives its name from strontianite, found near Strontian, in Argyleshire, Scotland. Strontium often accompanies barium and calcium in the carbonate and sulphate.

The metal is obtained from the chloride in the manner described under CALCIUM and BARIUM. It is very similar in its properties to calcium. Some of the differences are the following: Strontium compounds give an intensely red color to a flame; the sulphate is soluble in about 7000 parts of water, thus falling between calcium and barium in this respect; the chloride does not attract water as rapidly as calcium chloride and is soluble in absolute alcohol, thus differing from barium chloride, which is insoluble. Strontium carbonate is much more difficult to reduce to oxide by heat than is calcium carbonate.

Strontium salts are formed by neutralizing the respective acids with strontium carbonate and purifying by crystallization. Strontium sulphate is also employed by first reducing it to sulphide, which is then dissolved in acids. If the natural carbonate or sulphate is accompanied by calcium, barium, iron, magnesium, etc., these must be removed. One method of doing this was proposed by H. B. Dunham (1893) (see under STRONTIUM BROMIDE), another by Barthe and Falières (*Bull. Soc. Chim.*, 1892, p. 104), which consists in making ammoniacal a solution of strontium chloride to precipitate iron and alumina, adding to the filtrate excess of sulphuric acid, and washing the precipitated sulphates frequently with dilute sulphuric acid, then with water to remove calcium and magnesium. The precipitate is then digested for several days with 10 per cent. solution of potassium carbonate, which converts strontium sulphate into carbonate, washed and treated with hydrochloric acid, which dissolves out the strontium carbonate. The filtrate of strontium chloride is strongly acidified with hydrochloric acid and digested with several grammes of precipitated strontium sulphate, which removes the last traces of barium, after which it is filtered and evaporated to dryness. The salt is then dissolved in three times its weight of water, allowed to stand a day, filtered if necessary, and evaporated to crystallization. This yields a pure chloride, from which the carbonate can be obtained by precipitation, which serves as the starting-point for any other salt.

STRONTIUM OXIDE AND HYDROXIDE.—The oxide, SrO, is not easily obtained by heating strontium carbonate, but forms readily by heating the nitrate. It is like calcium oxide, and combines with water to form the hydroxide, which is easily soluble in hot water, and on cooling crystallizes out as $Sr(OH)_2.8H_2O$. These crystals effloresce much more easily than do those of barium hydroxide. For the preparation of pure strontium hydroxide, see under STRONTIUM BROMIDE. Most of the strontium com-

pounds in nature are converted into the hydroxide, which finds great application in the sugar industries, since it combines with cane-sugar to form difficultly soluble crystalline compounds, and thus it is possible to extract sugar from molasses after it can no longer be obtained by crystallization. The saccharine compound is then decomposed by carbon dioxide, which forms strontium carbonate and liberates the sugar.

STRONTII NITRAS.—*Strontium Nitrate*, $Sr(NO_3)_2$.—Colorless octahedral crystals, soluble in 5 parts of cold, 0.5 part of hot water, slightly soluble in alcohol, but not in absolute alcohol. Crystallized from concentrated hot solution, it is anhydrous; but from cold dilute solutions, $Sr(NO_3)_2 + 4H_2O$ or $5H_2O$ is formed. It is manufactured in considerable quantity as a constituent of *red-fire* or *Bengal-fire*, which consists of a mixture of 56 parts of strontium nitrate, 24 parts of flowers of sulphur (or shellac), and 20 parts of potassium chlorate, or 100 of strontium nitrate, 10 of wood charcoal, and 100 of potassium chlorate. Caution in mixing must be observed.

STRONTIUM GLYCEROPHOSPHATE is similar to the calcium salt (which see). It is a white powder, soluble in water, and precipitated from solution on warming and also by various salts. It contains 26 to 27 per cent. of phosphoric acid.

STRONTII LACTAS.—*Strontium lactate*, E.; *Lactate de strontium*, Fr.; *Strontium-lactat, Milchsaures Strontium*, G. $Sr(C_3H_5O_3)_2.3H_2O$.—Strontium lactate is made from the carbonate by dissolving it in lactic acid somewhat diluted with water; if necessary heat is applied to effect solution. After filtration the solution is evaporated with moderate heat to dryness. Like strontium bromide and iodide, the lactate is readily made from the hydroxide by addition to lactic acid until a neutral solution is obtained, and evaporating this to dryness. Strontium lactate occurs as a white granular powder or in crystalline nodules, odorless, and of a slightly bitter, saline taste. The salt is permanent in the air, and soluble in 4 parts of water at 15° C. (59° F.), and in less than 0.5 part of boiling water. The salt is also soluble in alcohol. Its reaction is slightly acid. When heated to 110° C. (230° F.), it loses its water (16.9 per cent.); at a higher temperature it first fuses, then is decomposed, and leaves a residue of strontium carbonate and carbon. If to 5 Cc. of a 5 per cent. aqueous solution of the salt 1 Cc. of sulphuric acid be added, and then 1 Cc. of tenth-normal potassium permanganate solution, the red color will rapidly disappear, while the mixture will effervesce and give off the odor of aldehyde. The salt should respond to the tests of purity given under STRONTIUM BROMIDE. If 0.5 Gm. of the salt be placed upon a watch-glass, and 1 Cc. of sulphuric acid be carefully poured upon it, no effervescence should occur (absence of carbonate, oxalate, etc.); nor should any penetrating odor be perceptible, even after gentle heating (absence of butyrate, propionate, etc.); nor should the acid assume, within ten minutes, a deeper color than a pale straw-yellow (limit of readily carbonizable organic impurities).

Action and Uses.—The belief in the toxicity of strontium and its salts was disproved by Laborde in 1890, who demonstrated that they were not only innocuous, but exercised favorable nutritional influences over the body. He ascribed to them diuretic properties, which are shared most largely by the lactate. From subsequent studies, Seé, Dujardin-Beaumetz, and others conclude that strontium lactate is a valuable remedy to reduce the albuminuria of chronic parenchymatous nephritis, but is less efficient in the interstitial variety. It does not increase urinary flow. The salt has not produced uniformally good results, for its use has been disappointing in the hands of many careful clinicians. The dose of strontium lactate is from 20 to 60 grains (1.30–4 Gm.). Strontium glycerophosphate is used like the calcium salt in the dose of 5 to 10 grains (0.30–0.60 Gm.).

STROPHANTHINUM, *U. S.*—Strophanthin.

Strophantine, Fr. Cod.; *Strophanthin*, G.

Formula, $C_{31}H_{48}O_{12}$ (Fr. Cod.); $C_{30}H_{46}O_{12} + 9H_2O$ (Thoms). Molecular weight, 607.77? or 745.78?

The U. S. Pharmacopœia does not give a chemical formula for strophanthin, and defines the latter to be a glucoside or mixture of glucosides obtained from strophanthus. Since Strophanthus Kombé is the variety officially recognized, the glucoside must be assumed as obtained from it. Considerable confusion and uncertainty exists regarding the character of the strophanthin obtained from different species of strophanthus, and the various data published by different authors must be accepted tentatively, at

least for the present. (See also Constituents under STROPHANTHUS.) H. Thoms has recently (1904) reviewed the work of previous authors, and found the strophanthin obtained by him from *Strophanthus Kombé* to contain small proportions of nitrogen, which he traced to the presence of choline and trigonelline, the latter substances having also subsequently been found in the seed of the same variety. On the other hand, strophanthin obtained from the seed of *Strophanthus hispidus* was free from nitrogen, but it was found impossible to induce crystallization in solutions of the same. The same author, operating with a carefully determined specimen of *Strophanthus gratus*, succeeded in obtaining as much as 3.615 per cent. of crystallized strophanthin, also free from nitrogen, which, after recrystallization, was found to have the composition given in the formula above stated. The high therapeutic value of the *gratus-strophanthin* having been established by numerous pharmacological experiments, Thoms advises the introduction of this variety into medicine in place of the more uncertain and varying strophanthins from other sources, and further suggests that the different strophanthins be distinguished by prefixing the initial letter indicating the source to the name thus: *k-strophanthin*, *h-strophanthin*, *g-strophanthin*, referring to strophanthin from the *Kombé*, *hispidus*, and *gratus* variety of strophanthus seed respectively.

Preparation.—The finely pulverized seeds of strophanthus are exhausted with ether or petroleum benzin to remove fat, and then extracted with 70 per cent. alcohol. From the tincture thus obtained the alcohol is recovered by distillation, and the residuum dissolved in water and filtered. Tannic acid is added to the filtrate, the resulting precipitate washed, mixed with litharge, dried, and then exhausted with alcohol. The addition of ether to the alcoholic solution will cause the strophanthin to be precipitated. This is essentially the process of Fraser, who first extracted strophanthin from the seed in 1886.

Properties and Tests.—A white or faintly yellowish crystalline powder, containing varying amounts of water of crystallization, which it does not lose entirely without decomposition. Taste intensely bitter; great caution should be used in tasting it. Permanent in the air. It is very soluble in water and in diluted alcohol, less soluble in absolute alcohol, but nearly insoluble in ether, chloroform, and benzene. When heated, it begins to fuse at 170° C. (338° F.), and is not completely melted until the temperature of 190° C. (374° F.) is reached. Its solutions are detrogyrate, bitter and neutral to litmus-paper. Sulphuric acid produces with strophanthin an emerald-green color, changing to brown. If to an aqueous solution of strophanthin a trace of ferric chloride test-solution and a few Cc. of sulphuric acid be added, a red-brown precipitate will be produced, turning dark green after one or two hours. Strophanthin should not reduce alkaline cupric tartrate solution; if its solution be heated to 70° C. (158° F.) with a small amount of diluted hydrochloric acid (1 in 20), it will be decomposed into strophanthidin, which precipitates, and a sugar which will remain in solution, and which will reduce alkaline cupric tartrate solution.—U. S.

Strophanthin is extremely toxic. In contact with concentrated acids, it is rapidly decomposed. By heating strophanthin with dilute (10 per cent.) mineral acids, various shades of a green color, changing to violet or blue, are produced, and are more or less characteristic. Strophanthin is precipitated by tannic acid, but not by other alkaloidal reagents. Thoms gives the following properties for the glucoside obtained by him from strophanthus gratus: When anhydrous it melts at 187° to 188° C. (368.6° to 370.4° F.). It requires for solution 100 parts of water, or 30 parts of amyl alcohol, or 30 parts of alcohol, and is very sparingly soluble in ether, chloroform, aud acetic ether. In contact with concentrated sulphuric acid it produces a red color, which, on dilution with water, changes to green with the separation of a greenish-white flocculent deposit.

Action and Uses.—Until some uniformity in the strength of strophanthin be established it would seem an unsatisfactory drug to employ unless the activity and dose of each individual sample be ascertained. It fully represents the crude drug in its action. The average dose is from $\frac{1}{300}$ to $\frac{1}{200}$ grain (0.0002–0.0003 Gm.).

STROPHANTHUS, *U. S.*—Strophanthus.

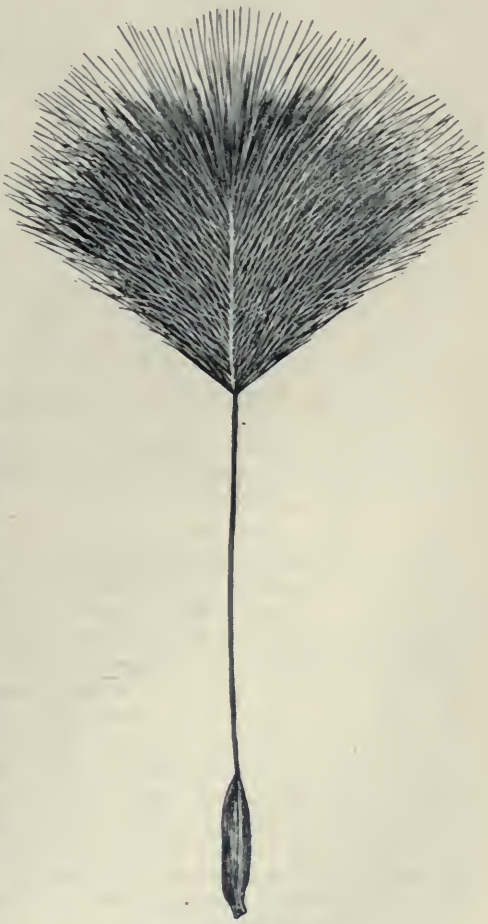
Strophanthi semina, Br.; *Semen strophanthi*, P. G.; *Strophanthus-seed*, E.; *Strophanthussamen*, G.; *Semence de strophanthus*, Fr.; *Semi di strofante*, It.

The dried, ripe seeds of *Strophanthus Kombé* Oliver (*S. hispidus Kombé* Oliver.—Fam. *Apocynaceæ*), deprived of their long awns.

Strophanthus is official in all pharmacopœias, a number of which retain the synonym given the plant when it was not yet recognized as being distinct from that to which the synonym belongs.

Origin.—Strophanthus is the product of a rough-leaved, woody twiner of eastern tropical Africa. Apparently, different species grow in the same vicinity, as is usual with the twiners of this family, this probably accounting in great part for the fact that the commercial seeds are usually contaminated with those of other species. The drug was first made known by the reference to it of samples of an arrow-poison made by the natives of the region where it grows, the sample having been sent to England for examination. The seeds grow in follicles, of which each flower produces two, and which are from 12 to 16 inches in length and an inch in thickness, acuminate, and somewhat acute. The pericarp of the genuine is thin and only slightly fleshy, and contains numerous seeds imbedded in a mass of overlapping, straight, silky, white hairs, which consist of the long plumose awns in which the seeds terminate. The seeds are exported either within the follicles or after removal. The former method is preferable, since it allows of more effective provisions against admixture. In this case the fleshy outer portion is usually first removed. When the seeds alone are exported, the awns are commonly first removed.

Fig. 415.



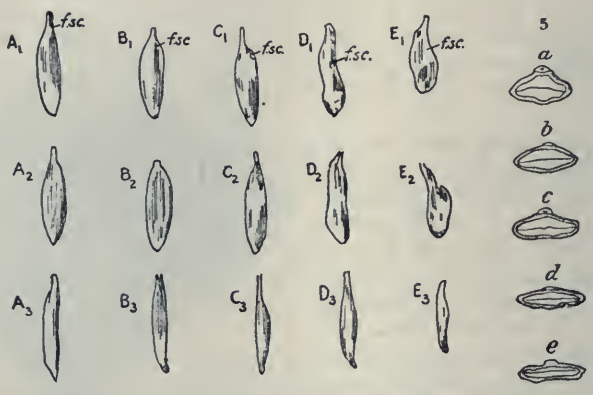
Strophanthus (Nat.).

Description.—Of a light or fawn brown, with a distinct greenish tinge; about 15 Mm. ($\frac{3}{5}$ In.) long and 4 or 5 Mm. ($\frac{1}{6}$–$\frac{1}{5}$ In.) thick in one direction, half as much in the other, lance-oblong, obtuse at the base, acuminate and acutish at the summit, distinctly compressed, usually slightly twisted, bearing a ridge which runs along the upper half or more of one side; silky lustrous from a dense coating of hairs, which mostly lie in longitudinal grooves of the surface, and are closely appressed; fracture short and somewhat soft, the fractured surface whitish and oily; kernel consisting of a thin endosperm enclosing straight cotyledons; odor slight, or heavy when the seeds are crushed; taste very bitter. The endosperm quickly assumes a green color upon treatment with concentrated sulphuric acid, and the cotyledons often do the same, in parts. The powder is pale brown and exhibits numerous hairs of a light greenish-brown color, 1 Mm. ($\frac{1}{25}$ In.) or less in length, consisting of but one cell, its walls thin; starch-grains occur sparingly, mostly compound, 10 mikrons or less in diameter. A decoction prepared with 1 part of the seed and 10 parts of water has a pale-brownish color, and is not changed in appearance on the addition of iodine test-solution, ferric chloride test-solution, or potassium mercuric iodine test-solution.

Adulteration.—To how great an extent the admixture of other seeds with official strophanthus is the result of intentional adulteration cannot be stated. That much of it

is so is certain. The adulterants reported are the seeds of other species of strophanthus and of *Kickxia Africana* Benth., in the same family. The most common and serious adulterant—more often wholly substituted than admixed—is the seed of *S. hispidus* D. C., the so-called *Brown strophanthus.* This grows in West Africa, and there is little excuse for its gaining access to the official drug. The seed is dark brown, averages a third shorter and relatively stouter than the official, and has a shorter and more abruptly contracted point. The hairs are much fewer, shorter, and stouter, and regularly arranged. These seeds, when crushed, give a red coloration on treatment with concentrated sulphuric acid. Another brown seed is that of "*S. gratus,*" readily distinguished by the absence of hairs. "*S. asper*" has a covering of nearly white hairs, which are several times longer than those of *S. Kombé,* and spread somewhat from the surface, giving a

FIG. 416.



Variations in size and form of Strophanthus Kombé seeds (after Perrédès).

semi-shaggy appearance and causing the seed to appear much stouter than it really is. This is known commercially as *White woolly strophanthus,* and is thought to be derived from *S. Nicholsonii* Holmes.

Still another is that of *S. Courmontii Kirkii* Holmes, which is similar to that of *S. hispidus,* has the ventral ridge obscure or wanting, and shows numerous prismatic crystals of calcium oxalate. This plant has smooth leaves and thick pods, usually less than a foot long. It grows with *S. Kombé,* and the seeds are readily mixed. Kickxia seeds are acuminate at both ends, terete, and hairless.

Constituents.—The constituents of minor importance are 25 to 30 per cent. of fixed oil, choline and trigonelline, little starch, proteids, and other ordinary constituents. The active part consists of one or more glucosides, concerning which our information is most indefinite. This indefiniteness unquestionably proceeds from the universal use of contaminated seeds in the examinations made, and we cannot hope that the subject will be cleared up until botanically pure material shall have been secured. The yield of glucoside has been reported variously, from about 1 to nearly 3 per cent. The glucoside of *S. Kombé* appears to be wholly *strophanthin,* which readily decomposes, yielding *strophanthidin,* on which account great care has to be employed in extracting it, acids not being employed in the process. It is this glucoside to which the green reaction of the crushed seeds with sulphuric acid is due, this constituting its best identification test. The best study of it has been by Feist, who assigns the formula, in the anhydrous state, $C_{40}H_{66}O_{19}$, yielding *strophanthidin* ($C_{27}H_{38}O_7 + 2H_2O$) and *strophanthobiose-methyl-ether* ($C_{12}H_{21}O_{10}CH_3$). It melts at 170° to 172° C. (338°–341.6° F.), and has an optical rotation of +10 in 5 per cent. solution. When warmed slowly with a 0.5 per cent. solution of hydrochloric acid, strophanthidin separates suddenly, at 70° to 75° C. (158°–167° F.), in fine needles. Feist's strophanthin is the same as that of Fraser. The source of another glucoside, *pseudo-strophanthin,* cannot be asserted with our present knowledge. It is apparently present in several species, but perhaps not in *S. Kombe.* It is twice as active as strophanthin, though it is by no means certain that the action is the same, and there are indications that it is more irritating to the heart without a corresponding gain in tonic properties. It is said to be present in the brown seeds, but this

is quite indefinite; some brown seeds, certainly, are almost inert. It also appears to be present in the white seeds. This glucoside Feist regards as being the methyl-ether of a substance ($C_{29}H_{33}O_6$) containing one oxygen atom less than strophanthidin. It gives a red coloration with sulphuric acid, melts at 179° C. (354.2° F.), has a slight lævogyre rotation, and hydrolyzes at 100° C. (212° F.) with a 2.4 per cent. solution of hydrochloric acid. Feist is sure that this is the same as the "strophanthin" of Arnaud, but not the same as his ouabain.

The fixed oil of strophanthus is brownish green, of a heavy odor, non-drying, congealing at —6° C. (21.2° F.) and melting again at +2° C. (35.6° F.), specific gravity 0.9249, acid number 24.3, ester number 170.3, saponification number 194.6, iodine number 101.6, Reichert's number 0.9, Hehner's number 94.1. It contains small quantities of volatile oil, phytosterin, formic acid, and one other volatile fatty acid, its primary components being oleates, stearates, and arachinates (*Bjalobestzesky*). It has been thought by some that the irritating properties of some strophanthus seeds were due to their fixed oil.

Pharmaceutical Preparation.—Tincture of Strophanthus, U. S. P.

Action and Uses.—The physiological action of strophanthus is nearly related to that of digitalis in that its use results in an increase in the pulse force and volume, a rise of arterial pressure and a slowing of the pulse. The increased pulse force and volume is due to stimulation of the heart muscle and the use of arterial pressure is also chiefly due to this cause, since strophanthus does not stimulate the muscular coats of the bloodvessels as does digitalis. The moderate slowing of the pulse is not due to stimulation of the vagus nerves. Given in full doses the drug is capable of causing gastro-intestinal inflammation and diarrhœa. When poisonous doses are taken it causes death by arrest of the heart in systole. By reason of its stimulant effect on the heart it indirectly increases urinary flow. The therapeutic uses of strophanthus are identical with those of digitalis (see Digitalis), and its lack of power over the muscular coats of the bloodvessels makes it particularly useful in those cases in which the heart is feeble and the arterial tension high. It also seems to act better in cases of ruptured compensation in valvular disease in children than does digitalis. The dose of powdered strophanthus seeds is ½ to 1 grain (0.03–0.06 Gm.), of the extract ¼ to 1 grain (0.015–0.06 Gm.), and of the tincture 5 to 15 minims (0.3–1 Cc.) three times a day.

STRYCHNINA, *U. S., Br., Fr. Cod.*—Strychnine.

Strychninum.—Strychnine, Fr.; *Strychnin*, G.

An alkaloid obtained from Nux Vomica, and also obtainable from other plants of the Loganianaceæ.—U. S. An alkaloid obtained from the dried ripe seeds of Strychnos Nux Vomica, *L.*, and other species of Strychnos.—Br.

Formula, $C_{21}H_{22}N_2O_2$. Molecular weight, 331.73.

The alkaloid strychnine was discovered by Pelletier and Caventou in 1818.

Preparation.—Very few pharmacopœias give a process for the manufacture of strychnine, but the French Codex gives the following directions: Powdered nux vomica is to be exhausted with boiling alcohol, the alcohol to be subsequently recovered and the residue taken up with very dilute sulphuric acid. After filtration slaked lime is added to the acid liquid, the resulting precipitate collected, dried, and exhausted with hot alcohol. The alcoholic solution is filtered, concentrated, and allowed to cool, when fairly pure strychnine will be deposited. The crude alkaloid is dissolved in water with the aid of diluted nitric acid and the solution allowed to crystallize, any brucine present remaining in the mother-liquor. From the strychnine nitrate thus obtained, the pure alkaloid may be precipitated by adding ammonia-water to its solution in water, and may then be crystallized from boiling alcohol upon cooling.

The following process has been used commercially and differs from the preceding chiefly in extracting the alkaloids as sulphates or hydrochlorides by means of boiling acidulated water instead of exhausting the seed with alcohol.

Powdered nux vomica, or the drug softened by steam and while hot crushed between rollers, is exhausted by boiling with very dilute hydrochloric or sulphuric acid; the decoction contains the alkaloids as hydrochlorides or sulphates, together with the liberated igasuric acid, mucilaginous compounds, coloring matter, and other principles. On

the addition of slaked lime the salts of alkaloids are decomposed, calcium chloride or sulphate is formed, and strychnine and brucine are precipitated, together with the excess of lime employed, and with calcium sulphate On washing this precipitate with water, the foreign principles are mostly removed, and by treatment with cold diluted alcohol the brucine is dissolved. The residue now consists essentially of lime and strychnine, the latter of which is taken up by boiling alcohol, and further purified by converting it into sulphate soluble in water, decolorizing with animal charcoal, and precipitating with an alkali; or, the washed and dried precipitate by lime is at once exhausted with boiling alcohol, and the mixed strychnine and brucine are purified by treatment with sulphuric acid, animal charcoal, and ammonia, and separated by dissolving in hot alcohol, when, on cooling, strychnine will crystallize and brucine remain in the mother-liquor.

Various other processes have been proposed, differing mainly in the manner in which the alkaloids are liberated and afterward separated from each other. Magnesia or sodium carbonate may be substituted for the lime and ammonia in the above processes; and benzene was suggested by Boiraux and Léger (1875) for dissolving strychnine from the mixed alkaloids, brucine, it is stated, being completely insoluble in that menstruum.

Properties and Tests.—Colorless, transparent, prismatic crystals, or a white crystalline powder; odorless, and having an intensely bitter taste, perceptible even in solutions of 1 in 700,000. Permanent in the air. Soluble in 6400 parts of water, 110 parts of alcohol, 5500 parts of ether, 6 parts of chloroform, 150 parts of benzene, and in 180 parts of amyl alcohol at 25° C. (77° F.); soluble in 3000 parts of water at 80° C. (176° F.), and in 28 parts of alcohol at 60° C. (140° F.). Its melting point is 268° C. (514.4° F.). Upon ignition it is consumed, leaving no residue. Its solutions are lævogyrate and alkaline to litmus-paper. Sulphuric acid containing 1 per cent. of ammonium vanadate produces with strychnine a deep violet blue color, changing to a deep purple, and finally to a cherry-red. Sulphuric acid containing a trace of potassium iodate produces a violet color, changing momentarily to reddish purple. If 0.1 Gm. of strychnine dissolved in a few drops of nitric acid be evaporated to dryness, and a few drops of ammonia-water added to the yellow residue, an orange color will be produced, which will turn reddish-purple, and finally brown, on the addition of a small amount of alcoholic potassium hydroxide test-solution. Sulphuric acid should produce no color (absence of sugar and other readily carbonizable organic impurities), but on adding a fragment of potassium dichromate, a deep-blue color is momentarily produced, changing to deep violet, then to purplish red, cherry-red, and finally to orange or yellow. Nitric acid, when added to a crystal of strychnine on a white porcelain surface, should not produce more than a faintly pink color (limit of brucine).—U. S.

Strychnine is soluble at 15° C. (59° F.) in 6700 parts of water; in 207 parts of absolute alcohol; in 150 parts of 90 per cent. alcohol; in 400 parts of common whisky (Wormley); in about 500 parts of alcohol of specific gravity 0.941, and in 2617 parts of specific gravity 0.970 (Prescott and Smith): in 165 parts of benzene; in 1250 parts of commercial ether (Draggendorff); in 12,500 parts of petroleum benzin (Wormley); in 300 parts of glycerin; and also soluble to some extent in volatile and fixed oils and in creosote. It dissolves in 2500 parts of boiling water; in 12 parts of boiling alcohol, and in 40 parts of boiling absolute alcohol. Its solubility in water is not increased by ammonia or caustic alkalies, but dilute acids render it much more soluble with the formation of neutral salts, which are mostly crystallizable, and from the solutions of which the alkaloid is precipitated by alkali hydroxides, alkali carbonates, chromates, and, after some time, by soluble bicarbonates. The solutions of strychnine are lævogyre in their action on polarized light. Chloroform forms a crystalline compound, $C_{21}H_{22}N_2O_2.HCl,CHCl_3$, when a chloroform solution of strychnine is subjected to prolonged heating at 150° C. (302°F.). The chloroform is entirely expelled from the crystals at 100° C. (212° F.). In drying the strychnine obtained from chloroform solution the decrepetation of the residue may be prevented by adding a few Cc. of amyl alcohol to the chloroform solution previous to evaporating. Strychnine combines with iodoform to form the reddish-brown crystalline compound $3C_{21}H_{22}N_2O_2.CHI_3$ (Lextreit, 1881; P. F. Trowbridge, 1899). The salts of strychnine yield precipitates generally in very dilute solutions with the alkaloidal reagents. With phosphomolybdic acid (Sonnenschein's reagent) a yellowish-white amorphous precipitate is obtained, which is soluble in ammonia to a colorless solution. Phosphotungstic acid yields a white precipitate in solutions containing 1 part of strychnine in 200,000 parts of acidulated water. Potassio-iodide of bismuth

gives a brown precipitate in dilutions of 1:250,000; potassio-mercuric iodide, a white precipitate in dilutions of 1:150,000; picric acid, a yellow crystalline precipitate in dilutions 1:20,000; potassium ferrocyanide, a white crystalline precipitate in solutions of 1:100,000. Solution of iodine in potassium iodide gives a reddish-brown precipitate in solutions of 1:100,000. The precipitate is soluble in alcohol from which it may be recovered in characteristic microscopic crystals on slow evaporation of the alcohol. In solutions containing 1 part of a salt of strychnine in 1000 parts of water potassium dichromate precipitates, after some time, characteristic microscopic crystals of strychnine dichromate, $2C_{21}H_{22}N_2O_2.H_2Cr_2O_7$.

When fused with potassium hydroxide strychnine yields quinoline and indole. By electrolytic reduction (J. Tafel, Annalen, 1898, pp. 285–348) strychnine yields according to conditions varying amounts of the toxic bases *tetrahydrostrychnine*, $C_{20}H_{22}NO(NH).CH_2.OH$, and *strychnidine*, $C_{21}H_{22}NO\ (N).CH_2$, the latter being derived from the former by separation of water.

Strychnine dissolves in concentrated sulphuric acid without color. On continued heating of the sulphuric acid solution at 100° C. (212° F.) strychnine-monosulphonic acid $C_{21}H_{21}N_2O_2.HSO_3$ is formed (C. Stoehr). This acid is difficultly soluble in water and alcohol, forms a soluble salt with ammonia, and difficultly or insoluble salts with sodium, potassium, lead, barium, calcium, and copper. Strychnine dissolves in dilute nitric acid without color and without decomposition (distinction from brucine), but in concentrated nitric acid a yellow color results and the strychnine is partly decomposed with the formation of picric acid.

Strychnine is generally identified by the characteristic play of colors, beginning with a deep bluish purple and fading rapidly to an orange shade, varying somewhat for the different oxidizing agents used, when strychnine is dissolved (colorless) in sulphuric acid and treated with a fragment of potassium dichromate, etc. Peroxide of lead produces a blue color, passing into violet, red, and finally into yellow (Marchand). Potassium dichromate produces a blue or a deep violet, fading rapidly to an orange shade. A similar play of colors is produced by potassium ferricyanide, but the colors fade more slowly (Davy). The solution of strychnine in sulphuric acid containing some nitric acid yields on the addition of manganese dioxide a purplish-violet color (Mack, Erdmann), and a similar color, but rapidly fading to yellow, is produced with chloric, chlorius, and iodic acids and their salts, and with manganic sulphate and potassium permanganate. Cerosoceric acid (Sonnenschein) produces a blue color which changes slowly to violet, and finally cherry-red, and is one of the most satisfactory reagents for producing the color reactions. When pure 0.0025 Mgm. of strychnine is readily identified by the above tests. The reaction is, however, interfered with by chlorides, nitrates, organic matter, and particularly sugar, and the alkaloids brucine and morphine. If much contaminated with organic matter, the alkaloid is best purified by dissolving it in dilute acid, so as to free it from fatty and resinous matters, filtering through a wet filter, liberating it by adding ammonia, and dissolving it by agitation with chloroform; if necessary, the process is repeated, and the residue from the evaporation of the chloroform is tested as above.

A mixture of strychnine nitrate and copper nitrate turns violet on the addition of stannous chloride, and becomes green on drying. Strychnine when evaporated with potassium hydroxide yields a dark-blue residue on the addition of stannous chloride. Potassium persulphate and hydrochloric acid give no color reaction with strychnine in the cold, whereas brucine gives a deep-red color (C. Reichard). The peculiar reaction (J. Uri Lloyd) produced by a mixture of hydrastine and morphine when tested with potassium dichromate in sulphuric acid solution is not readily mistaken for the strychnine reaction (Wharton and S. Williams, *Drug. Circ.*, 1901, p. 48).

Action and Uses.—The physiological action and therapeutic application of strychnine are considered under NUX VOMICA (which see). The alkaloid is almost always prescribed in the form of one of its salts. Its dose is from $\frac{1}{160}$ to $\frac{1}{20}$ grain (0.0006–0.003 Gm.).

STRYCHNINÆ HYDROCHLORIDUM, *Br.*—Strychnine Hydrochloride.

Strychninum hydrochloricum.—Chlorhydrate de strychnine, Fr.; *Strychninhydrochlorid, Salzsaures Strychnin*, G.

Formula, $C_{21}H_{22}N_2O_2.HCl + 2H_2O$. Molecular weight, 403.67.

The hydrochloride of an alkaloid obtained from nux vomica and from other species of strychnos.—Br.

Preparation.—Strychnine hydrochloride may be prepared by suspending 5 Gm. of strychnine alkaloid in 50 Cc. of hot distilled water, adding 2.2 Gm. of 25 per cent. hydrochloric acid, or 5.5 Gm. of official diluted hydrochloric acid, and heating until perfect solution is effected. The liquid is then concentrated and allowed to crystallize.

Properties and Tests.—Strychnine hydrochloride occurs in small colorless trimetric prisms which readily effloresce in the air; soluble in 35 parts of water or in 60 parts of alcohol (90 per cent.), forming a solution which is neutral to litmus and intensely bitter to the taste. The salt should afford the reactions characteristic of hydrochlorides, and should respond to the qualitative tests mentioned under "Strychnina," but should not yield any characteristic reaction for sulphates. Dried at a temperature of 100° C. (212° F.) it should lose 7.3 to 8.8 per cent. of moisture.—Br.

Since the salt effloresces readily, it should be kept in well-stoppered bottles in a cool place. The amount of water, 2 molecules, given in the formula above corresponds to 8.85 per cent. Strychnine hydrochloride contains 82.17 per cent. of strychnine.

Action and Uses.—For the action and uses of strychnine see article on Nux Vomica. The hydrochloride is given in the dose of from $\frac{1}{100}$ to $\frac{1}{20}$ grain (0.0006–0.003 Gm.).

STRYCHNINÆ NITRAS, *U. S.*—Strychnine Nitrate.

Azotate de strychnine, Fr. Cod.; *Strychninum nitricum*, P. G.—*Nitrate de strychnine*, Fr.; *Strychninnitrat, Salpetersaures Strychnin*, G.

Formula, $C_{21}H_{22}N_2O_2.HNO_3$. Molecular weight, 394.30.

The nitrate of the alkaloid strychnine.—U. S.

Preparation.—With the exception of the French Codex, the pharmacopœias do not give a process of manufacture. The former simply directs that a convenient quantity of strychnine alkaloid be triturated with nitric acid diluted with 5 times its weight of water, added in small quantities until a neutral solution is obtained. 5 Gm. of strychnine may be suspended in 50 Cc. of hot distilled water and diluted nitric acid be added in sufficient quantity. After a neutral solution has been obtained, it should be concentrated and allowed to crystallize. Theoretically 1 Gm. of the alkaloid requires 1.886 Gm. of the official diluted acid for combination.

Properties and Tests.—Strychnine nitrate occurs in colorless, glistening needles, which are odorless, having an intensely bitter taste, and are permanent in the air. Soluble in 42 parts of water, 120 parts of alcohol, 156 parts of chloroform, and in 60 parts of glycerin at 25° C. (77° F.); soluble in 8 parts of water at 80° C. (176° F.), and in 60 parts of alcohol at 60° C. (140° F.); insoluble in ether. When heated the salt decomposes, but it does not melt, and when ignited it is consumed without leaving a residue. Its aqueous solutions are neutral to litmus-paper, and lævogyrate. A solution of the salt, when poured carefully into a test-tube upon a layer of sulphuric acid containing in solution a little diphenylamine, will develop a blue zone at the juncture of the two liquids. On being heated with hydrochloric acid a bright red color is formed. Sulphuric acid containing 1 per cent. of ammonium vanadate produces with strychnine nitrate a dark violet blue color, changing to purple, and then to red. Sulphuric acid containing a trace of potassium dichromate produces momentarily a blue color, changing to violet, then to purplish red, cherry-red, and finally to orange or yellow. If 0.1 Gm. of the salt, dissolved in a few drops of nitric acid, be evaporated to dryness, and a few drops of ammonia-water added to the residue, an orange color will be produced, which will turn reddish purple, and finally brown, on the addition of a small amount of alcoholic potassium hydroxide test-solution. The addition of sulphuric acid to a crystal of strychnine nitrate on a white porcelain surface should not produce more than a faintly yellow color (limit of brucine).—U. S.

The German Pharmacopœia gives the solubility of strychnine nitrate as 1 part in 90 parts of cold and 3 parts of boiling water, or in 70 parts of cold and 5 parts of boiling alcohol. If the salt be boiled with hydrochloric acid a red color is developed. It dissolves in concentrated nitric acid with a yellow color, but no red color should develop. Strychnine nitrate should dissolve in sulphuric acid without color, and gives the charac-

teristic reaction for nitrates and for strychnine. The salt contains 84.13 per cent. of strychnine.

Action and Uses.—The dose of strychnine nitrate is from $\frac{1}{100}$ to $\frac{1}{20}$ grain (0.0006–0.003 Gm.) (see NUX VOMICA).

STRYCHNINÆ SULPHAS, *U. S.*—Strychnine Sulphate.

Strychninum sulfuricum.—Sulfate de strychnine, Fr. Cod.; *Strychninsulfat, Schwefelsaures Strychnin*, G.

Formula, $(C_{21}H_{22}N_2O_2)_2H_2SO_4 + 5H_2O$. Molecular weight, 850.21.

The sulphate of the alkaloid strychnine.—U. S.

Preparation.—Strychnine sulphate is best prepared by adding strychnine in powder form in slight excess to warm diluted sulphuric acid; the filtrate from the undissolved alkaloid will yield the salt on being evaporated spontaneously to dryness, or the filtrate may be concentrated and then allowed to crystallize. In the latter case it will contain 5 molecules of water. The form of crystal and the amount of water of crystallization may vary with the mode of preparation.

Properties and Tests.—Strychnine sulphate occurs as colorless, or white prismatic crystals, or a white, crystalline powder; odorless, and having an intensely bitter taste, perceptible even in solutions of 1 in 700,000. Efflorescent in dry air. Soluble in 31 parts of water, 65 parts of alcohol, and in 325 parts of chloroform at 25° C. (77° F.), soluble in 6 parts of water at 80° C. (196° F.), and in 20 parts of alcohol at 60° C. (140° F.); insoluble in ether. When heated at 100° C. (212° F.), the salt loses its water of crystallization (10.59 per cent.), and when anhydrous melts at 200° C. (392° F.). Upon ignition it is consumed, leaving no residue. Barium chloride test-solution produces in a solution of the salt a white precipitate, which is insoluble in hydrochloric acid. Sulphuric acid should produce no color with strychnine sulphate, but on adding a fragment of potassium dichromate, a blue color should be formed, changing to deep violet, then to purplish red, cherry-red, and finally to orange or yellow. Sulphuric acid containing 1 per cent. of ammonium vanadate produces a deep violet-blue color, changing to deep purple, and finally to cherry-red. Sulphuric acid containing a trace of potassium iodide produces a violet color, changing to reddish purple. If 0.1 Gm. of the salt be dissolved in a few drops of nitric acid, evaporated to dryness, and a few drops of ammonia-water added to the yellow residue, an orange color will be produced, which will turn momentarily reddish purple, and finally brown, on the addition of a small amount of alcoholic potassium hydroxide test-solution. Nitric acid, when added to a crystal of strychnine sulphate on a white porcelain surface, should not produce more than a faintly yellow color (limit of brucine).—U. S.

The official strychnine sulphate contains 78.03 per cent. of strychnine. At ordinary room temperature a fluidounce of water will dissolve nearly 15 grains of the salt.

Action and Uses.—The sulphate is the salt of strychnine commonly employed. Its properties are considered under NUX VOMICA (which see). It is given in the dose of $\frac{1}{100}$ to $\frac{1}{20}$ grain (0.0006–0.003 Gm.).

STYRAX, *U. S., P. G.*—Storax.

Styrax liquidus, Balsamum styracis, Balsamum styrax liquidus.—Liquid storax, E.; *Styrax liquide*, Fr.; *Flüssiger Storax*, G.; *Stirace, Storace Liquido, Balsamo Storace*, It.; *Estoraque Liquido*, Port., Sp.

A liquid balsam obtained from the wood and the inner bark of *Liquidamber orientalis* Mill. (*Platanus o.* Pecocke, *L. imberbe* Ait.—Fam. *Hamamelidaceæ*).

Purified by solution in alcohol, filtration, and evaporation, it is the *Styrax præparatus* of the Br. P.

Styrax is official in all pharmacopœias. The Belgian names *L. styraciflua* L. as its source.

Origin.—Styrax is obtained by the Yuraks from a forest tree of southwestern Asia Minor, very similar to the North American sweet gum tree. Like other and similar substances, this balsam is not a natural part of the plant, but is produced as a result of the stimulus from wounds in the bark, apparently nature's method to secure antisepsis and to promote healing. To secure the balsam, the outer bark is bruised on one side of the

tree, as a result of which the inner layers become saturated with this pathological exudation. The dead outer bark is later removed and rejected, and the inner is removed and boiled in sea-water, the storax being skimmed off the surface as it rises, and receiving some inorganic additions from the sea-water. An additional quantity is afterward pressed out from the boiled bark. The latter, which is still partly charged with the balsam, is dried and utilized in various ways, especially for burning as incense, and has occasionally found its way into European commerce.

Description.—An opaque, grayish, sticky liquid of the consistency of thick honey, thinner and less opaque when heated, becoming thicker with age and exposure, separating on long standing a thick heavy dark-brown stratum which is transparent in thin layers; of a strong and pleasant balsamic odor, slightly resembling that of vanilla, and a pungently balsamic taste; burning with a bright sooty flame; soluble, excepting the water and other impurities, in alcohol, ether, chloroform, and most volatile oils; yielding, with an equal weight of warm alcohol, a gray-brown, turbid, acid solution which, after cooling, filtering, and evaporating, should leave not less than 70 per cent. of the weight of the styrax as a brown, semi-liquid mass which deposits crystals only after a long time, gives off a bitter almond odor when boiled with potassium bichromate and sulphuric acid, and, with the exception of a few floccules, is completely soluble in ether and in carbon disulphide; insoluble in cold petroleum benzin, but partly soluble in it when hot, the colorless solution depositing crystals of cinnamic acid and cinnamic ethers on cooling. Examined under the microscope, storax is seen to consist of minute globules, intermixed with larger drops of water and with tabular crystals of cinnamic acid, and when left on the object glass feathery crystals of styracin make their appearance. Hager proposed to detect the presence of turpentine by dissolving the storax in a little warm alcohol and exhausting it with petroleum benzin by agitation. On evaporating the benzin solution the residue should have a bluish opalescence and an agreeable odor, while if turpentine be present the color will be yellowish and the odor of turpentine will be apparent.

Constituents.—Storax is a variable mixture of resins, volatile oil, cinnamic acid and its esters, and water. In the commercial article water is sometimes present to the extent of 40 per cent. When distilled with water or steam under pressure, it yields from 0.5 to 1 per cent. of an aromatic oil, of pale-yellow to brown color, and varying in specific gravity from 0.890 to 1.10. The oil from Oriental storax shows an optical rotation of —3° to —38°, while that obtained from American storax is dextrorotatory, having a specific rotation of $[\alpha]_D = 16°33'$. Among the chemical constituents of storax is styrene (styrol, cinnamene, phenylethylene), having the composition C_8H_8 or C_6H_5-$CHCH_2$, a colorless, highly refractive liquid of pleasant odor, optically inactive and boiling, when pure, at 144° to 144.5° C. (291.2°–292.1° F.). Upon long keeping, in contact with acids, or when heated to 200° C. (392° F.), it is polymerized into metastyrene, a transparent, odorless, glass-like body. Cinnamic acid, $HC_9H_7O_2$ or $C_6H_5C.H.$-$CH.COOH$, is present in storax to the extent of 5 to 15 per cent. (23 per cent. Flückiger, Van Italie), chiefly in the free state, and may be extracted by treatment with sodium carbonate solution and subsequent precipitation with hydrochloric acid. There are also present styracin (cinnamyl or styryl cinnamate), $C_9H_9.C_9H_7O_2$, phenyl-propyl cinnamate, $C_6H_5C_3H_5.C_9H_7O_2$, ethyl cinnamate, $C_2H_5.C_9H_7O_2$, vanillin (K. Dieterich), ethylvanillin (von Miller), α and β storesinol, $C_{35}H_{55}(OH)_3$, two amorphous resins of alcoholic character which constitute a large part of the storax. Furthermore, traces of benzoic acid and storesinol cinnamic acid ester have been found. American storax is said not to contain ethyl cinnamate.

Storax of good quality should not contain over 30 per cent. of water, and at least 60 per cent. of its weight should be soluble in alcohol. When dried and incinerated not more than 1 per cent. of ash should be left. Its acid value, ascertained as explained below, should be not less than 55 to 75, its saponification value (see below) 100 to 140, and its ester value, obtained by subtracting the acid value from the saponification value, should be from 35 to 75.

K. Dieterich (*Analyse der Harze, Balsame*, etc., 1900) suggests the following methods for examination of storax:

For determination of the acid value, 1 Gm. of storax is dissolved in 100 Cc. of 96 per cent. alcohol and then titrated with half-normal alcoholic potassium hydroxide solution, using phenolphthalein as indicator. The number of cubic centimeters of alkali solution neutralized, if multiplied by 28.08, will express the acid value. For determination of the saponification value, 1 Gm. of storax is put into a glass-stoppered 250-Cc.

flask, together with 20 Cc. of half-normal alcoholic potassium hydroxide solution and 50 Cc. of benzin of 0.700 specific gravity, and allowed to stand at ordinary room temperature for 24 hours, after which the excess of alkali is titrated with half-normal sulphuric acid, using phenolphthalein as indicator. The number of cubic centimeters of alkali required for saponification, if multiplied by 28.08, will express the saponification value.

Since storax cannot be weighed conveniently, it is rarely possible to weigh exactly 1 Gm. for the above operation, and hence a slight correction must be made when more or less than 1 Gm. of the material is used. Thus, if 1.108 Gm. of storax was used and required 5.57 Cc. of the half-normal alkali solution, then $1.108 : 5.57 :: 1 : x$, and, the value of x having been found equal to 5.027+, the volume of alkali solution necessary for 1 Gm. would correspond to 5.03 Cc., the number in this case to be multiplied by 28.08.

A sample adulterated with tar, which had remained for some time in a glass-stoppered bottle in the Museum of the New York Botanical Garden, imparted to the stopper a fine storax odor, while that of the contents of the bottle was strongly tarry.

Pharmaceutical Preparation.—Compound Tincture of Benzoin, U. S. P.

Action and Uses.—Storax, like copaiba, is a stimulant to nearly all mucous membranes. Although rarely employed, it may be given internally with good effect in the treatment of chronic catarrhs of the lungs and in chronic affections of the genito-urinary organs, as gonorrhœa and atonic amenorrhœa. Combined with 2 or 3 parts of olive oil it forms an efficient parasiticide for scabies; one application followed in a few hours by a bath will usually effect a cure. The dose of storax is from 10 to 20 grains (0.60–1.30 Gm.).

Allied Products.—Cortex Thymiamatis.—This is the bark from which storax has been obtained. It is in brown foliaceous cakes, consisting of thin pieces of bark and having the odor of storax.

Styrax Calamita.—This consists of sawdust mixed with liquid storax, and contains numerous minute crystals of styracin. The drug known by this name in ancient times and during the last century was a solid balsamic resin, most likely obtained from *Styrax officinale* L., which is indigenous to Western Asia and Southeastern Europe. This is no longer an article of commerce.

Liquidamber, or Sweet Gum, is a very similar balsam obtained from *Liquidamber styraciflua* L. (*Sweet*, *Red*, or *Star-leaved Gum-tree*, *Alligator*, *Opossum*, or *Copalm tree*, *Bilsted* or *Satin walnut*), as an exudation resulting from incisions through the bark. The tree grows from Connecticut to Illinois, southward and southwestward into Mexico, but the exudation is collected only in the south. The tree grows to a height of 40 to 60 feet and has widely spreading branches. The trunk-bark is dark gray and deeply fissured, that of the small branches mostly winged with corky projections. The leaves are dark green, round in outline, palmately 5- to 7-lobed, and the lobes serrate. The fruit is capsular, beaked, aggregated in globular heads, together with the indurated scales. The leaves, fruit, and bark, when bruised, have an agreeable odor; the taste of the bark is balsamic and astringent, and that of the other parts mentioned aromatic and acidulous. The balsam, also called *gum wax* (*Balsamo de liquidámbar*, Sp.), exudes in the form of a thick liquid, having the density of syrup and a yellowish color. On standing it thickens, becomes darker in color, and finally hard at the ordinary temperature, and breaks with a resinous fracture, which is of a variegated appearance, the color being brown, with lighter (and even white) spots and streaks. It softens somewhat by the warmth of the hand, and when heated fuses to a yellowish-brown liquid. It has a very pleasant balsamic odor and taste, the latter being followed by pungency. It dissolves completely—fragments of bark excepted—in alcohol, ether, and chloroform, the alcoholic solution having a slight acid reaction.

The composition of sweet gum is closely similar to that of styrax. Harrison found in it 3.5 per cent. of a substance resembling styrene, but not convertible into metastyrene, 5.5 per cent. of cinnamic acid, styracin, a nearly odorless and tasteless dark-brown resin, and 9 per cent. of impurities.

SUCCI.—Juices.

Sucs végétaux, Fr.; *Pflanzensäfte*, G.

These preparations are made by bruising the fresh drugs, expressing them forcibly, and mixing the expressed juice, with a definite proportion of alcohol for preservation. They must necessarily vary in the amount of their active constituents, and perhaps more so than the dried and carefully-preserved drugs. They have been dismissed from the U. S. P., and tinctures of fresh herbs admitted in place thereof.

SUCCUS BELLADONNÆ, *Br.*—Juice of Belladonna.

Suc de belladone, Fr.; *Belladonnasaft*, G.

Preparation.—Bruise fresh leaves and young branches of Atropa Belladonna L., press out the juice, and to every 3 volumes of juice add 1 of alcohol (90 per cent.). Set aside for 7 days, and filter.—Br.

Action and Uses.—This preparation is given in the dose of 5 to 15 minims (0.30–1 Cc.). (See BELLADONNA.)

SUCCUS CONII, *Br.*—Juice of Conium.

Juice of hemlock, E.; *Suc de grande ciguë*, Fr.; *Schierlingsaft*, G.

Preparation.—Bruise the fresh leaves and young branches of Conium maculatum, L., press out the juice, and to every 3 volumes of juice add one of alcohol (90 per cent.). Set aside for 7 days, and filter.—Br.

Action and Uses.—Because of its uncertain strength this is an unsatisfactory preparation of conium to employ. Its dose, usually stated to be from ½ to 1 drachm (2–4 Cc.), has been found to be too small, and must be rapidly increased to produce the desired effect.

SUCCUS HYOSCYAMI, *Br.*—Juice of Hyoscyamus.

Suc de jusquiame, Fr.; *Bilsenkrautsaft*, G.

Preparation.—Bruise fresh leaves, flowering tops, and young branches of Hyoscyamus niger, L., press out the juice, and to every 3 volumes of juice add 1 of alcohol (90 per cent.). Set aside for 7 days, and filter.—Br.

Action and Uses.—The dose of this juice is from ½ to 1 drachm (2–4 Cc.).

SUCCUS SCOPARII, *Br.*—Juice of Broom.

Suc de genêt à balais, Fr.; *Besenginstersaft*, G.

Preparation.—Bruise fresh broom-tops, press out the juice, and to every 3 volumes of juice add 1 of alcohol (90 per cent.). Set aside for 7 days, and filter.—Br.

Action and Uses.—This preparation represents the properties of scoparius. It is given in the dose of 1 to 2 drachms (4–8 Cc.).

SUCCUS TARAXACI, *Br.*—Juice of Dandelion.

Suc de pissenlit, Fr.; *Löwenzahnsaft*, G.

Preparation.—Bruise fresh taraxacum-root, press out the juice, and to every 3 volumes of juice add 1 of alcohol (90 per cent.). Set aside for 7 days, and filter.—Br.

Action and Uses.—This is an efficient preparation of taraxacum. The dose is from 2 to 4 drachms (8–16 Cc.).

SULPHONETHYLMETHANUM, *U. S.*—Sulphonethylmethane.

Trional, Fr. Cod.; *Methylsulfonalum*, P. G.; *Trionalum.—Trional, Diethylsulphonemethylethylmethane*, E.; *Diéthylsulfone-méthyléthylméthane*, Fr.; *Methylsulfonal, Trional*, G.

Formula, $C_8H_{18}S_2O_4$ or $(CH_3)(C_2H_5)C(SO_2C_2H_5)_2$. Molecular weight, 240.46.

Diethylsulphonemethylethylmethane is a product of the oxidation of the mercaptol obtained by the condensation of methylethylketone with ethylmercaptan. It should be preserved in well-stoppered vials.—U. S. The commercial name, trional, by which this compound is better known, was adopted on account of the 3 ethyl groups present.

Preparation.—Sulphonethylmethane is usually prepared on a large scale by saturating a mixture of ethylmercaptan and methylethylketone with hydrochloric acid gas, and oxidizing the resulting condensation product $(CH_3)(C_2H_5)C(SC_2H_5)_2$, known as methylethylketonemercaptol, by means of a weak potassium permanganate solution. The resulting compound is purified by frequent recrystallization from boiling water.

Properties and Tests.—Sulphonethylmethane occurs as colorless, lustrous, odorless, crystalline scales, which have a bitter taste in aqueous solution. It is soluble in

195 parts of water at 25° C. (77° F.), more readily in boiling water, and readily soluble in alcohol and ether. When heated to 76° C. (168.8° F.), it melts, and at a red heat is consumed, evolving sulphur dioxide and leaving no weighable residue. Its aqueous solution is neutral to litmus-paper. If 0.1 Gm. of sulphonethylmethane be heated with 0.1 Gm. of powdered charcoal in a dry test-tube, the characteristic unpleasant odor of mercaptan will be developed. If 0.1 Gm. be gradually heated with dried sodium acetate, hydrogen sulphide will be evolved. 1 Gm. dissolved in 50 Cc. of boiling water should develop no odor. This solution, when cooled and filtered, should show no turbidity on the addition of barium nitrate test-solution or silver nitrate test-solution (absence of sulphates and chlorides). One drop of potassium permanganate test-solution, added to the aqueous solution of sulphonethylmethane should not be immediately decolorized (absence of readily oxidizable organic impurities).—U. S.

The French and German Pharmacopœias both give the solubility of trional in cold water as 1 part in 320 parts.

Action and Uses.—Sulphonethylmethane or trional closely resembles sulphonal in its action. It differs in the time required to produce sleep, being effective usually in 20 to 30 minutes. Its dose is from 15 to 30 grains (1–2 Gm.), and its method of administration like that of sulphonal.

SULPHONMETHANUM, *U. S.*—Sulphonmethane.

Sulphonal, Br.; *Acétone-diéthylsulfone*, Fr. Cod.; *Sulfonalum*, P. G.—*Sulphonal, Diethylsulphone-dimethylmethane*, E.; *Sulfonal, Diéthylsulfone-diméthylméthane*, Fr.; *Sulfonal*, G.

Formula, $C_7H_{16}S_2O_4$ or $(CH_3)_2C(SO_2C_2H_5)_2$. Molecular weight, 226.55.

Diethylsulphonedimethylmethane is a product of the oxidation of the mercaptol obtained by the condensation of acetone with ethylmercaptan. It should be preserved in well-stoppered vials.—U. S.

Preparation.—When dry hydrochloric acid gas is led into a mixture of 2 parts of anhydrous ethyl hydrosulphide (mercaptan, C_2H_5SH) and 1 part of anhydrous acetone, heat is slowly developed; the mixture becomes gradually turbid, and finally separates into two distinct layers, the lower being a dilute hydrochloric acid, while the upper is composed of a new compound, known as dithioethyldimethylmethane or acetone mercaptol $(CH_3)_2C(SC_2H_5)_2$, a condensation-product of the interaction between the mercaptan and acetone. Mercaptol may also be obtained by a process patented in Germany, which consists in first treating sodium thiosulphate with ethyl chloride or bromide, whereby sodium ethylthiosulphate is produced; thus, $Na_2S_2O_3 + C_2H_5Cl = NaC_2H_5S_2O_3 + NaCl$: this salt in the presence of water yields acid sodium sulphate and ethyl hydrosulphide or mercaptan; the latter is not separated, but in its nascent state, in the presence of hydrochloric acid, is allowed to react with acetone, condensing to mercaptol. Obtained by either process, mercaptol is an oily liquid, which is purified by washing with water and afterward with dilute soda solution; it is dried by means of calcium chloride and rectified by distillation; it boils at 190°–191° C. (374°–375.8° F.), is highly refractive, insoluble in water, and has a very disagreeable odor. Upon agitating mercaptol with 5 per cent. potassium permanganate solution until the color of the latter remains, oxidation takes place and the mercaptol is converted into sulphonal; thus, $(CH_3)_2C(SC_2H_5)_2 + O_4 = (CH_3)_2C(SO_2C_2H_5)_2$. Sulphonal may be obtained absolutly pure by recrystallization from water or alcohol.

Properties and Tests.—Sulphonmethane occurs in colorless, inodorous, and nearly tasteless prismatic crystals. It is soluble in 360 parts of water, 47 parts of alcohol, 45 parts of ether, and in 16 parts of chloroform at 25° C. (77° F.); soluble in 15 parts of boiling water, and in 2 parts of boiling alcohol; soluble in benzene. When heated to 125.5° C. (258° F.) it melts, and at a red heat it is consumed, evolving vapors of sulphur dioxide, and leaving no weighable residue. Its aqueous solution is neutral to litmus paper. If 0.1 Gm. of sulphonmethane be heated with 0.1 Gm. of powdered charcoal in a dry test-tube, the characteristic unpleasant odor of mercaptan will be developed. If 0.1 Gm. be gradually heated with dry sodium acetate, hydrogen sulphide will be evolved. Its solution in boiling water should develop no odor. This solution, after cooling and filtering, should show no turbidity upon the addition of either barium nitrate test-solution or silver nitrate test-solution (absence of sulphates and chlorides).

If 1 drop of potassium permanganate test-solution be added to an aqueous solution of sulphonmethane, the liquid should not be immediately decolorized (absence of readily oxidizable organic impurities).—U. S.

Sulphonal is also soluble in 500 parts (P. G.) or 450 parts (Br.) of cold water, 65 parts (P. G.) or 50 parts (Br.) of cold alcohol; in 110 parts of 50 per cent. alcohol; in 11 parts of benzene; in 135 parts of ether; in about 1000 parts of petroleum ether, and to some extent in toluene and acetone. It dissolves in concentrated sulphuric acid, from which water reprecipitates the sulphonal undecomposed. It is a very stable compound, and not attacked by the mineral acids or boiling solutions of the alkalies, nor by oxidizing agents. If a few grains of sulphonal be mixed with an equal weight of potassium cyanide and heated, the odor of mercaptan is evolved, and when to the aqueous solution of the product an excess of hydrochloric acid and a few drops of solution of ferric chloride are added a red color is developed, due to the formation of ferric sulphocyanate (Br.). If a mixture of sulphonal and 3 parts of powdered potassium hydroxide be fused it becomes yellow, then red, and on dilution with water a blue color results, which, upon the addition of an excess of hydrochloric acid, turns a transient violet and sulphur is separated (Vitalli). It is best distinguished from trional and tetronal by its higher melting point and its crystalline form.

Action and Uses.—In the lower animals moderate doses of sulphonal produce sleep and a disturbance in muscular coördination. Large doses cause coma, convulsions, and paresis. It exercises its dominant influence upon the brain, only mildly affecting the peripheral nervous system.

Upon the circulation its effect is slight, and only in large quantities does it depress the respiratory function. When toxic doses are given, death results from paralysis of respiration. Most investigators agree with Kast, who maintains that sulphonal does not cause corpuscular changes in the blood. It is devoid of analgesic and anæsthetic properties. In man sulphonal produces sleep, from which the individual awakes usually refreshed, although mental dulness and bodily sluggishness are apt to follow.

Because of its slow solubility its effect is gradual, 2 to 4 hours elapsing before it is fully developed. Sulphonal may sometimes cause nausea, vomiting, diarrhœa, headache, vertigo, aphasia, hallucinations, tremors, paresis, an unsteady gait resembling that of locomotor ataxia, erythematous eruptions, etc. These symptoms are more apt to occur when the drug is taken for a long period of time than after a single full dose.

Its continuous use will derange digestion and impair the function of the kidneys, the urine becoming scant or entirely arrested and assuming a dark reddish hue from the presence of an unusual substance, hæmatoporphyrine. Any discoloration of the urine, therefore, should be looked upon as a signal to discontinue the use of the drug.

Sulphonal is employed as a hypnotic in insomnia due to functional derangement of the nervous system, and is valueless when pain or advanced disease is the cause of the wakefulness. It is an efficient soporific in cases of insanity characterized by great mental excitement, and has a quieting effect in delirium tremens, but is of little benefit in the delirium of acute febrile diseases.

As a hypnotic sulphonal is intermediate between chloral and paraldehyde, being, perhaps, less powerful than the former and more active than the latter. It is safer than most drugs of its class because it does not depress the heart. Comparatively few deaths from its employment are reported. As much as 120 grains (8 Gm.) have been taken, however, without ill effect, and Neisser has reported one case which recovered after taking about 3 ounces (90 Gm.).

To procure the best results from sulphonal certain peculiarities of its properties must be regarded. Being so slowly absorbed it should be administered from 2 to 4 hours before its effect is desired, and because of its relative insolubility in cold water it should be dissolved in hot water or hot milk and the solution swallowed as soon as it has cooled sufficiently to be drunk. It may be given in fine powder, in capsule or cachet, or suspended in mucilage or syrup. The dose of sulphonal is from 20 to 40 grains (1.30–2.60 Gm.).

Allied Products.—Methonal or Dimethylsulphonedimethylmethane $(CH_3)_2.C(SO_2CH_3)_2$.—This compound, occurring in colorless crystals, is prepared in a manner analogous to that given above for sulphonal, except that methyl hydrosulphide or methylmercaptan is used in place of ethyl hydrosulphide. It has been used as an hypnotic in the same dose as sulphonal.

TETRONAL or DIETHYLSULPHONEDIETHYLMETHANE $(C_2H_5)_2.C(SO_2C_2A_5)_2$.—The name tetronal was given to this compound on account of the 4 ethyl groups present. If diethylketone be used in place of acetone in the process given for the preparation of sulphonal, diethylketonemercaptol will be obtained, which, upon oxidation with potassium permanganate, yields tetronal, a compound analogous to sulphonal, trional, etc. It requires about 450 parts of cold water for solution, but less hot water, and is readily soluble in alcohol. It melts at 85° C. (185° F.). Its action is allied to that of sulphonal. It is given in the dose of 15 to 30 grains (1–2 Gm.).

SULPHUR, *U. S., Br., P. G.*—Sulphur.

Soufre, Fr.; *Schwefel*, G.

Symbol, S. Atomicity, bivalent, quadrivalent, and sexivalent. Atomic weight, 31.83.

Official Forms of Sulphur.—1. SULPHUR LOTUM, U. S.; *Sulfur depuratum*, P. G.—*Washed sulphur*, E.; *Soufre lavé*, Fr.; *Gereinigter Schwefel*, G.

2. SULPHUR (SULFUR) PRÆCIPITATUM, U. S., Br., P. G.; *Lac (Magisterium) sulphuris.*—*Precipitated sulphur, Milk of sulphur*, E.; *Soufre précipité, Magistère (Lait) de soufre*, Fr.; *Schwefelmilch*, G.

3. SULPHUR (SULFUR) SUBLIMATUM, U. S., Br., P. G.; *Flores sulphuris.*—*Sublimed sulphur, Flowers of sulphur*, E.; *Soufre sublimé, Fleur (Crême) de soufre*, Fr.; *Schwefelblumen, Schwefelblüthe*, G.—Sulphur sublimed and condensed to powder.

Washed and precipitated sulphur should contain not less than 99.5 per cent., and sublimed sulphur not less than 99 per cent. of pure sulphur.—U. S.

Origin.—Sulphur occurs most abundantly in the native state in volcanic countries. Beds of native sulphur have been discovered in California, Nevada, Utah, and other parts of the Western United States, in Mexico, the West Indies, etc.; the chief supply of sulphur, however, comes from Italy, where extensive beds are worked near Latera and Scrofano, and from the provinces of Girgenti, Caltanisetta, Catania, and Palermo in the island of Sicily, where nearly 100,000 tons are obtained yearly. Sulphur-beds on the surface of the earth are called *solfatare*, and when they are found underground are known as *solfare*. The latter are the most important, and yield nearly the whole of the commercial sulphur. It is found in many mineral waters as hydrogen sulphide and in the form of sulphates, and is widely distributed in the mineral kingdom in combination with metals, forming iron pyrites, FeS_2, galena, PbS, blende, ZnS, black antimony, Sb_2S_3, cinnabar, HgS, and other sulphides, and as sulphate in gypsum, heavy spar, and many other minerals. Sulphur is a constituent of the volatile oils of mustard, garlic, and asafetida, and of albumin and other proteids.

Sulphur in the free state is sometimes found in sedimentary rocks, occasionally in pure and well-formed crystals. Such deposits are due in great part to the activity of bacteria and algæ, which during life store up so much sulphur that it constitutes from 10 to 25 per cent. of the weight of the living cells. The Beggiatoa bacteria especially have the peculiar power of converting hydrogen sulphide, which arises from gypsum during fermentation of cellulose, into sulphuric acid, during which process, however, a great portion of the sulphur is stored up in the cells in granules as a future food supply.

Extraction and Purification.—Sulphur is obtained in Sicily by melting it from the mineral in semicircular pits called *calcaroni*, which have a diameter of about 30 feet and a depth of about 8 feet, and are internally covered with a layer of gypsum. The bottom is inclined toward one side, which has an opening, closed during the operation with a thin wall of gypsum. The pit is filled with the mineral, and this is heaped up above so as to form an obtuse cone, the whole being covered first with a layer of powdered sulphur ore, and finally with a stratum of spent ore in powder. Fire is now applied to the heap, and after an hour all openings are closed until, after about nine days, the melted sulphur begins to collect on the floor of the pit. Through a small opening made into the gypsum wall the melted sulphur is removed two or three times a day and run into moistened moulds made of poplar wood, where it solidifies in the form of blunt pyramids, in which condition it enters commerce. The *rough sulphur* thus obtained contains from 3 to 4 parts of earthy impurities, which are removed by distilling the sulphur from iron retorts and conducting the vapors into large brick chambers, where they condense in the form of a fine powder, which is from time to time removed before the condensing-chamber becomes too hot, and constitutes *sublimed sulphur*. If,

however, the operation is not interrupted, the brick walls of the chamber become hot enough to melt the sulphur, which is run into wooden moulds. The cylindrical pieces thus obtained enter commerce as *brimstone* or *roll sulphur.*

In Nevada the sulphur ore is placed in upright cast-iron retorts, in shape resembling a blast-furnace; superheated steam is admitted and the pressure raised to about 70 pounds to the square inch; the pressure is slowly reduced to 50 pounds as the melted sulphur flows through a grate into a receiving-pan, where mechanical impurities are allowed to subside, the sulphur being run into large cylindrical moulds, and after cooling broken into irregular lumps before it is refined.

Sulphur is also obtained from pyrites by a process of roasting in heaps or in suitable furnaces built for the purpose, a portion of the sulphur being burned in the operation.

Preparation.—Sublimed Sulphur. The process by which this is procured has been described above. The other official forms of sulphur are prepared as follows:

Washed Sulphur. Sublimed sulphur, 100 Gm.; ammonia water, 10 Cc.; water, a sufficient quantity. Pass the sublimed sulphur through a No. 30 sieve, mix it thoroughly with 100 Cc. of water, add 10 Cc. of ammonia water, and digest for three days, agitating occasionally. Then add 100 Cc. of water, transfer the mixture to a muslin strainer, and wash the sulphur with water until the washings cease to impart a blue color to red litmus-paper. Then allow it to drain, press the residue strongly, dry it rapidly at a moderate heat, and pass it through a No. 30 sieve.—U. S. The P. G. orders for 10 parts of sublimed sulphur 7 parts of water and 1 part of ammonia water, the mixture to be macerated for a day. Prolonged digestion is unnecessary for the removal of the free acid, but it is important that after thorough washing the sulphur be well dried to prevent its slow oxidation.

Precipitated Sulphur. Sublimed sulphur, 100 Gm.; lime, 50 Gm.; hydrochloric acid, water, each a sufficient quantity. Slake the lime, and make it into a uniform mixture with 500 Cc. of water. Add the sulphur, previously sifted, mix well, add 1000 Cc. of water, and heat the mixture to boiling for one hour, stirring constantly and replacing the water lost by evaporation. Then cover the vessel, allow the contents to cool, pour off the clear solution, filter the remainder, and to the united liquids add, gradually, with constant stirring, hydrochloric acid previously diluted with an equal volume of water, until the liquid is nearly neutralized, still retaining, however, an alkaline reaction and a yellow color. Collect the precipitate on a strainer, and wash it with water until the washings are tasteless and cease to give a precipitate with ammonium oxalate test-solution. Then dry it rapidly with a gentle heat, and keep in well-stoppered bottles.—U. S.

In the process described, calcium thiosulphate and pentasulphide are formed in solution, thus: $3Ca(OH)_2 + 12S. = CaS_2O_3 + 2CaS_5 + 3H_2O$. Theoretically 50 parts of quicklime or slaked lime require 115 or 87 parts of sulphur respectively. It is, however, advisable to employ an excess of sulphur, the undissolved portion of which may be used in a subsequent operation. The resulting liquor has a dark orange-red color. Diluted hydrochloric acid should now be added in a thin stream and with continued stirring, when the calcium pentasulphide will be decomposed, calcium chloride remaining in solution, while sulphur is precipitated and hydrogen sulphide is liberated, which should be carried off through a chimney. This reaction occurs according to the equation $2CaS_5 + 4HCl = 2CaCl_2 + 4S_2 + 2H_2S$. If the acid be added with the precaution that the liquid retains its alkaline reaction, calcium hydrosulphide, $Ca(HS)_2$, will remain in solution, and with it any arsenic which may have been present in the sulphur or in the acid; but in the presence of iron black ferrous sulphide will be precipitated with the sulphur, and impart to it a dark-gray color. The latter impurity may be easily removed by washing first with water, followed by dilute hydrochloric acid, and this again by water.

Operating in this manner, as directed by the U. S. P., the calcium thiosulphate will not be decomposed. The further addition of acid will decompose this compound, sulphur being liberated, together with sulphur dioxide, and the latter, by reacting with the hydrogen sulphide, will liberate an additional quantity of sulphur, with the formation of water. The result of the entire complicated reaction is expressed by the equation $2CaS_5 + CaS_2O_3 + 6HCl = 6S_2 + 3CaCl_2 + 3H_2O$. It will be observed that by acidulating the solution of lime and sulphur, as directed by the British Pharmacopœia, a larger amount of precipitated sulphur is obtained; but it was shown by Fordos and Gélis (1851),

and by Berthelot, that that resulting from the thiosulphate is soft and only partially soluble in carbon disulphide. Arsenic, if present in the lime solution, will separate as yellow arsenic sulphide.

Properties.—Sulphur exists in several modifications, and is either crystalline and soluble in carbon disulphide, or amorphous and insoluble in the same liquid. At least six crystallized modifications of sulphur are known, but only two forms are easily obtained—namely, the rhombic and the monoclinic. Rhombic crystals, melting-point 114° C. (237.2° F.), are obtained from solutions of sulphur at ordinary temperature, while monoclinic crystals, melting-point 118° C. (248° F.), result from hot solutions and when molten sulphur cools. The latter crystals readily change to the former. When molten sulphur at a high temperature is suddenly cooled it becomes amorphous and plastic, and is characterized by its softness, insolubility, and low specific gravity (1.957 instead of 2.045). Amorphous sulphur is present in precipitated sulphur in finely divided form, and also in sublimed sulphur. When the latter is shaken with carbon disulphide, about one-third remains undissolved and is amorphous. On gradually heating to near 180° C. (356° F.) sulphur becomes brown, and ultimately black, opaque, and very viscid. If the heat be continued, the mass liquefies again at 260° C. (500° F.), and at about 450° C. (842° F.) is converted into orange-brown vapors. Heated in the air, sulphur ignites at about 150° C. (302° F.), and burns with a blue flame to sulphurous anhydride or sulphur dioxide, SO_2. This gas always contains a small quantity of the trioxide or sulphuric anhydride, SO_3, according to Lunge and Salathé (1883), if the combustion takes place in dry air, the amount being 2.5 or 2.8 per cent., and the quantity being increased in the presence of ferric oxide. The two oxides named are the only oxygen compounds which have been obtained in the isolated state, though several others are known in combination, of which the most important is thiosulphuric acid. (See Sodii Thiosulphas.) The other oxygen compounds of sulphur are as yet only of scientific interest: they are hyposulphurous (also called hydrosulphurous) ($H_2S_2O_4$), dithionic, trithionic, tetrathionic, and pentathionic acids, having the composition $H_2S_2O_6$, $H_2S_3O_6$, $H_2S_4O_6$ and $H_2S_5O_6$ respectively. These four acids, when liberated from their salts, are readily decomposed into sulphuric and sulphurous acids, the last three separating also sulphur. In recent years salts of another oxygen acid of sulphur have been prepared—namely, the persulphates, as $K_2S_2O_8$, which are excellent oxidizers. (See under Acida and also Potassium.)

Sulphur combines also with most of the non-metallic and metallic elements, forming sulphides, the most important of which to the pharmacist are the sulphides of antimony, mercury, iron, potassium, ammonium, and hydrogen. When treated at an elevated temperature with volatile and fixed oils, it dissolves, and forms with the fats compounds which were formerly known as balsams of sulphur. Sulphur is insoluble in water, but dissolves in hot solutions of the fixed alkalies and alkaline earths, forming sulphides, and is somewhat soluble in hot absolute alcohol, ether, chloroform, oil of turpentine, benzin, and benzene, being deposited on cooling in crystals. Carbon disulphide promptly dissolves a portion of it, but leaves a residue of insoluble sulphur, which may be dissolved by a boiling solution of alkali hydroxide.

Sublimed sulphur is a yellow or somewhat greenish-yellow, slightly gritty powder, which is free from odor and taste, or generally has a slight sulphurous odor and a faint acidulous taste, and has a slight acid reaction to litmus. To heat and solvents it shows the behavior described above.

Washed sulphur has the same appearance and behavior as the preceding, except that it is entirely inodorous and nearly tasteless, and does not change the color of litmus-paper, which properties are demanded by the Br. P. for its sulphur sublimatum, but which cannot be met. (E. Merck, *Chemist and Druggist*, 1898, p. 349.)

Precipitated sulphur is a yellowish-white or grayish, very fine powder, free from grittiness and from the odor of hydrogen sulphide, and nearly tasteless. When examined under the microscope it is seen to consist of opaque globules which are free from crystalline matter. It is not altered on exposure to air when kept dry, and on fusion it is converted into ordinary sulphur.

Tests.—Water agitated with washed or precipitated sulphur (U. S.), or these varieties of sulphur moistened with water (P. G.), should not redden blue litmus-paper; the latter is the more delicate test. Pure sulphur should completely evaporate by heat, and when ignited in the air should burn without leaving any fixed residue (clay, gypsum, etc.). The pharmacopœias permit a trace (0.1 to 1 per cent.) of fixed residue for sub-

limed (0.5, U. S.) and washed (0.2, U. S.), but none for precipitated, sulphur. The latter, if precipitated by sulphuric acid, is more readily miscible with water than pure precipitated sulphur, and leaves on ignition a large amount of fixed residue. For the detection of this and other fixed impurities the following additional but unnecessary tests may be employed: If precipitated sulphur be boiled with diluted hydrochloric acid, the liquid filtered, and the filtrate divided into two portions, one portion should not be precipitated by test-solution of barium chloride, and the other portion should not be rendered more than slightly turbid by test-solution of ammonium carbonate with excess of ammonia-water (absence of calcium sulphate). When digested successively with water, hydrochloric acid, and ammonia water, these liquids, after filtration, should leave no residue on evaporation (absence of alkalies, alkaline earths, or sulphide). Sulphur obtained from pyrites usually contains arsenic, which is most conveniently detected, unless present in very minute quantities, by digesting it with 20 parts (P. G.) of ammonia water, filtering, and adding hydrochloric acid, when yellow arsenic sulphide will be precipitated; on the further addition of hydrogen sulphide, arsenous acid, if present, will yield a yellow precipitate of arsenic sulphide. While arsenous acid may be present in sublimed and in washed sulphur, it is obvious from the above explanation of the process that precipitated sulphur may be contaminated with the sulphide, but not with the oxide of arsenic. Very minute quantities of this metal are detected thus: If 0.5 Gm. of washed or precipitated sulphur be digested for several hours with 10 Cc. of ammonia water, the clear filtered liquid evaporated to dryness on a water-bath, then, after adding 1 Cc. of nitric acid and again evaporating, the solution of the residue in 10 Cc. of hydrochloric acid (8 per cent.) should not respond to the modified Gutzeit's test for arsenic (given under ARSENI TRIOXIDUM).—U. S. Selenium, which is sometimes present in sulphur, is detected by boiling 0.5 Gm. of the sample with a solution of 0.5 Gm. of potassium cyanide in 5 Cc. of water, and, if after filtration, the clear liquid be acidulated with hydrochloric acid, it should not assume a reddish color, even after standing an hour (absence of selenium). Precipitated sulphur frequently has a slight odor of hydrogen sulphide, which is more apparent on being warmed; such sulphur acquires a more or less black color when agitated with a solution of lead acetate; the pharmacopœias give no chemical test, almost complete freedom from odor being sufficient.

Action and Uses.—Sulphur has little influence over the general system. Given internally it is absorbed into the blood to some extent, eliminated in the perspiration, milk, urine, etc., and exercises a gentle alterative effect upon the skin and mucous membranes. In the small bowel it undergoes chemical changes resulting in the formation of hydrogen sulphide, to which is due the unpleasant flatus following its use.

It is a mild stimulant to intestinal secretion and acts as a gentle laxative, producing soft, mushy stools. The germicidal properties of sulphur are due to the sulphurous acid gas and sulphides formed from its decomposition. As a laxative, sulphur is of especial value to soften the stools and correct the constipation which occurs in stricture of the bowels, hemorrhoids, and anal fissure.

A combination of sulphur, cream of tartar, and molasses is extensively employed in domestic medicine as a laxative and "blood purifier."

In the treatment of chronic rheumatism, gout, and sciatica sulphur was at one time a highly esteemed remedy, but is rarely employed at present. It was given internally and applied locally in powder, ointment, or bath. Some cases of chronic bronchitis with excessive secretion are greatly benefited by 5 to 10 grains (0.30–0.60 Gm.) of sulphur given 3 times a day.

The most important use of sulphur is in the treatment of various skin diseases. For this purpose it is applied usually in ointment made preferably with precipitated sulphur because of its fine state of comminution. It is a specific in scabies and is beneficial in inveterate cases of acne, eczema, psoriasis, tinea versicolor, and other eruptions when a stimulating application is indicated.

When used in scabies it is important that the skin be thoroughly softened by soaking in hot water and the epidermis removed by brisk rubbing with a rough towel before the ointment is applied. This procedure exposes the female parasite which burrows beneath the skin to the action of the sulphur. The ointment should be allowed to remain on the part all night and be used for 3 or 4 nights consecutively.

Before the advent of formaldehyde the fumes of burning sulphur were extensively employed to disinfect sick rooms from which cases of contagious diseases had been

removed. It is disadvantageous because it destroys the colors of the wall paper, hangings, etc. Sulphur is given in the dose of 1 to 2 drachms (4–8 Gm.) as a laxative, and from 10 to 20 (0.60–1.30 Gm.) as an alterative. For internal use washed sulphur is preferable because it is free from acids to which the griping is due.

SULPHURIS IODIDUM, *U. S., Br.*—Sulphur Iodide.

Sulfur iodatum, Iduretum sulfuris.—Iodure de soufre, Fr.; *Jodschwefel*, G.

Preparation.—Washed sulphur, 20 Gm.; Iodine, 80 Gm. Mix the sulphur and iodine thoroughly by trituration; introduce the mixture into a flask, close the orifice loosely, and by means of a water-bath gradually and with occasional agitation apply a heat not exceeding 60° C. (140° F.) until the ingredients combine, which is indicated by the color becoming uniformly dark throughout the mixture. Then increase the heat to the boiling-point of the water, so as to fuse the mass. By inclining the flask unite any iodine which may have sublimed and condensed on the sides of the flask with the fused mass, and then pour the latter upon a porcelain plate or other suitable cold surface. After cooling, break the product into pieces of suitable size, and keep them in a glass-stoppered bottle in a cool place.—U. S., Br.

Although many consider the substance thus obtained a definite compound with the composition S_2I_2, it lacks entirely the chemical characteristics which analogy with the chloride and bromide of sulphur indicates would be possessed by a true iodide. As far back as 1813 Gay-Lussac stated that any union between the elements must be of a most feeble kind. The melting-point of the substance is 66° C. (150.8° F.), which is much less than that of either constituent. This fact is the only strong point in favor of a chemical compound, while in all other respects the substance acts like a solution of one element in the other. The whole matter is thoroughly discussed by MacIvor in an article in *Chem. News*, vol. 86, p. 5, 1902, which concludes with the remark that the opinion of Sestini (1863) may not be so far from the truth, after all—namely, "there exist a great number of compounds of sulphur and iodine obtained by fusion and solution, all being analogous in character to metallic alloys."

Properties.—Sulphur iodide is a grayish-black mass of a radiated crystalline appearance and with a metallic lustre. It resembles iodine in smell and taste, and on exposure to the air gradually loses iodine. If exposed to a gradually increased heat it sublimes, the first portion of the sublimate consisting of iodine, and the portion subsequently obtained containing sulphur; only a minute trace of fixed residue should be left. Sulphur iodide is insoluble in water, but dissolves in about 60 parts of glycerin, and is very soluble in carbon disulphide, on the spontaneous evaporation of which at a low temperature iodine crystallizes first, and afterward rhombic pyramids of *sulphuric iodide* are obtained, having the formula SI_6 (Vom Rath, 1860), and on exposure to the air leaving sulphur in the form of a delicate crystalline skeleton (Lamers, 1861). Alcohol, ether, volatile oils, and cold solutions of potassium hydroxide and of potassium iodide decompose sulphur iodide by dissolving the iodine. A similar decomposition is effected by boiling the sulphur iodide with water, with the vapors of which the iodine passes off, leaving a residue of sulphur amounting to 20 per cent. of the weight of the sulphur iodide employed; this is recommended as a test of purity by the U. S. P. and Br. P. If 0.5 Gm. of the finely powdered iodide and 1 Gm. of potassium iodide be dissolved in 20 Cc. of water (the sulphur separating), not less than 28 Cc. of tenth-normal sodium thiosulphate solution should be required for complete decolorization of the mixture.—U. S. Each Cc. of the thiosulphate solution represents 0.01259 Gm. of iodine; hence 28 Cc. represent 0.3525 of iodine, or 70.5 per cent.

Action and Uses.—Sulphur iodide has been used as an application in certain chronic skin lesions, as lupus and lepra. It was applied in ointment containing 1 to 3 parts to 10 of lard. According to the strength of the ointment employed it is either a stimulant or caustic.

SUMBUL, *U. S.*—Sumbul Root.

Sumbul radix, Br.—*Musk-root*, E.; *Sumbulwurzel, Moschuswurzel*, G.; *Racine de sumbul*, Fr.; *Sambulus*, Port.

The dried rhizome and roots of an unknown plant of the family *Umbelliferæ*.

Origin.—Accurate nomenclature would require that this article be called "False Sumbul," since the original and genuine Sumbul, with a strong odor of musk, whence

the common name, and which was the dried root of *Ferula Sumbul* Hook. f. (*Euryangium* S.—Kauffm.; *Sumbulus moschatus* Renisch.; *Angelica* m.—Wiggers.—Fam. *Umbelliferæ*), native of Turkestan, has not been imported for many years. The definition of the Pharmacopœia of 1890, naming the latter, did not therefore agree with its description, which was of the former. Holmes, who has grown and studied *F. Sumbul*, has shown clearly that the article at present so called is distinct and unknown, except by its drug, which enters commerce from central and western Asia through Moscow. The thick, annulate portions of the drug are apparently rhizome, but the small, smooth pieces more likely pertain to the roots.

Fig. 417.

Sumbul root (½ Nat.).

Description.—Occurring in very light and spongy transverse cylindrical sections from 0.5 to 12 Cm. (¼–5 In.) in diameter and 2.5 to 5 Cm. (1–2 In.) long; externally the larger pieces are dark brown, roughly wrinkled, and heavily annulate; the smaller successively less rough, some with a silvery-gray, nearly smooth cork, frequently exfoliating; internally yellowish white from the presence of yellowish resin-cells and fibro-vascular bundles distributed irregularly through the white parenchyma; fracture tough, irregular, somewhat starchy; odor strongly aromatic, slightly musky; taste characteristically aromatic, somewhat pungent and bitterish.

The brownish powder shows moderately numerous starch-grains, which are single or few or many united, mostly broadly oval, the hilum usually stellate, and numerous large, thin-walled resin-cells.

Constituents.—Nothing definite can be said to be known on this subject. Scarcely one of the contributions indicate which of the articles called sumbul were under examination. Probably Renisch's work (1843) was done with the original sumbul, and Utech's (1893) and Hahn's (1897) very fragmentary and superficial reports referred to that above described. Utech found more than 6 per cent. of the bitter resin which undoubtedly contained volatile oil, since it was markedly aromatic. It was nearly insoluble in ammonia-water, but soluble in ether, chloroform, and benzol. Hahn extracted with petroleum benzin more than 17 per cent. of a yellow, viscid fixed oil. The drug should not yield more than 6 per cent. of ash.

Pharmaceutical Preparations.—Extract of Sumbul, Fluidextract of Sumbul, U. S. P.

Action and Uses.—Sumbul possesses stimulant and antispasmodic properties similar to but milder than those of valerian. In combination with iron, arsenic, and similar drugs it is employed as a tonic in nervous exhaustion and various functional disorders of females, as hysteria, amenorrhœa, chlorosis, etc.

Its original application as a remedy in cholera, and atonic dysentery and diarrhœa is now rarely resorted to. A resin prepared from it has been found to relieve chronic mucous discharges from the lungs, urethra, and uterus. The dose of the root in powder is from 15 to 60 grains (1–4 Gm.). The fluidextract is given in the dose of 15 to 60 minims (1–4 Cc.), and the extract in the dose of 5 to 15 grains (0.30–1 Gm.).

Allied Products.—Several other roots have been called Sumbul. The genuine Sumbul was a fusiform vertical root, 12 to 25 Cm. (5–10 In.) long and 5 to 10 Cm. (2–4 In.) thick, which came in sections like those of the present false article, but less annulate. It was strongly musky. The East Indian *Jatamanshi Root*, or *Sumbul Hindi*, is from *Nardostachys Jatamansi* D. C. (Fam. *Valerianaceæ*). It is described as a rhizome, about ½ inch thick, of dark gray color, and bearing at the summit a tuft of reddish-brown fibres, the odor a mixture of valerian and patchouli. *Sumbul ekleti* or *ekelti*, *S. Kumi* or *S. Italicus*, is the rhizome of *Valeriana Celtica* L., of Europe. *Bombay Sumbul* or *Boi* is the root of *Dorema ammoniacum* Don. It has been used to adulterate Sumbul, and more nearly resembles the original than the modern drug.

SUPPOSITORIA, *U. S.*, *P. G.*—Suppositories.

Suppositoires, Fr. Cod.—*Suppositorien, Stuhlzäpfchen*, G.

Suppositories are solid bodies of various weights and shapes, adapted for introduction into the different orifices of the human body, and melting readily at blood heat. The

vehicles usually employed are oil of theobroma, glycerinated gelatin, or sodium stearate.—U. S.

The German Pharmacopœia designates oil of theobroma alone as the official vehicle for suppositories, while the French Codex permits them to be made with oil of theobroma, soap, or tallow, but directs the first-named vehicle in all of its official formulas. The British Pharmacopœia gives no general directions for making suppositories, but recognizes 7 official varieties, all of which, with one exception, are made with oil of theobroma.

Preparation.—For suppositories made with oil of theobroma the following general processes may be employed: Take of the medicinal substance the prescribed quantity; oil of theobroma, grated, a sufficient quantity. Reduce the medicinal substance, if dry, to a very fine powder, or, if an extract, soften it with an appropriate liquid, then mix it thoroughly in a mortar with about an equal weight of grated oil of theobroma, and incorporate the remainder of the oil of theobroma until a homogeneous, plastic mass is obtained, adding, if necessary, a small quantity of expressed oil of almond. Roll the mass on a graduated tile until a cylinder of the proper length is formed, divide this into the required number of equal parts, and with a spatula, or other convenient mechanical aid, form them into the desired shape. If the process of fusion is preferred, mix the medicinal substance with about an equal weight of grated oil of theobroma, as above directed, then thoroughly incorporate it with the remainder of the oil of theobroma, previously melted by a gentle heat, in a suitable vessel provided with a lip; then allow it to cool to about 38° C. (100.4° F.), and, when the mixture begins to congeal, pour it immediately into suitable well-cooled molds. Keep the molds at a freezing temperature until the suppositories have hardened and are ready to be removed. For suppositories containing chloral, phenol, their derivatives, or substances which soften the vehicle, raise the melting-point of the oil of theobroma by the addition of from 10 to 15 per cent. of spermaceti, but the melting-point must not be raised above 37° C. (98.6° F.).

For suppositories made with glycerinated gelatin the following process may be used: Take of the medicinal substance the prescribed quantity; glycerinated gelatin, glycerin, water, each a sufficient quantity. Mix the medicinal substance, if solid and soluble in water or glycerin, or if a miscible liquid, with a little water, and add sufficient glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted glycerinated gelatin, and pour it at once into suitable molds which have been greased with a small quantity of petrolatum. Cool the molds thoroughly before removing the suppositories. Molds for urethral suppositories should be warmed sufficiently before pouring the mass to facilitate the proper filling of the mold. Suppositories having a firmer consistence may be prepared by substituting mucilage of acacia for a portion of the water or glycerin. If the medicinal substance be insoluble in water or glycerin, thoroughly levigate it in a warm mortar with a sufficient quantity of glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted glycerinated gelatin, and pour it into suitable molds as above directed. With bulky powders about one-half of the glycerin may be replaced with water before levigation. Glycerinated gelatin suppositories should be protected against the effects of heat and moisture and dry air by keeping them in tightly closed containers in a cool place.

Rectal suppositories should be cone-shaped or spindle-shaped, and when made from oil of theobroma should weigh about 2 grammes.

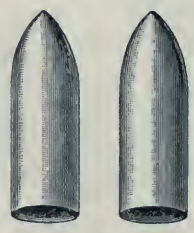
Urethral suppositories (bougies) should be pencil-shaped, pointed at one extremity, and either 7 centimeters in length, weighing about 2 grammes, or 14 centimeters in length, weighing about 4 grammes, when made with glycerinated gelatin. If prepared with oil of theobroma, they should weigh about one-half the above quantities.

Vaginal suppositories should be globular or oviform in shape, and weigh about 10 grammes if made with glycerinated gelatin, and about 4 grammes if made with oil of theobroma.—U. S.

The usual shape of rectal suppositories is that of a cone with a rounded apex (see Figs. 418 and 419), but the difficulty of readily introducing these into the rectum, on account of the resistance offered by contraction of the sphincter muscle, led to the suggestion of a new shape by H. S. Wellcome, of London (1893), as shown in Fig. 420, the great advantages of which become apparent when it is remembered that the bulbous end is inserted into the rectum first, and that as soon as the greatest diameter, which is about ½ inch from the point, has been passed, expulsion of the suppository is

impossible, by reason of the very contractile force of the sphincter, which renders retention of the ordinary conical shape often so difficult.

Fig. 418.



Rectal suppositories (for adults).

Fig. 419.

Rectal suppositories (for children).

Fig. 420.

The Wellcome-shape suppository.

Vaginal suppositories are made either globular or similar to rectal suppositories, as shown in Figs. 421, 422, and 423, while for urethral and nasal bougies the pencil-shape,

Fig. 421.

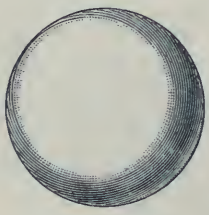


Fig. 422.

Fig. 423.

Vaginal suppositories.

seen in Figs. 424, 425, 426, has been adopted, the last-named being about one-third as long, but twice as thick as the urethral bougies.

Fig. 424.

Urethral bougie.

Suppositories are intended to insure a slow and uniform diffusion of their medicinal constituents to those internal parts to which they may be applied, and the choice of vehicle is made accordingly. The best substance for the preparation of suppositories is undoubtedly cacao butter, or oil of theobroma, first suggested in 1852 by the late A. B.

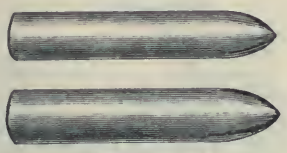
Fig. 425.

The Wellcome-shape urethral bougie.

Taylor, on account of its low fusing-point and bland, non-irritating properties. When medicinal agents, such as volatile oils, and the like, which have a softening effect on the fatty vehicle, are ordered in suppositories, and likewise during the summer season and in warm countries, it will frequently be found impossible to make suppositories with a cacao-butter basis without the addition of spermaceti or wax, which may be used to the extent of 5, 10, or even 20 per cent. of the weight of the fat. At the same time it must be borne in mind that the presence of a considerable quantity of insoluble matter, vegetable or

mineral powders, has the tendency to raise the melting-point of the fat; in some instances the difference has been observed to be as much as 5° or 6° C. (9° or 10.8° F.).

Fig. 426.



Nasal bougies.

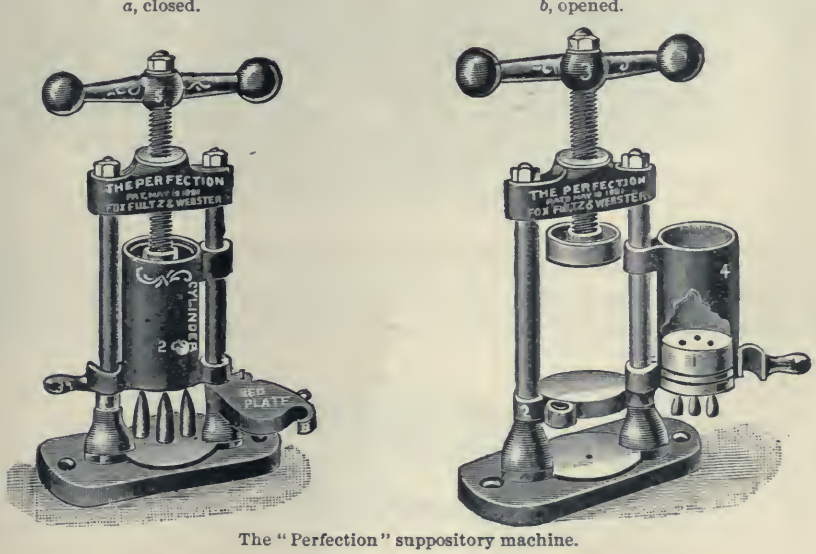
For vaginal suppositories, as well as nasal and urethral bougies, the official glycerinated gelatin, also known as glycerin jelly, is frequently preferred on account of its ready miscibility with water. It is well adapted for the exhibition of solid extracts, as those of belladonna, ergot, and opium, and such substances as boric acid, hydrated chloral, iodine, iodoform, and alkali bromides and iodides, but cannot be used in connection with ichthyol, owing to the fact that ichthyol renders the gelatin insoluble.

Since suppositories are, like ointments, simply mechanical admixtures of the medicinal constituents and a vehicle, the former must always be incorporated in the form of an impalpable powder or in a state of solution, solid extracts being rubbed into a smooth paste with water. On account of the peculiar application of suppositories, it is important that no coarse or gritty particles should ever be contained therein. They are made either entirely by hand, by casting in appropriate molds, or by cold compression in suitable apparatus.

The general official directions given above, if carefully followed, will yield satisfactory results. For hand-made suppositories, which as a rule are not as exact and uniform in shape as those made by fusion, a mixture of oil of theobroma 5 parts, castor oil 1 part, and yellow wax 1 part, melted together and cooled, has been found preferable to oil of theobroma alone, since it is more plastic and yet fuses at about the same temperature; another mixture melting at body-temperature is composed of oil of theobroma 2 parts, lanolin and white wax, of each 1 part. In place of molding suppositories by hand, compression of the finished mass in special molds is largely resorted to, and has proved

Fig. 427.

a, closed. *b*, opened.

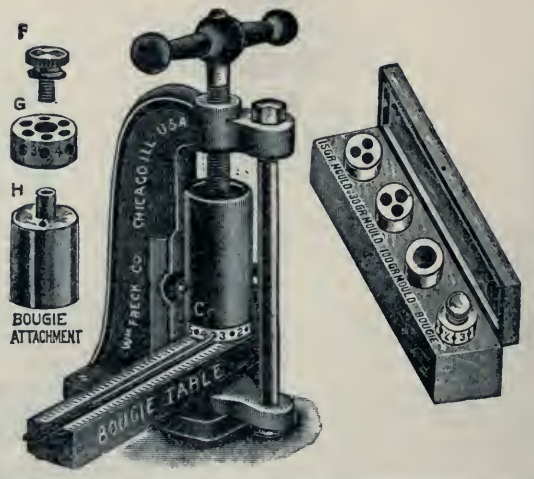


The "Perfection" suppository machine.

very satisfactory. The three molds shown in Figs. 427, 428, and 429 are improvements on the original Archibald compression mold in so far that several rectal suppositories can be compressed at once, while the finished product is easily and quickly removed.

They differ from each other only in the position of the compressor, two being perpendicular and the other horizontal; all, however, require considerable effort to force the

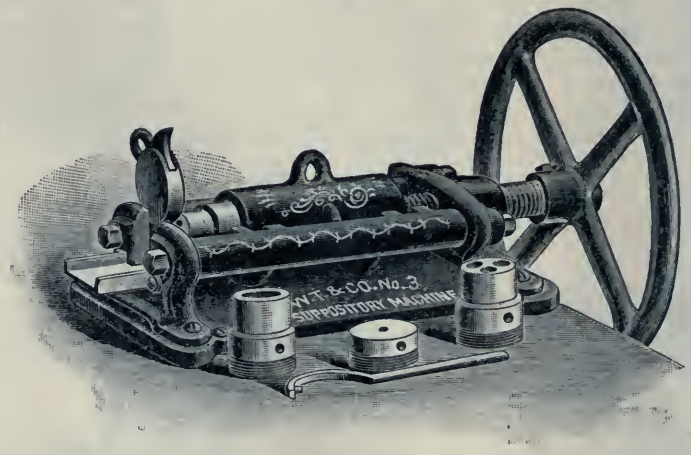
FIG. 428.



Freck's suppository machine with bougie attachment, graduated bougie table, mold-box, and pipe attachment.

mass through the small openings in the top of the molds into the molds proper underneath, which is the only objection that can be urged against them. Bougies, made with

FIG. 429.



Whitall's suppository machine.

glycerin-jelly, are cast in special molds, such as are shown in Figs. 430 and 431; the tubes are usually swabbed with a woolen rag carrying some liquid petrolatum or olive oil, to

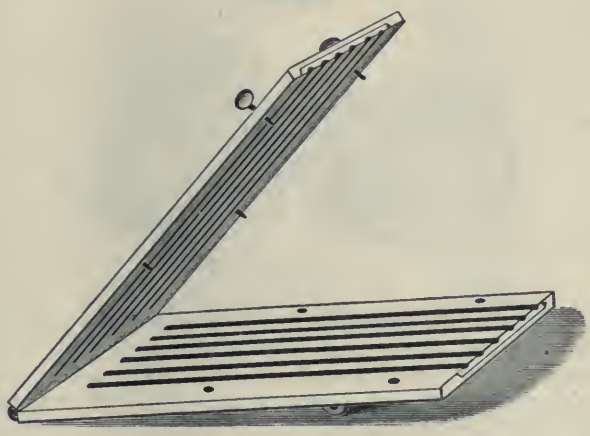
FIG. 430.

Mold for gelatin bougies.

prevent adhesion of the material. When made with cacao-butter or soap and starch they can either be compressed or formed by hand. Nasal bougies should be about 38 millimeters (1½ In.) in length and 6 millimeters (¼ In.) in diameter, while urethral bougies

are usually made 100 millimeters (4 In.) in length and from 3 to 4 millimeters ($\frac{1}{8}$–$\frac{1}{6}$ In.) in diameter. The ends of both are somewhat pointed as shown in Fig. 431.

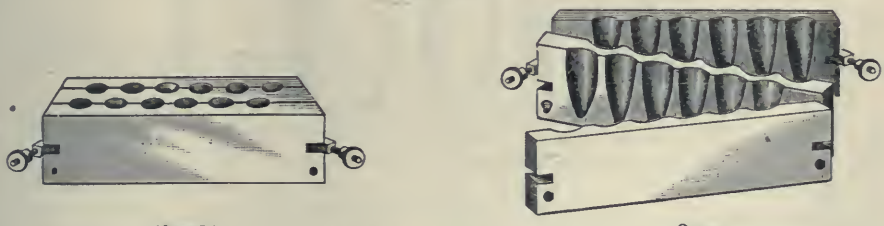
Fig. 431.



Mitchell's urethral bougie mould.

When suppositories are made by fusion, it is important that no heat be applied to the melted vehicle after the addition of the medicinal constituents lest separation occur, particularly in the case of extracts, which cannot afterward be successfully overcome. If perchance the mixture solidifies before it is transferred to the molds, it may again be liquefied by holding the dish or capsule over the steam arising from a hot water-bath and stirring assiduously. The molds must be perfectly clean and dry, having been previously well chilled by placing them on ice; there will then be no occasion whatever for dusting them with lycopodium or other substance. If the fluid mass is of the right con-

Fig. 432.



Closed.' Open

Maris' suppository mold.

sistence and the mold cold, it will immediately congeal and contract on being poured into the molds, but sufficient time should be allowed for the suppository to harden throughout, otherwise trouble may be experienced in removing them; in winter 20 or 30 minutes will suffice, whereas 40 minutes or longer may be necessary in summer, unless the mold,

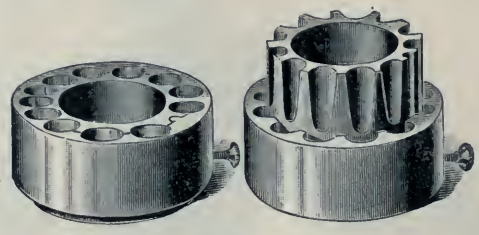
Fig. 433.

Wirz's suppository mold (open).

after having been filled, be placed in an ice-chest. Various styles of molds are in use among pharmacists, those known as divided molds, opening either horizontally or vertically, being preferred on account of the convenience with which they can be taken apart and cleaned. Figs. 432, 433, and 434 represent 3 different styles of molds, from

all of which the suppositories can be quickly removed by bearing slightly with the finger against the conical ends after the molds have been opened.

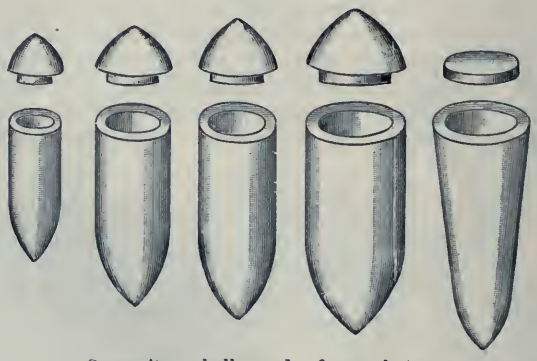
FIG. 434.



See's suppository mold.

Suppository shells made of gelatin or butter of cacao have been introduced for the convenience of the dispenser, but are not used to any extent. The medicinal ingredient is intended to become mixed with the material of the shells as the latter melts, but, as this is uncertain, they should never be used in case of potent remedies or if the direct application of the active agent is likely to cause irritation; for the introduction of boric acid, iodoform, or aristol they are, however, suitable. In the case of butter of cacao shells (see Fig. 435) they are preferably filled with a mixture of the active ingredient

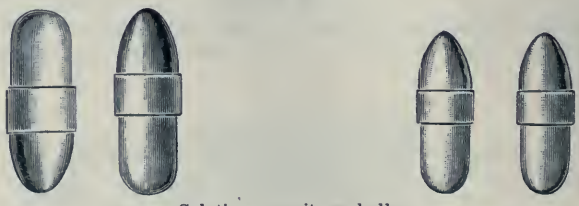
FIG. 435.



Suppository shells, made of cacao-butter.

and grated butter of cacao, and the top sealed either with a warm spatula or a little stiff mucilage of acacia. The gelatin shells (see Fig. 436) may be conveniently sealed

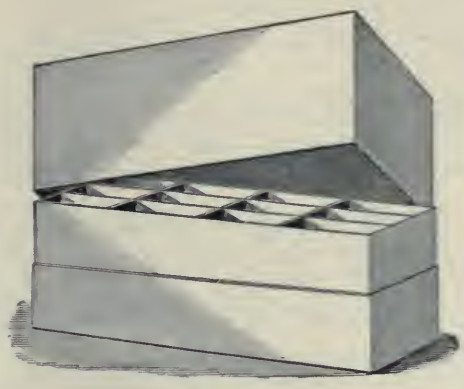
FIG. 436.



Gelatin suppository shells.

by moistening the margin of the lower half with a little water before slipping the upper part over the same. The best method of dispensing suppositories is undoubtedly in partitioned paper boxes (see Fig. 437), the sides and bottom of which should be lined with tinfoil or paraffin paper, the patient always being directed to keep the box in a cool place; in the absence of partitioned boxes, an oblong powder-box may be used, the suppositories being placed between two pieces of sheet-wadding.

FIG. 437.



Suppository box.

SUPPOSITORIA ACIDI CARBOLICI, *Br.*—Phenol Suppositories.

Carbolic acid suppositories, E.; *Suppositoires d'acide phènique*, Fr.; *Phenolsuppositorien*, G.

Preparation.—Take of phenol, 12 grains; white beeswax, 24 grains; oil of theobroma, melted, a sufficient quantity to form, with the phenol and beeswax, a mixture which will fill 12 suitable molds, each capable of holding 15 to 16 grains of oil of theobroma. Dissolve the phenol in the oil of theobroma and beeswax previously melted together at a low temperature, and pour the mixture into the molds; or let the mixture cool, and then divide it into 12 equal parts of a conical or other convenient form for a suppository.—Br.

Uses.—This suppository is disinfectant and locally anæsthetic, and may be used in inflammatory conditions of the rectum attended with purulent and fetid discharge and pain.

SUPPOSITORIA ACIDI TANNICI, *Br.*—Tannic Acid Suppositories.

Suppositoires de tannin, Fr.; *Tanninsuppositorien*, G.

Preparation.—Take of tannic acid, 36 grains; oil of theobroma, a sufficient quantity to form with the tannic acid a mixture which will fill 12 suitable molds, each capable of holding 15 to 16 grains of oil of theobroma. Melt the oil of theobroma; triturate the tannic acid intimately with a little of the oil, and add to the remainder; stir well; as the mixture begins to thicken pour it into the molds; or let the mixture cool and divide it into 12 equal parts of a conical or other convenient form for a suppository.—Br.

Uses.—Tannic acid suppositories are used to diminish local discharges of vagina and rectum, and to constringe the rectal mucous membrane, and thus relieve hemorrhoids and prolapsus.

SUPPOSITORIA BELLADONNÆ, *Br.*—Belladonna Suppositories.

Suppositoires de belladone, Fr.; *Belladonnasuppositorien*, G.

Preparation.—Take of alcoholic extract of belladonna, 18 grains; oil of theobroma, a sufficient quantity for 12 suppositories. Proceed as directed for tannic acid suppositories.—Br.

Each of these suppositories contains 1½ grains of alcoholic extract of belladonna, or approximately $\frac{1}{60}$ grain of the alkaloids of belladonna root.

Uses.—These suppositories are useful to relieve painful conditions of the rectum, bladder, and other pelvic organs. The quantity of extract of belladonna in each is unnecessarily large.

SUPPOSITORIA GLYCERINI, *U. S., Br.*—Glycerin Suppositories.

Suppositoires de glycerin, Fr.; *Glycerinsuppositorien*, G.

Preparation.—Take of glycerin, 30 Gm.; monohydrated sodium carbonate, 0.5 Gm.; stearic acid, 2 Gm.; water, 5 Cc. Dissolve the monohydrated sodium carbonate in the water and add it to the glycerin, contained in a dish, on a water-bath; add the stearic acid, and heat the mixture carefully until the carbon dioxide ceases to be evolved, and the liquid is clear. Then pour the melted mass into suitable molds, remove the suppositories when they are completely cold, and preserve them in tightly stoppered glass vessels.—U. S.

To make a dozen glycerin suppositories use glycerin 556 grains, monohydrated sodium carbonate 10 grains, stearic acid 37 grains, and water 1½ fluidrachms.

Take of gelatin, cut small, ½ ounce, glycerin, by weight, 2½ ounces; distilled water, a sufficiency; place the gelatin in a weighed evaporating dish with sufficient water to cover it; after allowing it to stand for a minute or two, pour away the excess of water; set aside until the gelatin is quite soft, then add the glycerin. Dissolve over a water-bath, and evaporate until the mixture weighs 1563 grains. Pour the product into suppository molds holding 30, 60, or 120 grain-measures, or having other capacities as required. Each suppository contains 70 per cent. by weight of glycerin.—Br.

The two formulas differ somewhat: the mass made by the U. S. P. formula contains about 23 per cent. more of glycerin than that of the Br. P. In the former, sodium stearate is obtained as a result of the reaction between sodium carbonate and stearic acid; thus, $Na_2CO_3.H_2O + 2HC_{18}H_{35}O_2 = 2NaC_{18}H_{35}O_2 + CO_2 + 2H_2O$. Since each molecule of stearic acid is capable of forming one molecule of sodium stearate, 2 Gm. will form 2.155 + Gm. in the U. S. P. process, and if all the water be expelled, the official mass will weigh about 32.155 Gm. and contain about 93 per cent. of glycerin. Each official glycerin suppository will weigh about 50 grains (3.22 Gm.).

Uses.—Glycerin suppositories are extensively employed to relieve constipation. Their action is partly mechanical and in part due to the stimulating action of the glycerin upon the mucous membrane. Their continuous use will result in rectal irritation.

SUPPOSITORIA IODOFORMI, *Br.*—Iodoform Suppositories.

Suppositoires d'iodoforme, Fr.; *Iodoformsuppositorien*, G.

Preparation.—Take of iodoform, 36 grains; oil of theobroma, a sufficient quantity for 12 suppositories. Proceed as directed for tannic acid suppositories.—Br.

Uses.—In addition to the curative influence of iodoform in inflammations of the rectum this suppository is of particular service to allay the pain of hemorrhoids, fissure in ano, ulcerations, etc. It should be inserted a few minutes before defecation when that act is painful.

SUPPOSITORIA MORPHINÆ, *Br.*—Morphine Suppositories.

Suppositoires de morphine, Fr.; *Morphiumsuppositorien*, G.

Preparation.—Take of morphine hydrochloride, 3 grains; oil of theobroma, a sufficient quantity for 12 suppositories. Proceed as directed for tannic acid suppositories.—Br.

Uses.—Besides the employment of this suppository to produce the systemic effect of morphine, it is an useful remedy to relieve the pain, strangury, and tenesmus of inflammations of the rectum and bladder.

SUPPOSITORIA PLUMBI COMPOSITA, *Br.*—Compound Lead Suppositories.

Suppositoires de plomb composès, Fr.; *Zusammengesetzte Bleisuppositorien*, G.

Preparation.—Take of lead acetate, in powder, 36 grains; opium, in powder, 12 grains; oil of theobroma, a sufficient quantity to make 12 suppositories. Proceed as directed for tannic acid suppositories.—Br.

Uses.—The combined astringent and anodyne qualities of this suppository render it appropriate in hemorrhoids, rectal ulceration and hemorrhage, dysentery, diarrhœa, etc.

SYMPHYTUM.—Comfrey Root.

Radix symphyti, R. consolidæ majoris.—Blackwort, Bruisewort, Slippery-root, Gum-plant, Ass-ear, E.; *Schwarzwurz, Beinwurz,* G.; *Grande consoude,* Fr.

The dried root of *Symphytum officinale* L. (Fam. *Boraginaceæ*). The dried leaves are employed almost as extensively as the root.

Origin and Description.—Comfrey is a coarse, bristly-hairy perennial herb, native of Europe, and escaped sparingly in the United States. The leaves are 10 to 25 Cm. (4–10 In.) long, the lowest ovate, the upper successively narrower, acute at the summit, tapering or contracted into a long, broad petiole, pinnately veined, rough, thickish, and mucilaginous. The 5-merous flowers are borne in terminal racemose cymes, the corollas yellowish or purplish white, tubular-campanulate, the throat partly or wholly closed by five linear scales. The root is dug in autumn or early spring and loses about 80 per cent. in drying.

Fig. 438.

Comfrey root (Nat.).

Comfrey-root occurs in pieces from a fraction of an inch to several inches in length, and rarely exceeding 6 Mm. (¼ In.) in thickness, usually much bent, and very deeply, heavily, and roughly wrinkled, and purplish black externally; fracture, when perfectly dry, short, sharp, the fractured surface of a peculiar grayish blue-white color and waxy lustre; bark about one-fourth of the radius, its outer layer blackish; medullary rays broad, wood-wedges narrow; inodorous, very mucilaginous, faintly sweetish, and astringent.

Constituents.—The most important constituent of symphytum is its very large amount of gum. Starch is present in very small amount, giving a brown color with iodine. Graimer reports having isolated the alkaloid *symphyto-cynoglossine* in very small amount, which has a "paralyzing effect on the nerve-centre," and the glucosidal alkaloid *consolidin*, having a similar action to the preceding, and yielding the alkaloid *consolicine*, three times as active as its glucoside. These results would appear to require verifying.

Action and Uses.—Comfrey root is demulcent and mildly astringent. It was used to allay cough and to soothe the irritation of diarrhœa and dysentery, and was given in decoction *ad libitum*.

SYRUPI.—Syrups.

Syrups are concentrated solutions of sugar, the solvent being either water or an aqueous, acetous, or hydroalcoholic solution of some medicinal or aromatic principle. In the United States and British Pharmacopœias the title *Syrupus—Syrup* is used to designate a nearly saturated solution of sugar in water; in practice this solution is usually termed *simple syrup* as a mark of distinction, and this plan is also followed in the French and German pharmacopœias.

Sugar is soluble in half its weight of water at 15° C. (59° F.), and a saturated solution thus prepared has the specific gravity 1.345, or 1.340 if taken at 25° C. (77° F.). Large quantities of sugar dissolved in water very materially increase the bulk of the liquid, a fact which must always be borne in mind in the preparation of syrups; practically, two-thirds of the weight of sugar will equal its bulk in fluid measure, or, in other words, 750 Gm. of sugar, when dissolved in water, will increase the bulk of the liquid by nearly 500 Cc. The proper proportion of sugar to menstruum is of great importance, as upon it depends the stability of the syrup. Should the sugar be deficient in quantity it will not efficiently protect the other organic principles present, and the syrup is liable to ferment. On the other hand, if too much sugar be dissolved by the aid of heat, the excess will crystallize out after cooling and dispose an additional quantity to separate in like manner, thus leaving the syrup weaker in sugar than it should be, and subject to similar alterations as if an insufficient quantity of sugar had been used. As a rule, 65 parts of sugar should require 35 parts of water, but for colder climates a little more water may be used. The British Pharmacopœia directs 50 parts of water for 100 parts of sugar, and the German Pharmacopœia 40 parts of water to 60 parts of sugar, in making simple syrup. If alcohol be present in the menstruum, less sugar will be taken up by the

liquid than in the case of pure water, as shown by the following table, but at the same time less sugar is required to insure stability owing to the preservative properties of the alcohol.

SOLUBILITY OF CANE-SUGAR IN MIXTURES OF ALCOHOL AND WATER. (According to Schufeldt.)

Percentage of Alcohol in the Mixture. By Volume.	By Weight.	Percentage of Sugar in Solution.	Number of Grammes of Sugar soluble in 100 Cc. of the Mixture.
0.	0	66.20	195.8
6.	5	64.25	179.7
12.	10	62.20	164.5

Preparation.—In the preparation of syrups, solution of the sugar may be effected by one of the following methods: Agitation of sugar and solvent without heat, cold percolation of the sugar with the solvent, gentle heating of the sugar and solvent, or heating the mixture of sugar and solvent to the boiling-point. The application of heat in the manufacture of syrups should be avoided as far as possible, especially a boiling temperature, partly to prevent the loss of volatile constituents and partly to guard against any change in the character of the sugar, which, under the influence of heat and particularly with acid liquids, is converted into inverted sugar, resembling glucose, and thereby predisposed to fermentation; moreover, the use of heat in open vessels causes evaporation of a part of the solvent, which, if not restored, produces a supersaturated solution with the attending evil of crystallization referred to above.

The preparation of syrups without heat is a feature of American pharmacy, both the British and German pharmacopœias directing the use of heat in every instance. By some authorities it is claimed that syrups made with heat are more permanent than those made cold; this claim is not supported by experience in this country. For all syrups containing volatile principles or such as may be changed by heat, the cold process is decidedly preferable, and if pure sugar be used, such syrups keep admirably.

The process of cold percolation of sugar with the solvent was first suggested by L. Orinsky in 1871, and is now officially recommended in the preparation of several syrups; the process is of decided advantage whenever the syrup is to be prepared without heat, although it requires a little care in its management so as to insure perfect solution and a clear percolate. A cylindrical, slightly tapering percolator is best adapted for the purpose, and the mode of procedure as given under SYRUPUS has been found satisfactory. If the absorbent cotton has been properly adjusted, the solution will be perfectly clear and transparent, and pass out in drops only, all the sugar being taken up before the end of the process; but if the liquid passes too rapidly, or if it be turbid, it must be poured back into the percolator until the defect is remedied. It will be found advantageous to close the lower orifice of the percolator with a sound cork (or if a rubber tube be used, to tie the same up on the side of the percolator) as soon as the menstruum reaches the cotton, and allow it to remain closed for a short while, possibly an hour or two, so that the menstruum may have an opportunity of becoming saturated, and thus a more gradual and more satisfactory flow of the percolate be established. Some objections have been made to this process, such as the time necessary for perfect solution of the sugar, and the fact that albuminous principles liable to induce fermentation are best removed by heat; but it must be borne in mind that cold percolation requires very little attention after it has once been started, can be allowed to go on during the night, and does away with the necessity of subsequent filtration; the evil tendency of nitrogenized principles in the solvent may be overcome by the use of weak alcohol and glycerin, as is directed in many of the official formulas.

In the case of some syrups, where the viscid character of the solvent precludes rapid solution of the sugar, a moderate heat may be employed to facilitate solution, by putting the sugar and solvent into a strong bottle 1½ times as large as the required volume of syrup, and, after securely corking, keeping it in a water-bath at a temperature of about 50° C. (122° F.), and frequently agitating until perfect solution is effected; all loss of volatile principles is avoided by keeping the bottle well corked. Whenever the solvent contains latent ferments or a large proportion of albuminous matter, heating to the boiling-point is necessary, in order to render such principles harmless, as in the case of syrups prepared from fruit juices; but the heat should not be continued beyond the boiling-point, to avoid a change in the sugar.

When large quantities of syrup are to be made with heat, the mixture of sugar and solvent is placed in a porcelain-lined or well-tinned kettle and heated over a direct fire or on a steam-bath until the sugar is dissolved; it is then strained and water added to make up the desired volume.

Preservation.—Syrups are best preserved in completely filled bottles, in a cool place, and will keep unaltered for a long time if properly prepared; the addition of preservatives, such as salicylic or boric acid, calcium sulphite, ether, etc., is unnecessary, and, in fact, objectionable, and such syrups as cannot be kept with ordinary care should be made in small quantity only. It is well known that syrups containing acids gradually show a change in the sugar from cane-sugar to inverted sugar, and it has been shown by Woltersdorf and Richtmann, 1900, that the inversion is in direct proportion to the temperature to which the syrup is exposed; also that mineral acids cause greater inversion than organic acids, and that the presence of neutral salts in the syrup has the tendency to retard the inverting action of the acid. Air and heat are far more detrimental to the stability of sugar solutions than diffused light; but direct sunlight should always be avoided on account of the heat transmitted by the sun's rays. When syrups have undergone fermentation they are no longer fit for use, and even if the attempt be made to restore them by boiling, they are likely soon to spoil again, owing to the decreased proportion of sugar left in solution; the best and safest plan is to throw them away. Finished syrups should always be put into perfectly *clean and dry* bottles (if made by heat, not until they have become cold), so as to avoid dilution and possible contamination with fermentation germs, which are likely to lurk in imperfectly cleaned bottles. Bottles from which syrups have been dispensed should be thoroughly washed with weak lye and afterward with water, and then dried before they are refilled.

All syrups, whether made by cold or hot process (except cold percolation), require straining through flannel, previously moistened and expressed, to remove particles of dust and dirt; and in the case of colorless or light-colored syrups, their appearance will be greatly improved by filtering them, under cover, through paper or a pledget of cotton.

SYRUPUS, *U. S., Br.*—Syrup.

Sirupus simplex, P. G.; *Sirop de sucre*, Fr. Cod.; *Syrupus sacchari, Syrupus albus.*—*Simple syrup*, E.; *Sirop de sucre, Sirop simple*, Fr.; *Weisser Sirup*, G.

Preparation.—Sugar, in dry crystalline granules, 850 Gm.; distilled water, a sufficient quantity to make 1000 Cc. Dissolve the sugar, with the aid of heat, in 450 Cc. of distilled water, raise the temperature to the boiling-point, strain the liquid, and pass enough distilled water through the strainer to make the product, when cold, measure 1000 Cc. Mix thoroughly.—U. S.

Syrup may also be prepared in the following manner: Press down into the neck of a percolator of suitable size a pledget of purified cotton, not too tightly, and in such a manner that the cotton shall nearly fill the neck of the percolator, and moisten it with a few drops of distilled water. Place the sugar in the apparatus, make its surface level without shaking or jarring, then carefully pour on 450 Cc. of distilled water, and regulate the flow of the liquid, if necessary, so that it will pass out in rapid drops. Return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by distilled water, added in portions, so that all the sugar may be dissolved, and the product measure 1000 Cc. Mix thoroughly.—U. S.

To make 1 gallon of simple syrup dissolve 7 pounds 1½ avoirdupois ounces of sugar in 61 fluidounces of distilled water, and when cold add sufficient distilled water to bring the volume to 1 gallon.

The official syrup thus prepared has the specific gravity 1.313 at 25° C. (77° F.), and contains 64.54 per cent. of sugar. The British Pharmacopœia orders 5 pounds of sugar and sufficient distilled water to make 7½ pounds of syrup, which contains 66.667 per cent. of sugar, and is stated to have the density of 1.330 at 15.6° C. (60° F.). The French Codex orders 64.286 per cent. of sugar, and gives the density 1.32. The German Pharmacopœia orders 60 per cent. of sugar.

Pharmaceutical Uses.—Simple syrup is used in the preparation of certain confections, mixtures, and syrups, and as an excipient in several pill masses.

Uses.—Syrup is used to preserve medicines added to it, and to render them more palatable.

SYRUPUS ACACIÆ, *U. S.*—Syrup of Gum-Arabic.

Syrupus gummosus.—Sirop de gomme. Fr.; *Gummisirup,* G.

Preparation.—Acacia, in selected pieces, 100 Gm.; sugar, 800 Gm.; distilled water, 430 Cc. Introduce the acacia into an enamelled or porcelain dish, add the distilled water, and stir occasionally until the acacia is dissolved; then, having added the sugar, place the dish on a water-bath and apply heat, gradually increasing the temperature, and stirring from time to time until the sugar is dissolved. Strain the syrup, if necessary, and add sufficient distilled water to make the product measure 1000 Cc.—U. S.

To make a pint of syrup of acacia, dissolve 800 grains of acacia in 6¾ fluidounces of distilled water, add 14¾ avoirdupois ounces of sugar, dissolve by aid of gentle heat, strain and add sufficient distilled water to make 16 fluidounces. When small quantities of the syrup are wanted extemporaneously, 50 grains of granulated acacia may be dissolved in sufficient simple syrup to make 1 fluidounce.

Syrup of acacia should be preserved in small well-filled bottles in a cool place. In summer time it sours readily.

Uses.—Syrup of acacia is useful as a demulcent in mild inflammations of the larnyx and throat, but is chiefly employed as an agent to suspend active substances in mixtures from which they would otherwise be precipitated.

SYRUPUS ACIDI CITRICI, *U. S.*—Syrup of Citric Acid.

Sirup d'acide citrique, Sirop de limon, Fr.; *Citronsäuresirup,* G.

Preparation.—Citric acid, 10 Gm.; distilled water, 10 Cc.; tincture of fresh lemon peel, 10 Cc.; syrup, a sufficient quantity to make 1000 Cc. Dissolve the citric acid in the distilled water, and mix the solution with 500 Cc. of syrup. Then add the tincture of fresh lemon peel, and lastly enough syrup to make the product measure 1000 Cc. Mix thoroughly.—U. S.

To make a pint of syrup of citric acid will require 72 grains of citric acid, 80 minims each of water and tincture of fresh lemon peel, and sufficient syrup to bring the volume of the finished product up to 16 fluidounces.

Uses.—This syrup is used as a flavoring agent as a substitute for syrup of lemon.

SYRUPUS ACIDI HYDRIODICI, *U. S.*—Syrup of Hydriodic Acid.

Sirop d'acide iodhydrique, Fr.; *Jodwasserstoffsirup,* G.

A syrupy liquid, containing about 1 per cent., by weight, of absolute hydriodic acid, or about 1.19 Gm. in 100 Cc.—U. S.

Preparation.—Diluted hydriodic acid, 100 Gm.; water, 300 Gm.; syrup, 600 Gm. Mix them.—U. S.

To make a pint of syrup of hydriodic acid, mix 868 grains of diluted hydriodic acid with 5½ fluidounces of water and add sufficient syrup to make the product measure 16 fluidounces.

This formula differs materially from that of the last two editions of the Pharmacopœia, and is intended to eliminate the annoying feature of caramelization caused by the prolonged action of the acid liquid on the sugar. It should only be made in small quantities to suit the demand, or prepared extemporaneously as called for.

Properties and Tests.—Syrup of hydriodic acid is a transparent, colorless, or not more than pale straw-colored liquid, odorless, and having a sweet and acidulous taste. Its specific gravity is about 1.190 at 25° C. (77° F.). If a small portion of the syrup be mixed with a little starch test-solution, and a few drops of chlorine-water then added

the liquid will acquire a deep-blue color. Not more than a faint bluish tint should be produced in the syrup by starch test-solution alone (limit of free iodine). The addition of silver nitrate test-solution to a small portion of the syrup diluted with 4 volumes of water produces a pale-yellow precipitate, nearly insoluble in ammonia-water. If 31.73 (31.725) Gm. of syrup of hydriodic acid be diluted with distilled water to measure 50 Cc., and if to 10 Cc. of this solution about an equal volume of distilled water, 8 Cc. of tenth-normal silver nitrate solution, and 5 Cc. of diluted nitric acid be added, followed by 3 Cc. of ferric ammonium sulphate test-solution, then, after thoroughly shaking the mixture, not more than 3 Cc. of tenth-normal potassium sulphocyanate solution should be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate solution consumed corresponding to 0.2 per cent. of absolute hydriodic acid).—U. S. When freshly made, syrup of hydriodic acid is colorless, but slowly assumes a yellowish tint, which is not due to the liberation of iodine, but is caused by the gradual action of the acid on the sugar.

Uses.—Syrup of hydriodic acid is given for its iodine influence. It is preferred by some practitioners to the alkaline iodides in the treatment of scrofulosis in children, and in chronic interstitial nephritis. It is a rather weak preparation, given in the dose of from ½ to 2 drachms (2–8 Cc.).

SYRUPUS ALTHÆÆ.—Syrup of Althæa.

Sirupus althææ, P. G.—*Syrup of marshmallow*, E.; *Sirop de guimauve*, Fr.; *Eibisch-sirup*, G.

Preparation.—Althæa, cut in small pieces, 2 parts; alcohol, 1 part; water, 50 parts; sugar, 63 parts. Wash the althæa with cold water, then add it to the alcohol and water previously mixed, and allow the mixture to stand for 3 hours at a temperature of 15° to 20° C. (59°–68° F.) without stirring. Strain without expression, and to 37 parts of the strained liquid add the sugar, and dissolve by aid of a gentle heat. When cool, add enough water to make the product equal 100 parts.—P. G.

Syrup of althæa has a yellowish color and a slight rather agreeable odor. It spoils quite readily, especially in warm weather, and should always be kept in small well-filled bottles in a cool place. The presence of 10 per cent. by volume of glycerin, as recommended in the 1890 U. S. Pharmacopœia, has been found to aid materially in preserving the syrup.

Uses.—This syrup has demulcent properties which render it of some value in sore throat. Its dose is from 1 to 4 drachms (4–16 Cc.).

SYRUPUS AMYGDALÆ, *U. S.*—Syrup of Almond.

Sirupus amygdalarum, P. G.; *Sirupus emulsivus.—Sirop d'amande, Sirop d'orgeat*, Fr.; *Mandelsirup*, G.

Preparation.—Spirit of bitter almond, 10 Cc.; orange flower water, 100 Cc.; syrup, a sufficient quantity to make 1000 Cc. Mix them.—U. S.

Take of sweet almonds, 15 parts; bitter almonds, 3 parts; water, 40 parts; sugar, 60 parts. Having blanched the almonds, prepare an emulsion with the aid of the water, and dissolve the sugar in 40 parts of the strained liquid with the aid of a gentle heat.—P. G.

The present official syrup of almond is an entirely different preparation from that of the 1890 Pharmacopœia, which closely resembled the syrup of German pharmacy. The syrup is rarely used in this country, and when ordered by French or German physicians, the preparation made by the second formula given above should be dispensed. The official syrup of almond has only a very faint color and the characteristic odor of bitter almond and orange flowers, whereas the German syrup is whitish and yields a milk-like liquid when diluted with water. Although the syrup of the U. S. P., 1890, did not keep well in warm weather, we think it would have been better to drop it entirely than to introduce the present syrup, so entirely different from the former, and hardly acceptable to the few physicians who use syrup of almond and are familiar with its appearance and taste.

Uses.—Syrup of almond is demulcent and slightly sedative. It is an agreeable addition to expectorant and diuretic mixtures. It is given in the dose of 1 to 2 drachms (4–8 Cc.).

SYRUPUS AROMATICUS, *Br.*—Aromatic Syrup.

Sirop aromatique, Fr.; *Aromatischer Sirup*, G.

Preparation.—Take of tincture of orange, 5 fluidounces; cinnamon water, 5 fluidounces; syrup, 10 fluidounces. Mix the tincture of orange and cinnamon water; shake the mixture with a little powdered talc; filter and add the syrup.—Br.

When tincture of orange and cinnamon water are mixed, turbidity results on account of the oil present in the tincture, and hence filtration through talc becomes necessary.

Uses.—The syrup is used solely as a flavoring agent, and somewhat resembles the aromatic elixir of the U. S. Pharmacopœia.

SYRUPUS AURANTII, *U. S., Br.*—Syrup of Orange.

Sirupus aurantii corticis, P. G.—*Syrup of orange peel*, E.; *Sirop d'écorce d'orange amère*, Fr.; *Pomeranzenschalensirup*, G.

Preparation.—Tincture of sweet orange peel, 50 Cc.; citric acid, 5 Gm.; magnesium carbonate, 10 Gm.; sugar, 820 Gm.; water, a sufficient quantity to make 1000 Cc. Triturate the magnesium carbonate in a mortar with the tincture, add gradually 400 Cc. of water, filter, and add sufficient water through the filter to obtain 450 Cc. of filtrate; in this dissolve the citric acid and sugar by agitation without heat, and add sufficient water to make the product measure 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of orange triturate 7 fluidrachms of tincture of sweet orange peel with 75 grains of magnesium carbonate, add 6¾ fluidounces of water, mix well, filter, and pass sufficient water through the filter to obtain 7½ fluidounces of filtrate; in this dissolve 40 grains of citric acid and 14 avoirdupois ounces of sugar, finally adding sufficient water to bring the volume up to 16 fluidounces.

Tincture of orange, 1 fluidounce: syrup, 7 fluidounces. Mix.—Br.

The corresponding syrups of the French and German Pharmacopœias are made with bitter orange peel, which, according to the former authority, is exhausted with alcohol of 6 per cent., and, according to the latter, with white wine; in the tincture thus obtained the sugar is dissolved.

The present official syrup of orange differs but slightly from that of 1890, except that it represents only about ½ as much fresh sweet orange peel and contains a slight proportion of citric acid, about 0.005 Gm. per Cc. or 2½ grains per fluidounce. It has a yellowish color and a pleasant acidulous taste.

The syrup of the British Pharmacopœia is made with tincture of orange prepared from fresh bitter orange peel. It is a slightly opalescent preparation, owing to partial precipitation of the oil held in solution in the tincture. If the syrup be mixed with water, the turbidity becomes more marked.

A fluidextract of sweet orange peel is sometimes offered for the preparation of syrup of orange, but should never be used, as it is made from dried peel with a hydro-alcoholic menstruum and forms dark-colored mixtures when added to solutions containing tincture of iron.

Uses.—This syrup is merely a pleasant flavoring agent.

SYRUPUS AURANTII FLORUM, *U. S.*—Syrup of Orange Flowers.

Syrupus aurantii floris, Br.—*Sirop de fleur d'oranger*, Fr.; *Pomeranzenblüthensirup*, G.

Preparation.—Sugar, 850 Gm.; orange flower water, a sufficient quantity to make 1000 Cc. Dissolve the sugar in 450 Cc. of orange flower water by agitation, without heat, add enough orange flower water to make the product measure 1000 Cc., and mix thoroughly.—U. S.

Syrup of orange flowers may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under SYRUP. Pour 450 Cc. of orange flower water upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by orange flower water until the product measures 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of orange flowers dissolve 14 avoirdupois ounces of sugar in 7¼ fluidounces of orange flower water, and add sufficient of the latter to bring the volume of the solution up to 16 fluidounces.

Dissolve 3 pounds of refined sugar in 16 fluidounces of boiling distilled water; strain, and when nearly cold add 8 fluidounces of undiluted orange-flower water of commerce, and sufficient recently boiled distilled water to make the product weigh 4½ pounds.—Br.

Uses.—This syrup is used for its agreeable taste. Its dose is ½ to 2 drachms (2–8 Cc.).

SYRUPUS CALCII LACTOPHOSPHATIS, *U. S., Br.*—Syrup of Calcium Lactophosphate.

Sirop de lactophosphate (phospholactate) de chaux, Fr.; *Calciumphospholactatsirup*, G.

Preparation.—Precipitated calcium carbonate, 25 Gm.; lactic acid, 60 Cc.; phosphoric acid, 36 Cc.; orange flower water, 50 Cc.; sugar, 725 Gm.; water, a sufficient quantity to make 1000 Cc. To the lactic acid, mixed with 100 Cc. of water and contained in a capacious mortar, gradually add the calcium carbonate, in portions, until it is dissolved. Then add the phosphoric acid, diluted with 50 Cc. of water, and triturate until the precipitate at first formed has disappeared. Add 100 Cc. of water, and filter, rinsing the mortar with 50 Cc. of water, and passing the rinsings through the filter. To the mixed filtrates add the orange flower water, and, having added the sugar, dissolve it by agitation without heat, and strain. Lastly, pass enough water through the strainer to make the product measure 1000 Cc., and mix thoroughly.—U. S.

To make 1 pint of syrup of calcium lactophosphate dissolve 183 grains of precipitated calcium carbonate in 7¾ fluidrachms of lactic acid diluted with 13 fluidrachms of water; add 276 minims of phosphoric acid, diluted with 1 fluidounce of distilled water, and triturate until perfect solution is effected. Now add 7 fluidrachms of water, filter, and wash filter with 6 fluidrachms of water; to the filtrate add 6 fluidrachms of orange flower water and 12½ avoirdupois ounces of sugar. Shake until dissolved, strain, and add sufficient water through the strainer to bring the volume up to 16 fluidounces.

The syrup of the British Pharmacopœia is identical with the above, except that it contains less orange flower water.

Calcium carbonate is readily dissolved by the diluted lactic acid, and upon the addition of phosphoric acid calcium phosphate is formed, which is held in solution by the lactic acid and excess of phosphoric acid present. Each Cc. of the finished syrup contains the equivalent of 0.02584 Gm., or each fluidrachm the equivalent of 1.48 grains of tricalcium phosphate ($Ca_3(PO_4)_2$).

The formula of the French Codex is as follows: Dissolve 12.5 Gm. of calcium phosphate in sufficient (14 Gm.) concentrated lactic acid and 340 Gm. of water; 630 Gm. of sugar are dissolved in the liquid, and 10 Gm. of essence of lemon added. Replacing the lactic acid by a sufficient quantity of hydrochloric acid, *sirop de chlorhydrophosphate de chaux* is obtained. *Sirop de phosphate acide de chaux* is made in the same manner, using sufficient phosphoric acid for dissolving the calcium salt.

Uses.—In scrofulosis and strumous states and allied conditions, as rickets, when it is desired to obtain the effect of phosphates upon the system, this preparation may be given with benefit in the dose of 1 to 4 drachms (4–16 Cc.).

SYRUPUS CALCIS, *U. S.*—Syrup of Lime.

Syrupus calcariæ.—Syrup of calcium hydroxide, E.; *Sirop de chaux*, Fr.; *Kalksirup*, G.

Preparation.—Lime, 65 Gm.; sugar, 350 Gm.; water, a sufficient quantity to make 1000 Cc. Slake the lime by the addition of 35 Cc. of water with the aid of heat, then mix it and the sugar thoroughly in a mortar, so as to form a homogeneous powder; add the mixture to 500 Cc. of boiling water, contained in a bright copper or tinned iron vessel, and boil for 5 minutes, constantly stirring. Dilute the liquid with sufficient water to make it measure 950 Cc., and filter through white paper, closely covering the funnel during filtration. Then add through the filter enough water to make the product measure 1000 Cc., and mix thoroughly. Keep the syrup in well-stoppered bottles.—U. S.

To make 1 pint of syrup of lime slake 1 avoirdupois ounce of lime with ½ ounce of

water, mix thoroughly with 7 avoirdupois ounces of sugar and add to 9 fluidounces of boiling water, and boil for 5 minutes. Dilute the mixture to 15½ fluidounces, filter, and add sufficient water to bring the volume up to 16 fluidounces. Distilled water is to be preferred in making this syrup.

Advantage is taken, in the preparation of syrup of lime, of the well-known fact that sugar largely increases the solubility of lime in water, and this solubility varies with the proportion of sugar to the water used; according to Peligot, 100 parts of sugar contained in 250 parts of aqueous solution will take up 26.5 parts of lime, while the same quantity of sugar in 2000 parts of solution takes up only 18 parts of lime. Choice lime should be used—as free from carbonate and other impurities as possible. The official syrup of lime is of uncertain strength, the Pharmacopœia not having fixed a definite proportion, but when freshly made it contains probably 0.032 Gm. of calcium oxide in every Cc. The direction to boil the lime, sugar, and water together for 5 minutes is not essential, except to gain time, for cold maceration with frequent agitation will cause an equally large amount of lime to be dissolved; but longer time is necessary —possibly 2 or 3 days.

Properties.—Syrup of lime is a transparent, pale-yellow liquid, of alkaline taste and reaction. Its specific gravity is about 1.145 at 25° C. (77° F.). The addition of a solution of an alkali carbonate produces a white precipitate, soluble in acids with effervescence. The addition of ammonium oxalate test-solution produces a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid.—U. S. On exposure to air syrup of lime absorbs carbon dioxide rapidly, and it must therefore be kept in well-stoppered vials. The official syrup contains very much more lime in solution than the saccharated solution of lime of the British Pharmacopœia (see LIQUOR CALCIS SACCHARATUS, which latter represents about 7½ grains in 1 fluidounce).

Uses.—This preparation presents no advantages over lime-water; in fact, because of the sugar present it is less desirable for many conditions, as gastric acidity and acid diarrhœa, in which lime is beneficial. It contains a much larger percentage of lime than does the official liquor, and its dose is from 20 to 60 minims (1.30–4 Cc.).

SYRUPUS CASCARÆ AROMATICUS, *Br.*—Aromatic Syrup of Cascara.

Sirop aromatique de cascara sagrada, Fr.; *Aromatischer Amerikanisch-Faulbaumrindensirup*, G.

Preparation.—Take of liquid extract of cascara sagrada 8 fluidounces; tincture of orange, 2 fluidounces; alcohol (90 per cent.), 1 fluidounce; cinnamon water, 3 fluidounces; syrup, 6 fluidounces. Mix.—Br.

This syrup is intended to present cascara in a more pleasant form, and contains in each teaspoonful the active virtues of 24 grains of cascara sagrada bark. It somewhat resembles the aromatic fluidextract of rhamnus purshiana of the U. S. Pharmacopœia, but contains less than ½ as much cascara sagrada, and is less palatable.

Uses.—Aromatic syrup of cascara may be given whenever the effect of the drug is desired. The dose is from ½ to 2 drachms (2–8 Cc.).

SYRUPUS CERASORUM.—Syrup of Cherries.

Sirupus cerasorum, P. G.—*Sirop des cerises*, Fr.; *Kirschensirup*, G.

Preparation.—Syrup of cherries is directed to be made as follows: Sour black cherries, including the seeds, are crushed, and set aside in a covered vessel at a temperature of about 20° C. (68° F.), with occasional stirring, until a small portion of the liquid after filtration forms a clear mixture with ½ its volume of alcohol. The mixture is then expressed and filtered, and 13 parts of sugar dissolved in every 7 parts of the filtrate, with the aid of heat.—P. G.

Syrup of cherries may be considered as a type of the class of fruit syrups, the above process of manufacture being equally applicable to strawberries, raspberries, currants, blackberries, etc. The object of setting the crushed fruit aside at a moderate temperature, for several days, is to insure the destruction of certain undesirable constituents, known as pectin, which, if allowed to remain in the fruit juice, would cause the syrup to gelatinize. The complete removal of pectin is shown by the test with alcohol, as the filtered juice will not mix clear with ½ its volume of alcohol as long as any pectin is

present; a concentrated solution of magnesium sulphate should also leave the filtered juice unaffected.

After removal of the pectin, the filtered juice should be allowed to subside in well-closed vessels, in a cool place, for 2 or 3 days until clear; the supernatant liquid must be carefully decanted or withdrawn and passed through a previously wetted paper filter. The sugar should be added to the filtrate without delay and dissolved by stirring before the mixture is heated to boiling; any albuminous matter remaining in the juice is coagulated by heating and removed by subsequent straining. The mixture of filtered juice and sugar must not be boiled for any length of time, but the heat should be withdrawn when the syrup begins to boil quietly after the first frothing and rising of the liquid.

Uses.—This syrup is used merely as an agreeable vehicle.

SYRUPUS CHLORAL, *Br.*—Syrup of Chloral.

Sirop de chloral, Fr.; *Chloralhydratsirup*, G.

Preparation.—Take of chloral hydrate 1600 grains; distilled water, 30 fluidrachms; syrup, a sufficient quantity. Dissolve the chloral hydrate in the water, and add the syrup until the mixed product measures 1 imperial pint.—Br.

The syrup of the F. Cod. contains only 5 per cent. of chloral hydrate, and is flavored with spirit of peppermint.

Uses.—This is a superfluous preparation. Each drachm contains 10 grains (0.60 Gm.) of chloral. The usual dose is from 1 to 2 drachms (4–8 Cc.).

SYRUPUS CINNAMOMI.—Syrup of Cinnamon.

Sirupus cinnamomi, P. G.—*Sirop de canelle*, Fr.; *Zimmtsirup*, G.

Preparation.—Take of cassia bark, in coarse powder, 1 part; cinnamon water, 5 parts; sugar, 6 parts. Macerate the cassia bark for 2 days with the cinnamon water warmed to 15° or 20° C. (59° or 68° F.), with frequent agitation. The mixture is then filtered, and in 4 parts of the filtrate the sugar is dissolved with the aid of moderate heat.—P. G.

Syrup of cinnamon has a reddish-brown color and a pleasant characteristic odor and taste.

Uses.—Syrup of cinnamon is merely a pleasant flavoring ingredient for medicinal mixtures.

SYRUPUS CODEINÆ, *Br.*—Syrup of Codeine.

Sirop de codéine, Fr.; *Kodeinsirup*, G.

Preparation.—Take of codeine phosphate 40 grains; distilled water, $\frac{1}{4}$ fluidounce; syrup, $19\frac{3}{4}$ fluidounces. Dissolve the codeine phosphate in the distilled water; add the syrup. Mix.—Br.

Each teaspoonful of the syrup contains $\frac{1}{4}$ grain of codeine phosphate.

Syrup of codeine of the French Codex contains $\frac{1}{5}$ per cent. of the pure alkaloid, and is made by dissolving 0.20 Gm. of codeine in 5 Gm. of alcohol (60 per cent.) and adding the solution to 95 Gm. of syrup.

Uses.—This syrup may be taken for coughs and other conditions in which codeine is indicated. The dose is from 1 to 4 drachms (4–16 Cc.).

SYRUPUS FERRI IODIDI, *U. S.*, *Br.*—Syrup of Ferrous Iodide.

Sirop d'iodure de fer, Fr. Cod.; *Sirupus ferri jodati*, P. G.—*Syrup of iodide of iron*, E.; *Eisenjodürsirup*, G.

A syrupy liquid containing about 5 per cent. by weight of ferrous iodide (FeI = 307.30) or about 6.74 Gm. in 100 Cc.—U. S.

Preparation.—Iron, in the form of fine bright wire, and cut into small pieces, 12.5 Gm.; iodide, 41.5 Gm.; diluted hypophosphorous acid, 20 Cc.; sugar, 600 Gm.; distilled water, a sufficient quantity to make 1000 Gm. Introduce the iron into a flask of thin glass having a capacity of about 500 Cc.; add to it 150 Cc. of distilled water,

and afterward the iodine. Shake the mixture occasionally, checking the reaction, if necessary, by the affusion of cold water, and, when the solution has acquired a greenish color and has lost the odor of iodine, heat it to boiling, and add at once 50 Gm. of the sugar; when this has dissolved, filter the solution into the remainder of the sugar contained in a porcelain dish. Rinse the flask and iron wire with 125 Cc. of distilled water and pass the washings through the filter into the sugar. Stir the mixture with a porcelain or wooden spatula, heating the liquid on a water-bath until complete solution is effected, and, having passed the syrup through a clean muslin strainer into a tared bottle, add the diluted hypophosphorous acid, and sufficient distilled water to make the product weigh 1000 Gm.—U. S.

To make 1 pint of syrup of ferrous iodide, add 125 grains of iron wire to 3 ounces of distilled water contained in a flask, and afterwards 410 grains of iodine. When a pale-green solution has been obtained, free from the odor of iodine, heat it to boiling and add 1 avoirdupois ounce of sugar; shake until dissolved, filter the solution into 12½ avoirdupois ounces of sugar, rinse the flask and wire with 2½ fluidounces of distilled water, and add to the filtrate. Dissolve the sugar with the aid of heat on a water-bath, strain the solution, add 208 minims of diluted hypophosphorous acid and sufficient distilled water to bring the volume up to 16 fluidounces.

The details of the process given above are very similar to those of the British and German Pharmacopœias, except that the latter authority directs the solution of ferrous iodide to be filtered into a prescribed quantity of syrup. The strength of this syrup varies in the different pharmacopœias, thus: While the U. S. P. and German syrups both contain 5 per cent. of ferrous iodide, the British syrup contains 10 per cent., and the French only ½ per cent. The present U. S. P. syrup is of exactly ½ strength of that of 1890. As a preservative of syrup of ferrous iodide, hypophosphorous acid has been found superior to all other substances; it was first suggested by Judge about 1855. Being a strong reducing agent, hypophosphorous acid prevents the oxidation of the ferrous into ferric salt, which would carry with it the liberation of iodine. The decoloration by glucose of syrup of ferrous iodide containing free iodine has been found to be due wholly to the sulphites present in commercial glucose, since pure glucose has no decolorizing effect on solution of iodine.

Properties and Tests.—Syrup of ferrous iodide is a transparent, pale-green liquid, having a sweet, strongly ferruginous taste and a neutral reaction. Its specific gravity is about 1.349 at 25° C. (77° F.) (1.380 to 1.387 Br. at 15.5° C.). On adding a few drops of potassium ferricyanide test-solution to a small portion of the diluted syrup a blue precipitate will be produced. If mixed with a little starch test-solution, and afterwards with a few drops of chlorine water, the syrup will acquire a deep-blue color. This color should not be produced in the syrup by starch test-solution alone (absence of free iodine). If 10 Gm. of syrup of ferrous iodide be diluted with distilled water to measure 100 Cc., and 15.4 (15.36) Cc. of the solution be mixed with 15 Cc. of water, 6 Cc. of tenth-normal silver nitrate solution, and 2 Cc. each of diluted nitric acid and ferric ammonium sulphate test-solution, then, after thoroughly shaking the mixture, not more than 1 Cc. of tenth-normal potassium sulphocyanate solution should be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate solution consumed corresponding to 1 per cent. of ferrous iodide).—U. S. In the foregoing test, after all iodine present as ferrous iodide has been precipitated as silver iodide, the excess of silver added is precipitated as white silver sulphocyanate by the potassium sulphocyanate solution, and then the reddish-brown color due to formation of ferric sulphocyanate becomes permanent. From the equation $FeI_2 + 2AgNO_3 = 2AgI + Fe(NO_3)_2$ it may be seen that 1 Cc. of tenth-normal silver nitrate solution is capable of precipitating 0.015365 Gm. of ferrous iodide.

Uses.—While syrup of ferrous iodide may be employed in anæmia from any cause, it is particularly applicable to those cases of impoverished blood due to scrofulosis and struma, and accompanied by glandular enlargement. It is useful in chronic skin diseases, especially eczema of young children whose vitality is greatly impaired. By some it is considered useful in gonorrhœal rheumatism. Since the present official syrup is only ½ the strength of that of the Pharmacopœia of 1890, its dose is twice as large, from 20 minims to 2 drachms (1.30–8 Cc.). It should be well diluted and taken through a glass tube to prevent its discoloring the teeth.

SYRUPUS FERRI PHOSPHATIS, *Br.*—Syrup of Ferrous Phosphate.

Sirop de phosphate de fer, Fr.; *Eisenphosphatsirup*, G.

Preparation.—Take of iron, in wire, 75 grains; concentrated phosphoric acid (66.3 per cent.), 1¼ fluidounces; syrup, 14 fluidounces; distilled water, a sufficient quantity. Place the iron wire and the concentrated phosphoric acid, previously diluted with an equal volume of distilled water, in a small flask; plug the neck with cotton wool, and heat gently until the iron is dissolved. When cool, filter into the syrup, and pass sufficient distilled water through the filter to make the product measure 1 imperial pint.—Br.

Syrup of ferrous phosphate, which contains an excess of phosphoric acid, represents 1 grain of anhydrous ferrous phosphate in each fluidrachm.

Uses.—This syrup affords a palatable means for administering ferrous phosphate. Its dose is from ½ to 2 drachms (2–8 Cc.).

SYRUPUS FERRI, QUININÆ, ET STRYCHNINÆ PHOSPHATUM, *U. S.*—Syrup of the Phosphates of Iron, Quinine, and Strychnine.

Syrupus ferri phosphatis cum quinina et strychnina, Br.—*Syrup of phosphate of iron with quinine and strychnine, Easton's syrup*, E.; *Sirop tonique d'Easton*, Fr.; *Eisenphosphatsirup mit Chinin und Strychnin. Eastonscher Sirup*, G.

Preparation.—Glycerite of the phosphates of iron, quinine and strychnine, 250 Cc.; syrup, a sufficient quantity to make 1000 Cc.—U. S.

The formula is intended for the extemporaneous preparation of the syrup, by mixing 1 volume of the glycerite of the phosphates of iron, quinine, and strychnine with 3 volumes of syrup.

Take of iron, in wire, 75 grains; concentrated phosphoric acid (66.3 per cent.), 1¼ fluidounces; strychnine, 5 grains; quinine sulphate, 130 grains; syrup, 14 fluidounces; distilled water, a sufficient quantity. Place the iron wire and the concentrated phosphoric acid, previously diluted with an equal volume of distilled water, in a small flask; plug the neck with cotton wool, and heat gently until the iron is dissolved; in the resulting solution dissolve the strychnine and quinine sulphate; filter into the syrup; pass sufficient distilled water through the filter to make the product measure 1 imperial pint.—Br.

The two preparations differ somewhat in composition and strength. The U. S. P. syrup contains the iron in ferric condition, and represents in each fluidrachm about 1¼ grains of soluble ferric phosphate, 1½ grains of quinine, and $\frac{1}{87}$ grain of strychnine, whereas the British syrup contains ferrous salt, and in each fluidrachm represents 1 grain of ferrous phosphate, ⅘ grain of quinine, and $\frac{1}{32}$ grain of strychnine. If the syrup be kept on hand for some time, it will slowly darken, owing to the caramelizing effect of the acid on the sugar.

Uses.—While this is a convenient and elegant preparation, the combination of the ingredients in fixed quantity is not desirable. The average dose is 1 drachm (4 Cc.).

SYRUPUS GLYCYRRHIZÆ.—Syrup of Licorice.

Sirupus liquiritiæ, P. G.; *Sirop de réglisse*, Fr.; *Süszholzsirup*, G.

Preparation.—Licorice root, in very coarse powder, 4 parts; ammonia-water, 1 part; water, 20 parts; alcohol, 2 parts; simple syrup, a sufficient quantity. Macerate the licorice root in the water to which the ammonia-water has been added, for 12 hours, at a temperature of 15° to 20° C. (59°–68° F.), frequently stirring the mixture. Express, heat the liquid to the boiling-point, and evaporate on a water-bath to 2 parts. When cold, add the alcohol, set the mixture aside for 12 hours, filter, and add sufficient simple syrup to the filtrate to bring the weight of the product up to 20 parts.—P. G.

Uses.—This syrup is extensively employed to mask the taste of medicinal substances, particularly ammonium chloride and quinine salts. Its dose is 1 to 4 drachms (4–16 Cc.).

SYRUPUS GLUCOSI, *Br.*—Syrup of Glucose.

Sirop de glycose, Fr.; *Glykosesirup*, G.

Preparation.—Take of liquid glucose of commerce, 1 ounce; syrup, 2 ounces. Mix by the aid of gentle heat.—Br.

Uses.—Syrup of glucose is not intended to be used medicinally, but is serviceable as an excipient for pill-masses and similar preparations.

SYRUPUS HEMIDESMI, *Br.*—Syrup of Hemidesmus.

Sirop de hemidesmus, Fr.; *Hemidesmussirup*, G.

Preparation.—Take of hemidesmus-root, bruised, 4 ounces: refined sugar, 28 ounces; boiling distilled water, 1 pint (Imperial). Infuse the hemidesmus in the water, in a covered vessel, for 4 hours, and strain. Set the infusion aside until clear; then decant the clear liquor, add the sugar, and dissolve by means of a gentle heat. The product should weigh 2 pounds 10 ounces.—Br.

Uses.—The syrup of hemidesmus possesses no definite medicinal properties. It is used as a flavoring agent in the dose of 1 to 4 drachms (4–16 Cc.).

SYRUPUS HYPOPHOSPHITUM, *U. S.*—Syrup of Hypophosphites.

Syrupus calcii hypophosphitis compositus.—Sirop d'hypophosphite de chaux composé, Fr.; *Hypophosphitsirup*, G.

Preparation.—Calcium hypophosphite, 45 Gm.; potassium hypophosphite, 15 Gm.; sodium hypophosphite, 15 Gm.; diluted hypophosphorous acid, 2 Gm.; sugar, 650 Gm.; tincture of fresh lemon peel, 5 Cc.; water, a sufficient quantity to make 1000 Cc. Triturate the hypophosphites with 450 Cc. of water, until they are dissolved; add the tincture of fresh lemon peel and the hypophosphorous acid and filter the liquid. In the filtrate dissolve the sugar by agitation, without heat, and add enough water, through the filter, to make the product measure 1000 Cc. Strain if necessary.—U. S.

Syrup of hypophosphites may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under SYRUPUS. Pour the filtrate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate until it runs through clear, and when all the liquid has passed follow it by water until the product measures 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of the official syrup of hypophosphites use 330 grains of calcium hypophosphite, 110 grains each of potassium and sodium hypophosphite, 10 avoirdupois ounces and 390 grains of sugar, 1 fluidrachm of tincture of fresh lemon peel, 15 minims of diluted hypophosphorous acid, and 8 fluidounces of water. Each Cc. contains 0.075 Gm. or each teaspoonful nearly 4.3 grains of the combined hypophosphites, $\frac{3}{5}$ of the weight being calcium salt.

Uses.—This syrup may be given whenever the hypophosphites are indicated. The dose is 1 to 4 drachms (4–16 Cc.).

SYRUPUS HYPOPHOSPHITUM COMPOSITUS, *U. S.*—Compound Syrup of Hypophosphites.

Sirop des hypophosphites composé, Fr.; *Zusammengesetzter Hypophosphitsirup*, G.

Preparation.—Calcium hypophosphite, 35 Gm.; potassium hypophosphite, 17.5 Gm.; sodium hypophosphite, 17.5 Gm.; ferric hypophosphite, 2.25 Gm.; manganese hypophosphite, 2.25 Gm.; quinine, 1.1 Gm.; strychnine, 0.115 Gm.; sodium citrate, 3.75 Gm.; diluted hypophosphorous acid, 15 Cc.; sugar, 775 Gm.; water, a sufficient quantity to make 1000 Cc. Rub the ferric and manganese hypophosphites with the sodium citrate, add 30 Cc. of water, and warm the mixture for a few minutes until a clear greenish solution is obtained. Dissolve the calcium, potassium, and sodium hypophosphites in 450 Cc. of water, to which 5 Cc. of diluted hypophosphorous acid has previously been added; then dissolve the quinine and strychnine in 30 Cc. of water with the aid of 10 Cc. of diluted hypophosphorous acid, and finally dissolve the sugar, with agitation, in these solutions previously mixed. Strain the syrup if necessary, and add sufficient water, through the strainer, to make the product measure 1000 Cc.—U. S.

1 pint of compound syrup of hypophosphites may be prepared as follows: Rub 16½ grains each of ferric and manganese hypophosphites with 28 grains of sodium citrate, add ½ fluidounce of water, and warm the mixture until a clear greenish solution results. Dissolve 260 grains of calcium hypophosphite and 130 grains each of potassium and sodium hypophosphites in 7 fluidounces of water, to which 36 minims of diluted hypophosphorous acid have previously been added; then dissolve 8 grains of quinine and ⅞ grain of strychnine in ½ fluidounce of water with the aid of 80 minims of diluted hypophosphorous acid. Mix the three solutions and dissolve therein 13½ avoirdupois ounces of sugar, with agitation, strain, and add sufficient water to bring the volume of the syrup up to 16 fluidounces.

Compound syrup of hypophosphites is one of the new official preparations, although a very similar syrup has been in use for a number of years, the formula for which was available in the National Formulary. Each Cc. of the syrup contains 0.035 Gm. of calcium hypophosphite, 0.0175 Gm. each of potassium and sodium hypophosphites, 0.00225 Gm. each of ferric and manganese hypophosphites, 0.0011 Gm. of quinine, and 0.000115 Gm. of strychnine, or each fluidrachm contains about 2 grains of calcium hypophosphite, 1 grain each of potassium and sodium hypophosphites, ⅛ grain each of ferric and manganese hypophosphites, $\frac{1}{176}$ grain of quinine, and $\frac{1}{1416}$ grain of strychnine.

Uses.—This preparation is an efficient tonic and reconstructive in struma, scrofula, rickets, secondary anæmia, and other debilitated states. It has no specific action in tuberculosis, and is of value in this disease simply to improve the appetite and digestion and correct the anæmia. It is given in the dose of 1 to 4 drachms (4–16 Cc.).

SYRUPUS IPECACUANHÆ, *U. S.*—Syrup of Ipecac.

Sirupus ipecacuanhæ, P. G.—*Sirop d'ipécacuanha*, Fr.; *Brechwurzelsirup*, G.

Preparation.—Fluidextract of ipecac, 70 Cc.; acetic acid, 10 Cc.; glycerin, 100 Cc.; sugar, 700 Gm.; water, a sufficient quantity to make 1000 Cc. Dilute the fluidextract of ipecac with 300 Cc. of water to which the acetic acid has previously been added, and mix them thoroughly by shaking; set the liquid aside for 24 hours. Then filter, and pass enough water through the filter to obtain 450 Cc. of filtrate. To this add the glycerin; dissolve the sugar in the liquid, and add enough water to make the product measure 1000 Cc. Mix thoroughly, and strain if necessary.—U. S.

Syrup of ipecac may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under SYRUPUS. Mix the filtrate obtained as directed in the preceding formula with the glycerin, pour the mixture upon the sugar, return the first portions of the percolate until it runs through clear, and when all the liquid has passed follow it by water until the product measures 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of ipecac add 9 fluidrachms of fluidextract of ipecac to a mixture of 4½ fluidounces of water and 75 minims of acetic acid; shake well, filter, and wash filter with sufficient water to obtain 7 fluidounces of filtrate. To this add 1½ fluidounces of glycerin, 12 avoirdupois ounces of sugar, and sufficient water to bring the volume up to 16 fluidounces.

The present official formula, which is identical with that of 1890, aims at obtaining a perfect aqueous solution of the active virtues of ipecac by treating the fluidextract with very dilute acetic acid; the addition of 10 per cent., by volume, of glycerin will prevent subsequent changes in the syrup. Each Cc. represents the activity of 0.070 Gm. of ipecac, or each fluidrachm equals about 4 grains.

The syrup of the German Pharmacopœia represents 1 per cent. of its weight of ipecacuanha root, and that of the French Codex 1 per cent. of extract of ipecacuanha.

Uses.—Syrup of ipecac is the most frequently employed preparation of the drug. Its emetic dose to a child 2 to 4 years of age is from ½ to 1 drachm (2–4 Cc.); to an adult, ½ to 1 ounce (16–30 Cc.), repeated every 10 to 15 minutes until it acts. As an expectorant, its dose is 20 to 60 minims (1.30–4 Cc.) to an adult, and 2 to 10 minims (0.10–0.60 Cc.) to a child.

Allied Preparation.—SYRUPUS IPECACUANHÆ COMPOSITUS.—*Sirop d'ipécacuanha composé*, Fr. Cod.; *Compound syrup of ipecac*, E.; *Sirop de Desessartz*, Fr.—Take of ipecac root, moderately fine powder, 30 Gm.; senna leaves, 100 Gm.; wild thyme, 30 Gm.; poppy flowers, 125 Gm.; magnesium sulphate, 100 Gm.; white wine, 750 Gm.; orange flower water, 750

Gm.; boiling distilled water, 3000 Gm.; sugar, a sufficient quantity. Macerate the ipecac and senna in the white wine for 12 hours; express and filter. To the residue add the wild thyme and poppy flowers, pour the boiling water over the mixture and infuse during 6 hours, and then express. To the strained liquid add the magnesium sulphate and the orange flower water. Filter, and add the vinous liquid previously prepared, and for every 100 Gm. of liquid add 180 Gm. of sugar. Dissolve by heating on a water-bath.—Fr. Cod.

SYRUPUS KRAMERIÆ, *U. S.*—Syrup of Krameria.

Syrupus ratanhiæ.—Syrup of rhatany, E.; *Sirop de ratanhia*, Fr.; *Ratanhiasirup*, G.

Preparation.—Fluidextract of krameria, 450 Cc.; syrup, 550 Cc. to make 1000 Cc. Mix them.—U. S.

Each fluidounce of the official syrup contains 216 minims of fluidextract of rhatany, or 27 minims in each teaspoonful (fluidrachm).

Uses.—Syrup of krameria is chiefly used as a remedy in diarrhœa, and is usually combined with antacids and other astringents. Its dose is from 30 to 60 minims (2–4 Cc.) to a child, and ½ ounce (16 Cc.) to an adult.

SYRUPUS LACTUCARII, *U. S.*—Syrup of Lactucarium.

Sirop de lactucarium, Fr.; *Lactucariumsirup*, G.

Preparation.—Tincture of lactucarium, 100 Cc.; glycerin, 200 Cc.; citric acid, 1 Gm.; orange flower water, 50 Cc.; syrup, a sufficient quantity to make 1000 Cc. Mix the tincture of lactucarium with the glycerin, add the orange flower water, in which the citric acid has been dissolved, and filter, if necessary. Finally, add a sufficient quantity of syrup to make the product measure 1000 Cc.—U. S.

To make 1 pint of syrup of lactucarium mix 1 fluidounce and 288 minims of tincture of lactucarium with 3 fluidounces and 96 minims of glycerin, and add 384 minims of orange flower water in which 8 grains of citric acid have been previously dissolved. Filter if necessary, and add sufficient syrup to bring the volume up to 16 fluidounces

The present official formula is an improvement on that of the 1890 Pharmacopœia, and if the tincture of lactucarium has been carefully made so as to be free from the caoutchouc-like constituent of the drug, the resulting syrup should be clear and of a light brownish color. The addition of citric acid and orange flower water materially improves the taste of the syrup. It represents the virtues of 0.05 Gm. of lactucarium in each Cc., or about 3 grains in each fluidrachm.

Sirop de lactucarium opiacé, Fr. Cod., contains in each tablespoonful 0.005 Gm. ($\frac{1}{14}$ grain) of extract of opium and 0.01 Gm. ($\frac{1}{7}$ grain) of alcoholic extract of lactucarium.

Uses.—In the dose of 2 to 4 drachms (8–16 Cc.), syrup of lactucarium is a sedative of uncertain value.

SYRUPUS LIMONIS, *Br.*—Syrup of Lemon.

Syrupus succi citri.—Sirop de suc de limon (de citron), Fr.; *Citronensirup*, G.

Preparation.—Fresh lemon peel, in thin slices or grated, 1 ounce; alcohol (90 per cent.), a sufficient quantity; lemon juice, 25 fluidounces; refined sugar, 38 ounces. Macerate the lemon peel in 1½ fluidounces of the alcohol for 7 days; press; filter; add sufficient of the alcohol to produce 2 fluidounces. In the lemon juice, clarified by subsidence, dissolve the refined sugar by the aid of a gentle heat. When the resulting syrup is cold, mix with it the 2 fluidounces of alcoholic liquid. The product should weigh 4 pounds and 1 ounce.—Br.

Uses.—This syrup is used as a vehicle, and, diluted with carbonated water, forms a grateful drink in febrile affections.

SYRUPUS MANNÆ.—Syrup of Manna.

Sirupus mannæ, P. G.—*Sirop de manne*, Fr.; *Mannasirup, G.*

Preparation.—Manna, 10 parts; alcohol, 2 parts; water, 33 parts; sugar, 55 parts. Dissolve the manna in the water, to which the alcohol has previously been added, filter

the solution, and to the filtrate add the sugar and dissolve with the aid of a moderate heat.—P. G.

Syrup of manna has a yellowish color and a characteristic sweet taste.

Uses.—Syrup of manna is mildly laxative. Its dose is 2 to 8 drachms (8–30 Cc.).

SYRUPUS MENTHÆ PIPERITÆ.—Syrup of Peppermint.

Sirupus menthæ, P. G.—*Sirop de menthe poivrée*, Fr.; *Pfefferminzsirup*, G.

Preparation.—Peppermint leaves, in moderately fine powder, 2 parts; alcohol, 1 part; water, 10 parts; sugar, 13 parts. Moisten the peppermint leaves with the alcohol, add the water and macerate at ordinary room-temperature for 24 hours, stirring the mixture repeatedly. Express, filter the liquid, and in 7 parts of the filtrate dissolve the sugar with the aid of a gentle heat.—P. G.

Syrup of peppermint is of a greenish-brown color, and possesses the characteristic odor and taste of the drug.

Uses.—This syrup is used as an agreeable flavoring agent.

SYRUPUS PAPAVERIS.—Syrup of Poppies.

Sirupus papaveris, P. G.—*Syrupus capitum papaveris, Syrupus diacodii.—Sirop de pavot blanc*, Fr.; *Mohnsirup*, G.

Preparation.—Poppy capsules, in moderately fine powder, 10 parts; alcohol, 7 parts; water, 70 parts; sugar, 65 parts. Moisten the powder with the alcohol, add the water and macerate for 24 hours, at ordinary room-temperature, with frequent stirring. Express the mixture, heat the liquid to the boiling-point, evaporate to 35 parts and filter. In the filtrate, dissolve the sugar with the aid of moderate heat, and add sufficient water to the syrup, when cold, to bring the total weight up to 100 parts. Mix thoroughly.—P. G.

The French Codex directs that 1 part of an extract of poppy capsules, made with 60 per cent. alcohol, be dissolved in 3 parts of alcohol (60 per cent.), and this solution added to 96 parts of simple syrup.

Uses.—Because of the uncertain morphine strength of this preparation, it is inadvisable to employ it. Its dose is stated to be ½ drachm (2 Cc.).

SYRUPUS PICIS LIQUIDÆ, *U. S.*—Syrup of Tar.

Sirop de goudron, Fr. Cod.; *Syrupus cum aquâ piceâ; Syrupus piceus.—Theersirup*, G.

Preparation.—Tar, 5 Gm.; alcohol, 50 Cc.; magnesium carbonate, 10 Gm.; sugar, 850 Gm.; water, a sufficient quantity. Mix the tar intimately, in a mortar, with 10 Gm. of clean white sand, add 100 Cc. of water, and, after kneading the mass thoroughly with the pestle, pour off the water and throw it away. Treat the residue with the alcohol, and, when the tar is dissolved, add the magnesium carbonate and 50 Gm. of sugar, and after thorough trituration add 400 Cc. of water; stir the mixture occasionally during 2 hours, and filter. Dissolve the remainder of the sugar in the clear filtrate by means of gentle heat, strain, and add sufficient water to make the product measure 1000 Cc.—U. S.

To make 1 pint of syrup of tar, mix 30 grains of tar with 75 grains of clean sand, add 1½ fluidounces of water, knead well and throw the liquid away. Treat the residue with 5½ fluidrachms of alcohol, and, when the tar is dissolved, add 75 grains of magnesium carbonate and 400 grains of sugar, triturate well, and add 6 fluidounces of water; stir the mixture occasionally during 2 hours, filter, and in the clear filtrate dissolve 13 avoirdupois ounces of sugar with the aid of heat; finally add sufficient water to bring the volume up to 16 fluidounces.

This formula differs somewhat from that of the 1890 Pharmacopœia. The tar is first treated with water for the purpose of removing most of the acetic acid present, and this infusion is rejected. The various soluble constituents of tar are then extracted by a weak hydroalcoholic menstruum; in the solution thus obtained the sugar is dissolved. Thus prepared, the syrup is of a yellowish color, has the odor of tar, a slightly bitter taste and an acid reaction, and when rendered alkaline becomes brown.

SYRUPUS PICIS IODATUS, *Sirop de goudron iodé*, is much employed in France, and

contains $\frac{1}{10}$ per cent. of iodine. 1 grain of iodine dissolved in a little alcohol is added, with agitation, to 1000 grains of syrup of tar; the color of iodine will disappear in a few days, when the iodized syrup has about the same color as tar syrup.

Uses.—The present formula perhaps affords a slightly more efficient product than that in the Pharmacopœia of 1890, and may be used when tar is indicated. The dose is from 1 to 4 drachms (4–16 Cc.).

SYRUPUS PRUNI VIRGINIANÆ, *U. S., Br.*—Syrup of Wild Cherry.

Syrup of Virginian prune, Br.; *Sirop d'écorce de cerisier*, Fr.; *Wildkirschenrindensirup*, G.

Preparation.—Wild cherry, in No. 20 powder, 150 Gm.; sugar, 700 Gm.; glycerin, 150 Cc.; water, a sufficient quantity to make 1000 Cc. Moisten the wild cherry with a sufficient quantity of water, and macerate for 24 hours in a covered vessel; introduce the glycerin into a graduated receiving bottle; pack the wild cherry firmly in a cylindrical percolator, and gradually pour water upon it; continue the percolation (shaking the percolate occasionally with the glycerin), until the liquid measures 450 Cc. Dissolve the sugar in the liquid by agitation, without heat, strain, and pass enough water through the strainer to make the product measure 1000 Cc. Mix thoroughly.—U. S.

Syrup of Wild Cherry may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under SYRUPUS. Pour the percolate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by water until the product measures 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of wild cherry bark use $2\frac{1}{2}$ avoirdupois ounces of the ground bark, and after maceration collect enough percolate to measure, with addition of $2\frac{1}{2}$ fluidounces of glycerin, $7\frac{1}{2}$ fluidounces. In this liquid dissolve 12 avoirdupois ounces of sugar and add sufficient water to bring the volume up to 16 fluidounces.

The formula of the British Pharmacopœia is practically identical with the above, except that the finished syrup contains a little more sugar and somewhat less than half as much glycerin as that of the U. S. P.

The treatment of wild cherry bark with cold water results in the production of hydrocyanic acid and oil of bitter almonds, which, together with the bitter and astringent principles, are contained in the syrup, which has a rich brownish-red color and a pleasant taste.

Enough menstruum should be added to the powder to thoroughly moisten it, and the vessel be kept tightly closed to prevent loss of hydrocyanic acid: a No. 20 powder being rather coarse, the mixture must be very firmly packed and the percolation be allowed to go on in slow drops, so as to ensure exhaustion of the bark. The present syrup is of much lighter color and less astringent taste than the syrup of 1890, due to the fact that the glycerin is not added to the water before percolation, but subsequently to the aqueous percolate. The syrup keeps well ordinarily, but in summer time should be stored in a cool place.

Uses.—Syrup of wild cherry is used for its pleasant taste and mildly sedative properties as a vehicle in expectorant mixtures. Its dose is from 1 to 4 drachms (4–16 Cc.).

SYRUPUS RHAMNI CATHARTICÆ.—Syrup of Buckthorn.

Sirupus rhamni catharticæ, P. G.; *Syrupus spinæ cervinæ.—Sirop de nerprun*, Fr.; *Kreuzdornbeerensirup*, G.

Preparation.—Fresh buckthorn-berries are mashed and allowed to ferment at 20° C. (68° F.) in a covered vessel, until 2 volumes of the filtered liquid mix clear with 1 volume of alcohol; the juice is then expressed, and in it sugar is dissolved in the proportion of 13 parts for every 7 parts by weight of juice.—P. G.

Uses.—In Europe this syrup is used as a purgative for children in the dose of 1 drachm (4 Cc.).

SYRUPUS RHEI, *U. S., Br.*—Syrup of Rhubarb.

Sirupus rhei, P. G.—*Sirop de rhubarbe*, Fr.; *Rhabarbersaft*, G.

Preparation.—Fluidextract of rhubarb, 100 Cc.; spirit of cinnamon, 4 Cc.; potassium carbonate, 10 Gm.; water, 50 Cc.; syrup, a sufficient quantity to make

1000 Cc. Mix the spirit of cinnamon with the fluidextract of rhubarb, and add to it the potassium carbonate dissolved in the water. Then add enough syrup to make the product measure 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of rhubarb use 1½ fluidounces and 48 minims of fluidextract of rhubarb, 30 minims of spirit of cinnamon, 73 grains of potassium carbonate, 388 minims of water, and sufficient syrup.

Take of rhubarb-root, in No. 20 powder, coriander-fruit, in No. 20 powder, each 2 ounces; refined sugar, 24 ounces; alcohol (90 per cent.), 8 fluidounces; distilled water, 24 fluidounces. Mix the rhubarb and coriander; moisten with a portion of the mixed alcohol and water, and set aside; pack them in a percolator; pass the remainder of the diluted alcohol slowly through them; evaporate the liquid that has thus passed until it is reduced to 14 fluidounces, and in this, after it has been filtered, dissolve the sugar with the aid of heat. The product should weigh nearly 2½ pounds.—Br.

The U. S. P. syrup of rhubarb is nearly twice as strong as that of the British and German Pharmacopœias, both of the latter representing only 5 per cent. by weight of rhubarb.

The present syrup is of a deep brown-red color, and is transparent in thin layers; the presence of alkali renders it unfit for combination with various salts, which are precipitated thereby. The syrup of the Br. P. is of a deep-brown color and somewhat opaque.

Uses.—Syrup of rhubarb, though rarely used, may be given as a cathartic to infants in the dose of 1 drachm (4 Cc.).

SYRUPUS RHEI AROMATICUS, *U. S.*—Aromatic Syrup of Rhubarb.

Spiced syrup of rhubarb, E.; *Sirop de rhubarbe aromatique*, Fr.; *Gewürzter Rhabarbersaft*, G.

Preparation.—Aromatic tincture of rhubarb, 150 Cc.; potassium carbonate, 1 Gm.; syrup, 850 Cc. to make 1000 Cc. Dissolve the potassium carbonate in the aromatic tincture of rhubarb. Filter if necessary, and add sufficient syrup to make the product measure 1000 Cc. Mix.—U. S.

To make 1 pint of aromatic syrup of rhubarb, dissolve 8 grains of potassium carbonate in 2½ fluidounces of aromatic tincture of rhubarb, and mix the solution with 13½ fluidounces of simple syrup.

The present official syrup differs from that of the 1890 Pharmacopœia in containing a small quantity of potassium carbonate, whereby a clearer mixture is produced. It has a rich reddish-brown color, an agreeable odor, and a spicy and bitterish but pleasant taste.

Uses.—The aromatic syrup is the most extensively employed preparation of rhubarb. It is used with marked benefit for its primary laxative action and its after-constipating effect in the diarrhœas of infants and children due to indigestion and intestinal fermentation in the dose of 1 to 2 drachms (4–8 Cc.).

SYRUPUS RHŒADOS, *Br.*—Syrup of Red Poppy.

Sirop de coquelicot, Sirop de pavot rouge, Fr.; *Klatschrosensaft*, G.

Preparation.—Take of red-poppy petals, 13 ounces; refined sugar, 2½ pounds; distilled water, 1 pint (Imperial), or a sufficiency; alcohol (90 per cent.) 2½ fluidounces. Add the petals gradually to the water heated in a water-bath, frequently stirring, and afterward, the vessel being removed, infuse for 12 hours. Then press out the liquor, strain, add the sugar, and dissolve by means of heat. When nearly cold add the alcohol and as much distilled water as may be necessary to make up for loss in the process, so that the product shall weigh 3 pounds 10 ounces.—Br.

The addition of alcohol to the finished syrup is designed to counteract its tendency to fermentation. The syrup is of a deep-red color.

Uses.—This preparation is of uncertain strength and rarely employed. The dose is stated to be 1 drachm (4 Cc.).

SYRUPUS ROSÆ, *U. S.*, *Br.*—Syrup of Rose.

Syrupus rosarum rubrarum.—Syrup of red rose, E.; *Sirop des roses rouges*, Fr.; *Rosensirup*, G.

Preparation.—Fluidextract of rose, 125 Cc.; diluted sulphuric acid, 10 Cc.; sugar, 750 Gm.; water, a sufficient quantity. Mix the fluidextract of rose and diluted sulphuric acid with 300 Cc. of water; after allowing the mixture to stand 2 hours, filter, and dissolve the sugar in the clear filtrate by agitation. Finally, add a sufficient quantity of water to make the product measure 1000 Cc. Strain if necessary.—U. S.

To make 1 pint of syrup of rose, add 2 fluidounces of fluidextract of rose and 73 minims of diluted sulphuric acid to 5 ounces of water, allow the mixture to stand 2 hours, filter, and in the filtrate dissolve 12½ avoirdupois ounces of sugar, adding sufficient water finally to bring the volume up to 16 fluidounces.

Take of dried red-rose petals, 2 ounces; refined sugar, 30 ounces; boiling distilled water, 1 pint. Infuse the petals in the water for 2 hours; strain with expression, heat the liquor to the boiling-point, and filter. Dissolve the sugar in the liquor by means of heat. The product should weigh 2 pounds 14 ounces.—Br.

The syrup is of a fine red color and has an agreeable acidulous somewhat astringent taste. Each fluidounce contains 1 fluidrachm of the fluidextract of red-rose petals.

Uses.—It is used to impart an agreeable flavor and color to other syrups and mixtures.

SYRUPUS RUBI, *U. S.*—Syrup of Rubus.

Syrup of blackberry-bark, E.; *Sirop d'écorce de ronce*, Fr.; *Brombeerrindensirup*, G.

Preparation.—Fluidextract of rubus, 250 Cc.; syrup, 750 Cc. to make 1000 Cc. Mix them.—U. S.

This syrup has a deep reddish-brown color and a strongly astringent taste. Each fluidounce contains 2 fluidrachms of the fluidextract.

Uses.—As a mild astringent this syrup is useful in serous diarrhœa in the dose of 1 to 2 drachms (4–8 Cc.).

SYRUPUS RUBI IDÆI.—Syrup of Raspberry.

Sirupus rubi idæi, P. G.—*Sirop de framboise*, Fr.; *Himbeersaft*, G.

Preparation.—Reduce the raspberries to a pulp, and let this stand, at a temperature of about 20° C. (68° F.), until a small portion of the filtered juice mixes clear with half its volume of alcohol. Then separate the juice by pressing, set it aside in a cool place until the liquid portion has become clear, and filter. To every 7 parts by weight of the filtrate add 13 parts of sugar, heat the mixture to boiling, and strain.—P. G.

Some care is necessary that the temperature during the fermentation of the fruit-pulp does not exceed that prescribed.

The French Codex directs the fresh fruit to be expressed and the juice to be fermented at a temperature of 12° to 15° C. (54–59° F.), fermentation to be arrested as soon as the liquid will readily pass through a filter; otherwise the flavor will be much impaired. Other fruit-juices are prepared in precisely the same manner. The juice of ripe raspberries ferments readily, and the fermentation is completed in a few hours or a day, according to the temperature. The formation of mould and acetic fermentation impair the flavor; the progress of fermentation should therefore be closely watched, and the expressed juice should be rapidly filtered and at once converted into syrup.

Properties.—Raspberry syrup has a bright-red color, a very agreeable fruit odor, a pleasant acidulous taste, and a distinct acid reaction. When agitated with amylic alcohol, ether, or chloroform, these liquids should not become colored. On being rendered alkaline the syrup becomes dark-blue or dingy-violet colored, and when treated with basic lead acetate a dingy-blue or blue-green precipitate is produced, the filtrate being colorless or nearly so. When strongly acidulated with cold nitric acid the red color is not changed to yellow. These reactions serve to distinguish raspberry syrup from imitations colored with aniline red or with other coloring matters of vegetable origin.

Uses.—This, like all other fruit syrups, is used as a palatable vehicle for other drugs, and diluted with water it is a refreshing drink in febrile conditions.

SYRUPUS SARSAPARILLÆ COMPOSITUS, *U. S.*—Compound Syrup of Sarsaparilla.

Syrupus sudorificus.—Sirop de salsepareille composé, Sirop sudorifique, Fr.; *Zusammengesetzter Sarsaparillsirup,* G.

Preparation.—Fluidextract of sarsaparilla, 200 Cc.; fluidextract of glycyrrhiza, 15 Cc.; fluidextract of senna, 15 Cc.; sugar, 650 Gm.; oil of sassafras, 0.2 Cc.; oil of anise, 0.2 Cc.; oil of gaultheria, 0.2 Cc.; water, a sufficient quantity to make 1000 Cc. Add the oils (equivalent to 4 drops each) to the mixed fluidextracts and shake the liquid thoroughly. Then add enough water to make up the volume to 600 Cc. and mix well. Set the mixture aside for 1 hour, then filter it. In the filtrate dissolve the sugar with the aid of a gentle heat, allow the liquid to cool, strain, and add enough water through the strainer to make the product measure 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of compound syrup of sarsaparilla mix 2 drops each of oils of gaultheria, anise, and sassafras with ¼ fluidounce each of fluidextracts of senna and glycyrrhiza, and 3¼ fluidounces of fluidextract of sarsaparilla; add sufficient water to make 9½ fluidounces, and after filtration dissolve 11 avoirdupois ounces of sugar in the filtrate, and add enough water to bring the volume up to 16 fluidounces.

The present official formula is identical with that of 1890, except that the quantity of volatile oils has been doubled.

The syrup of the French Codex is made by hot infusion of sarsaparilla, borage-flowers, pale rose, senna, and anise; it is known as *sirop de Cuisinier.* Under the name of *sirop de Laffecteur* and *rob Boyveau-Laffecteur* a similar but more complex preparation has been in use in France; more than 30 drugs entered into its composition.

Uses.—Compound syrup of sarsaparilla is wanting in active medicinal properties. It is a convenient vehicle for the administration of potassium iodide. Corrosive sublimate, which is sometimes dispensed in the syrup, is said to be converted into calomel. The dose of the syrup is from 1 to 4 drachms (4–16 Cc.).

SYRUPUS SCILLÆ, *U. S., Br.*—Syrup of Squill.

Syrupus aceti scillæ.—Sirop de scille, Fr.; *Meerzwiebelsirup,* G.

Preparation.—Vinegar of squill, 450 Cc.; sugar, 800 Gm.; water, a sufficient quantity to make 1000 Cc. Dissolve the sugar in the vinegar of squill with the aid of a gentle heat, then strain, and, when the strained liquid is cold, add enough water, through the strainer, to make the product measure 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of squill use 7½ fluidounces of vinegar of squill and 13½ avoirdupois ounces of sugar, finally adding sufficient water to bring the volume up to 16 fluidounces.

Syrup of squill should always be made in porcelain or glass vessels, and the use of metal avoided, on account of the acetic acid present. The syrup of the British Pharmacopœia is made by dissolving 38 ounces of sugar in 1 pint (20 fluidounces, Imperial) of vinegar of squill with the aid of heat, and the product should weigh 3 pounds and 10 ounces; hence it is slightly denser than the above preparation.

Uses.—This is the preparation of squill that is ordinarily used as an expectorant, and for such purpose is frequently combined with senega or ipecac. Its expectorant dose is from ½ to 1 drachm (2–4 Cc.), which, if repeated at short intervals, will act as an emetic.

SYRUPUS SCILLÆ COMPOSITUS, *U. S.*—Compound Syrup of Squill.

Sirup de scille composé, Fr.; *Zusammengesetzter Meerzwiebelsirup,* G.

Preparation.—Fluidextract of squill, 80 Cc.; fluidextract of senega, 80 Cc.; antimony and potassium tartrate, 2 Gm.; purified talc, 20 Gm.; sugar, 750 Gm.; water, a sufficient quantity to make 1000 Cc. Mix the fluidextracts, evaporate them, on a water-bath, in a tared capsule, to 100 Gm., and mix the residue with 350 Cc. of water. When the mixture is cold, incorporate with it, intimately, the purified talc, filter, pass enough water through the filter to obtain 400 Cc. of clear filtrate, and add to the filtrate the antimony and potassium tartrate, dissolved in 25 Cc. of hot water. In this liquid dissolve the sugar by agitation, without heat, strain, and add

enough water through the strainer to make the product measure 1000 Cc. Mix thoroughly.—U. S.

Compound Syrup of Squill may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under SYRUPUS. Pour the filtrate, obtained as directed in the preceding formula, and mixed with the solution of antimony and potassium tartrate, upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of compound syrup of squill mix 10¼ fluidrachms each of fluidextracts of squill and senega, evaporate to 1½ avoirdupois ounces, and add 5 fluidounces of water. When cold incorporate 150 grains of purified talc and filter, passing enough water through the filter to obtain 7 fluidounces of clear filtrate; to the filtrate add 15 grains of tartar emetic, dissolved in ½ ounce of hot water. In the mixed liquid dissolve 12½ avoirdupois ounces of sugar, and add enough water to bring the volume of the syrup up to 16 fluidounces.

After the evaporation of the alcohol in the official process considerable insoluble matter (pectin compounds) is apt to separate, which it is intended to remove by aid of purified talc; if necessary the liquid should be returned to the filter until it runs clear, and the solution of tartar emetic should not be added until a clear filtrate has been obtained. The finished syrup contains a little less than ⅛ grain of tartar emetic in each fluid drachm, and if carefully prepared it will keep well.

This syrup is known as *hive syrup* and *croup syrup*, and is an official substitute for *Coxe's hive syrup*, which was made by boiling the drugs in water and preserving the liquid by honey.

Uses.—The combination of squill, senega, and tartaric emetic imparts to this preparation expectorant, diaphoretic, emetic, and, in large doses, purgative properties. It was introduced into medicine as a remedy in spasmodic croup or "hives," which it relieves through the relaxation dependent upon the nausea caused by it in proper dose. As an expectorant it is of especial service when the bronchial secretion is scant. In croup 10 to 30 minims (0.60–2 Cc.) should be given every 10 to 15 minutes until its nauseant effect is developed. Its expectorant dose in adults is from 20 to 30 minims (1.30–2 Cc.).

SYRUPUS SENEGÆ, *U. S.*—Syrup of Senega.

Sirupus senegæ, P. G.; *Sirop de polygala*, Fr.; *Senegasirup*, G.

Preparation.—Fluidextract of senega, 200 Cc.; syrup, 800 Cc. Mix them.—U. S.

The present official formula differs from that of 1890 in directing the admixture of the fluidextract with syrup, and the syrup can be made extemporaneously or for stock by simply mixing 1 volume of the fluidextract with 4 volumes of syrup. Experience has shown that syrup of senega thus made keeps fully as well as when made by the former more tedious method. It is a clear reddish syrup, having the characteristic odor of senega and a decidedly acrid taste.

The syrup of senega of the German Pharmacopœia is made by dissolving 12 parts of sugar in 8 parts of a weakly alcoholic tincture of senega, representing about 1 part of the drug, and hence is of about ¼ the strength of the above syrup.

Uses.—Syrup of senega is useful as an expectorant in subacute and chronic bronchitis in the dose of 1 to 2 drachms (4–8 Cc.).

SYRUPUS SENNÆ, *U. S., Br.*—Syrup of Senna.

Sirupus sennæ, P. G.—*Sirop de séné*, Fr.; *Sennasirup*, G.

Preparation.—Fluidextract of senna, 250 Cc.; oil of coriander, 5 Cc.; syrup, a sufficient quantity to make 1000 Cc. Mix the oil of coriander with the fluidextract of senna and add a sufficient quantity of syrup to make the product measure 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of senna add 38 minims of oil of coriander to 4 fluidounces of fluidextract of senna and mix this with sufficient syrup to bring the volume up to 16 fluidounces.

The British Pharmacopœia directs that 40 ounces of senna be exhausted with 20 per cent. alcohol and the extract concentrated to 40 fluidounces; in this liquid 50 avoirdupois ounces of sugar are dissolved with the aid of heat, and when cool 10 minims of oil of coriander dissolved in 40 minims of 90 per cent. alcohol are added, and the whole well shaken. The finished product should weigh 5 pounds 12 ounces.

Syrup of senna of the German Pharmacopœia is made by macerating 10 parts of senna and 1 part of fennel with a mixture of 5 parts of alcohol and 60 parts of water for 12 hours, and then expressing. The liquid is heated to the boiling point and allowed to cool. To every 35 parts of the liquid 65 parts of sugar are added and dissolved with the aid of a gentle heat.

The present official syrup of senna is not identical with the syrup of 1890, being made with a fluid extract prepared from senna previously deprived of resinous and other matter soluble in 95 per cent. alcohol; hence the syrup is far less apt to cause griping.

Uses.—Syrup of senna is a gentle cathartic for children in the dose of ½ to 2 drachms (2–8 Cc.). To adults about twice this quantity should be given.

SYRUPUS TOLUTANUS, *U. S., Br.*—Syrup of Tolu.

Sirop de baume de tolu, Sirop balsamique, Fr.; *Tolubalsamsirup,* G.

Preparation.—Tincture of tolu, 50 Cc.; magnesium carbonate. 10 Gm.; sugar, 820 Gm.; water, a sufficient quantity to make 1000 Cc. Rub the tincture of tolu in a mortar with the magnesium carbonate and 60 Gm. of sugar. Then gradually add 450 Cc. of water, with constant trituration, and filter. Dissolve the remainder of the sugar in the clear filtrate with the aid of a gentle heat, strain the syrup while hot, and add a sufficient quantity of water to make the product measure 1000 Cc.—U. S.

Syrup of tolu may also be made in the following manner: Prepare a percolator or funnel in the manner described under SYRUPUS. Pour the filtrate, obtained as directed in the preceding formula, upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by water until the product measures 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of tolu mix 385 minims of tincture of tolu with 75 grains of magnesium carbonate and 1 ounce of sugar, add gradually 7 fluidounces of water and filter. In the filtrate dissolve 13 avoirdupois ounces of sugar, strain, and add sufficient water to bring the volume up to 16 fluidounces.

Take of balsam of tolu 1¼ ounces; refined sugar, 2 pounds; distilled water, 1 pint or a sufficiency. Boil the balsam in the water for half an hour in a tightly-covered vessel, stirring occasionally. Then remove from the fire, and add distilled water, if necessary, so that the liquid shall measure 16 ounces. Filter the solution when cold, add the sugar, and dissolve with the aid of a steam- or water-bath. The product should weigh 3 pounds.—Br.

Uses.—This syrup is used as an agreeable addition to expectorant mixtures. Its dose is 1 to 4 drachms (4–16 Cc.).

SYRUPUS ZINGIBERIS, *U. S., Br.*—Syrup of Ginger.

Sirup de gingembre, Fr.; *Ingwersirup,* G.

Preparation.—Fluidextract of ginger, 30 Cc.; alcohol, 20 Cc.; magnesium carbonate, 10 Gm.; sugar, 820 Gm.; water, a sufficient quantity to make 1000 Cc. Mix the fluidextract of ginger and the alcohol, then triturate the liquid in a mortar with the magnesium carbonate and 60 Gm. of sugar. Then gradually add 450 Cc. of water, with constant trituration, and filter. Dissolve the remainder of the sugar in the clear filtrate with the aid of a gentle heat, strain the syrup while hot, and add a sufficient quantity of water to make the product measure 1000 Cc.—U. S.

Syrup of ginger may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under SYRUPUS. Pour the filtrate, obtained as directed in the preceding formula, upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by water until the product measures 1000 Cc. Mix thoroughly.—U. S.

To make 1 pint of syrup of ginger mix ½ fluidounce of fluidextract of ginger with 160 minims of alcohol and triturate the mixture with 75 grains of magnesium carbonate and 1 ounce of sugar; add gradually 7 fluidounces of water and filter. In the filtrate dissolve 13 avoirdupois ounces of sugar, strain, and add sufficient water to bring the volume up to 16 fluidounces.

The syrup of the British Pharmacopœia is milky; it is made by mixing strong tincture of ginger, 1 fluidounce, representing ½ avoirdupois ounce of ginger, with syrup 19 fluidounces.

Uses.—Syrup of ginger is largely employed as a flavoring agent of mixtures, especially those given for their purgative effect and for the relief of abdominal colic. Its dose is 1 to 4 drachms (4–16 Cc.).

T.

TABACUM.—Tobacco; Leaf Tobacco.

Folia nicotianæ, P. G.; *Tabaci folia.—Tabac, Feuille de nicotiane*, Fr.; *Tabak*, G.; *Folha de Nicociana, Herva do Tabaco, Herva Santa*, Port.; *Hoja de Nicociana*, Sp.

The commercial dried leaves of *Nicotiana Tabacum* L. (*N. Havanensis* Lag.—Fam. *Solanaceæ*).

Tobacco has been official in most pharmacopœias, but is now discarded from all the leading ones. One or two specify the green leaves, while most stipulate that the dried leaves are not to be otherwise treated than by drying.

Origin.—The plant named in the definition is a native of tropical America, and is now cultivated in all parts of the world having a suitable climate, cold-temperate and very dry climates not being suitable therefor. Although official definitions named *N. Tabacum*, several other species are considerably cultivated for commercial tobacco, especially the following, here given in the order of their importance: *N. rustica* L., native of Mexico, and yielding most of the East Indian tobacco; *N. alata* Link et Otto (*N Persica* Lindl.), of Brazil, considerably cultivated in Cuba; *N. repanda* Willd., of Mexico. It would be a very difficult problem to determine the proportional yield of the different species, but it is probable that *N. Tabacum* yields at least half of the three or four million tons annually produced. Horticulture has done comparatively little in the development of hybrids and new forms of the tobacco plants. *N. Tabacum* is a tall, stout, glandular-hairy herb, with enormous leaves, annual or perennial according to the country in which it grows. It requires a very rich and highly fertilized soil. The production of flowers and seeds is prevented as far as practicable by cutting off the tops. Usually, the entire leafy stem is gathered and hung up to dry with the tops downward, the drying requiring several weeks, and the leaves losing about 80 per cent. in weight. This operation is recognized as one of "curing" rather than of simple drying, and there are many variations in the details. Artificial heat may or may not be employed, and in some instances the smoke resulting is supposed to play an important part in developing special flavors. These are also supposed to depend to a considerable extent upon the particular bacteria which are active during the process in different countries. After curing, the leaves are removed from the stems, carefully assorted as to size and quality, gathered into little bundles called "hands," and packed, chiefly in hogsheads, for marketing.

Description.—From 15 to 50 Cm. (6 to 20 In.) long and a third to a half as broad, oval to ovate or slightly obovate, contracted at the base into a long, broad, margined petiole, acute, entire, thin, with stout and prominent midrib and principal veins, more or less hairy, of variable, and usually mottled, shades of brown; odor very heavy, narcotic, and peculiar; taste bitter, acrid, and nauseous,

For commercial purposes the petiole and sindrib are removed and marketed as *Tobacco-stems;* but the definition, formerly official, requires the use of all of the leaf for medicinal purposes. The powdered stems are very largely employed as an insecticide, especially in horticulture, and commercial powdered tobacco frequently consists wholly or chiefly of this product. Numerous adulterants are employed.

Constituents.—An important consideration in the composition of tobacco is the localization of the different constituents in different parts of the leaf. Another is the changes produced by curing and in the manner of use, especially in smoking. Tobacco contains a large amount of salts, consisting of sulphates, nitrates, chlorides, phosphates, and malates of potassium, calcium, and ammonium, and it yields from 14 to 18.5 per cent. of ash. Larger amounts have been obtained, sometimes as much as 25 to 27 per cent.—a result which is doubtless due in some cases to dust adhering to the viscid glands. Flückiger found 10 per cent. of potassium nitrate, existing chiefly in the petiole and midrib. The malate of potassium is supposed to favor the "burning" of smoking tobacco, and when this is imperfect, it may be improved by the addition of a soluble salt of potassium, especially the acetate or nitrate. The other constituents of tobacco are

albumen, resin, gum, sugar, tannin, extractive, citric acid, nicotianin, and nicotine. *Nicotianin* or *Tobacco-camphor* is supposed to be chiefly responsible for the aroma or flavor of tobacco. It separates from the aqueous distillate in the form of white foliaceous crystals, which have an odor resembling that of tobacco-smoke and a warm, aromatic, and bitterish taste. Landerer (1835) obtained nicotianin from the dried, but not from the fresh, leaves.

Nicotine or *nicotia* is the poisonous principle of tobacco, and was discovered by Posselt and Reimann (1828). De Toni found it confined almost wholly to the epidermal tissue, and especially at the base of the hairs. It occurs in the cortical tissue of the root of the mature plant, especially just under the epidermis, and in the stamens and pistil, but not in the seed nor in the young plant. He regards it as non-protective, and the result of the reduction of oxygenous substances. He found the best tests for it to be with double iodide of potassium and mercury, iodized iodide of potassium, tannic acid, tetrachloride of platinum and of gold, iodized iodic acid, and Dragendorff's reagent.

The percentage of nicotine is extremely variable, from less than 1 to more than 10 per cent., and the conditions of its variation are but imperfectly known. As a general thing a hot, moist climate and rich soil favor an increase in the production of nicotine. The percentage of this and of nicotianin appear to vary inversely to one another, hence the importance of blending tobaccos in order to secure both "strength" (nicotine content) and flavor or aroma. Owing to the superficial location of the nicotine, it is very easily lost in careless drying, and the percentage is supposed to be ordinarily greatly reduced in this process. Some of the methods of curing, by burying in the earth, etc., doubtless result in a high nicotine content because of the prevention of loss in this way. Cox reports the average percentages in different products as follows: Syrian, 1 to 2; Manilla and Havana, 1 to 3; Virginian and Kentucky, up to 7; French (and Algerian), up to 9. Nicotine may be prepared by exhausting bruised tobacco with acidulated water, concentrating the infusion, adding an excess of potassa, and agitating with ether, which dissolves the alkaloid, and on the addition of powdered oxalic acid nicotine oxalate, which is insoluble in ether, is separated (Schloesing); or, the ether is evaporated, the liquid neutralized with oxalic acid, evaporated to dryness, and the residue exhausted with boiling alcohol, which dissolves nicotine oxalate (Ortigosa). On evaporating the solution to a syrupy consistence and agitating it with potassa and ether, an ethereal liquid is obtained, which on fractional distillation yields the alkaloid. This is a colorless oily liquid, having at 15° C. (59° F.) the specific gravity 1.0111, and remaining liquid at —10° C. (14° F.). It has an unpleasant, and when heated a pungent, acrid, tobacco-like odor, a burning taste, and a strongly alkaline reaction. Exposed to air and light, it rapidly acquires a brown color and is partly converted into a resinous compound. It boils near 250° C. (482° F.), but distils at a lower temperature, always leaving a residue. Its composition is $C_{10}H_{14}N_2$ (molecular weight, 160.96). It absorbs water from the air, dissolves readily in water, and is separated from this solution by caustic potassa. Alcohol and ether dissolve it in all proportions, and it yields with acids neutral and acid salts, of which the former crystallize with difficulty and are mostly soluble in weak alcohol, but insoluble in ether. The alkaloid acquires a wine-red color with strong sulphuric acid, and on heating the mixture is charred. Chlorine gas colors it deep-red or red-brown. When heated with a little hydrochloric acid a violet color is produced, which on the further addition of nitric acid changes to yellowish-red. The double salts with mercuric and platinic chloride are sparingly soluble in cold water.

The narcotic constituents of tobacco-smoke are as yet very imperfectly known. The volatile character of nicotine presupposes that certain amounts of it will appear in the smoke, even though it may be mostly destroyed, a supposition borne out by the experiment of collecting it in water through which the smoke is passed. A larger amount is volatilized and drawn into the mouth of the smoker, or condensed on its way there. Kissling believed the toxic action of tobacco-smoke to be chiefly due to nicotine, but Vahl and Eulenburg found chiefly *collidine*, *pyridine*, *picoline*, and other bases of the same series, besides ammonia and traces of *ethylamine;* and, in passing the vapors through potassium hydroxide solution, hydrocyanic, hydrosulphuric, acetic, formic, butyric, valerianic, carbolic, and probably other acids, were retained. Thoms obtained from the smoke a very poisonous oily substance, which produced violent headache, trembling, and giddiness. Its chief part boils between 220° and 230° C. (428° to 446° F.). By treatment with 2 per cent. potassium hydroxide solution, a phenol-like

body may be separated, which has an odor resembling creosote and boils at 190° to 200° C. (374° to 392° F.). It thus appears that not too much reliance should be placed upon the properties and presence of nicotine in determining the injurious effects of tobacco-smoking. Fruit fumigated with tobacco-smoke has been found to collect an oily coating which is very poisonous.

Pharmaceutical Preparations.—Although no longer official, both an ointment and a wine of tobacco were at one time recognized in the U. S. P. The former was made by incorporating an aqueous extract made from ½ ounce of tobacco with 8 ounces of lard. Wine of tobacco was made by exhausting 120 grains of tobacco with 4 fluidounces of white wine. When subjected to dry distillation, tobacco yields a brown-black, tar-like liquid of a strong and very peculiar empyreumatic odor. This was at one time (1870) officially recognized as *Oleum Tabaci*—Oil of Tobacco. Its composition is naturally very complex, and it is likely that some nicotine is present.

Action and Uses.—Tobacco is rarely employed to-day as a remedy except in domestic practice. It is a local irritant to mucous membranes, stimulating the secretions, increasing the flow of saliva when chewed, acting as a laxative when swallowed in small quantity, and as a purge in larger dose. Used in moderate amount, by being smoked, chewed, or snuffed by those who have acquired toleration to its influence, it produces a sense of mental and physical restfulness and well-being which has not been accounted for by studies of the physiological action of the crude drug or its alkaloid, nicotine. The effects of overdoses of tobacco, as usually manifested, consist in nausea and vomiting, quick, deep, and afterward labored respiration, great muscular relaxation, giddiness, mental confusion, restlessness, an enfeebled circulation, general depression, and occasionally clonic convulsions, followed by complete loss of reflexes and a fatal issue. The convulsions are considered to be of spinal origin, and death is due chiefly to paralysis of respiration, the heart continuing to pulsate after the cessation of breathing. The continuous over-indulgence in the use of tobacco results in chronic inflammation of the upper respiratory passages, indigestion, and loss of appetite. A condition known as "tobacco heart," characterized by cardiac irregularity and palpitation, frequently follows abuse of the drug. Headache, giddiness, tremors, and other nervous symptoms are of common occurrence. Certain eye symptoms, notably dimness of vision for colors, and even complete blindness, may occur. Examination of the eye-grounds in these cases reveals paleness of the retina in the milder type, and in the severe ones the optic nerve is found degenerated. Tobacco has been given internally to correct habitual constipation, and used in enemata to overcome impaction of feces and intestinal obstruction. As an antispasmodic, tobacco and nicotine were recommended in the treatment of laryngismus stridulus, asthma, hiccough, tetanus, and strychnine poisoning. Locally, an infusion and ointment have been applied with benefit in scabies, tinea, and other skin affections. Many cases of poisoning, some with fatal issue, have resulted from its external application, so that this use has been abandoned. Tobacco may be given as an emetic in the dose of 5 grains (0.30 Gm.), but is unsafe. The dose of nicotine is stated to be from $\frac{1}{60}$ to $\frac{1}{6}$ grain (0.001–0.01 Gm.).

Other Species.—The genus *Nicotiana* L. is credited with about 44 species, nearly all American. Several, besides those named above, yield commercial tobacco, and a number have been called species which are doubtless mere forms of others, especially of *N. Tabacum*. Others are known to be poisonous. A Mexican species grows rapidly as a small tree, resembling an alder or willow, and is planted for binding the shifting soil of the banks of rivers and canals. Its leaves are used in the South American Andes as a hypnotic.

TALCUM, *U. S., P. G.*—Talc.

Talcum venetum.—Soapstone, E.; *Talc, Talc de Vénise, Craie de Briançon*, Fr.; *Talk, Talkstein, Speckstein*, G.

A native hydrous magnesium silicate.—U. S.

Commercial native talc, although largely used for technical purposes, is not suitable for pharmaceutical work on account of the impurities present, and the Pharmacopœia, therefore, has very wisely recognized a purified article and given a method for preparing the same. The following properties are officially mentioned as belonging to native talc suitable for purification and subsequent use in pharmacy:

Properties and Test.—Talc is a white or grayish-white powder or grayish-green irregular masses of waxy lustre; when rubbed upon the skin it imparts a feeling like

greasiness; permanent in the air. Inodorous and tasteless. Insoluble in water, and in dilute solutions of the acids and alkali hydroxides. Specific gravity: 2.2 to 2.8. Mix 0.5 Gm. of talc with about 2 Gm. each of anhydrous sodium and potassium carbonates, heat the mixture in a platinum crucible until fusion is complete, and treat the resulting fused mass with hot water; then neutralize the liquid with diluted sulphuric acid, and, after adding an additional 10 Cc. of the latter, evaporate the mixture until the white fumes of sulphuric anhydride are evolved, then add 20 Cc. of water, and, after boiling the mixture and filtering, an insoluble residue of silica should be left. If to the filtrate ammonia-water and ammonium chloride test-solution be added, a white, gelatinous precipitate of aluminum hydroxide may be formed, while the filtrate from this, upon the addition of sodium phosphate test-solution, should yield a white, crystalline precipitate (magnesium). If 1 Gm. of talc be boiled with 25 Cc. of diluted hydrochloric acid for ½ hour, adding water from time to time to maintain approximately the original volume, and the liquid filtered, then the filtrate should yield, upon evaporating to dryness, igniting, and quickly weighing, not more than 0.05 Gm. of residue.—U. S.

TALCUM PURIFICATUM, *U. S.*—Purified Talc.

Talc purifié, Fr.; *Gereinigter Talk*, G.

Preparation.—Talc, in fine powder, 500 Gm.; hydrochloric acid, 75 Cc.; water, a sufficient quantity. Mix the powdered talc with about 2500 Cc. of boiling water, gradually add 50 Cc. of the hydrochloric acid, and boil the mixture during 15 minutes, then allow it to stand for 15 minutes. Decant, and reject the supernatant liquid containing the finer particles of talc in suspension, and again boil the residue with 2500 Cc. of water, mixed with the remainder of the hydrochloric acid, and allow it to stand for 15 minutes. Again decant and reject the finer suspended particles, and wash the coarser residue with water by repeated decantation, until a portion of the wash-water, after filtering and acidifying with nitric acid, fails to become opalescent upon the addition of silver nitrate test-solution. Then transfer the magma to a close linen or muslin strainer, allow it to drain, and dry it at 110° C. (230° F.).—U. S.

Properties and Test.—Purified talc, when subjected to ignition at red heat, should lose not more than 5 per cent. of its weight. If 10 Gm. of purified talc be boiled with 50 Cc. of distilled water for ½ hour, adding water from time to time to maintain approximately the original volume, it should yield a filtrate which is neutral to litmus-paper, and ½ of this filtrate, when evaporated and dried at 110° C. (230° F.), should yield not more than 0.005 Gm. of residue (limit of soluble substances). The remaining ½ of the filtrate, after slightly acidulating with hydrochloric acid, should not yield a blue color upon the addition of potassium ferrocyanide test-solution (absence of iron).—U. S.

The chief use to which purified talc is put in pharmacy is as a filtering medium, and for such purpose the powder should not be too fine, otherwise it will pass through the filter-paper and necessitate frequent pouring back of the filtrate. A No. 60 or perhaps 80 powder is far superior to the finer bolted varieties used for dusting purposes. It is absolutely essential that the washing with water be continued until all traces of hydrochloric acid have been removed.

Action and Uses.—Purified talcum is an excellent dusting-powder to allay the itching of prickly heat and other pruritic skin diseases. It forms the base of many cosmetic powders.

TAMARINDUS, *U. S., Br.*—Tamarind.

Pulpa tamarindorum cruda, P. G.; *Fructus tamarindorum (tamarindi).—Tamarind*, E.; *Tamarindenmus*, G.; *Tamarinier (pulpe)*, (Cod.), *Tamarin, Pulpe bruto de Tamarins*, Fr.; *Tamarindi in pasta, Pulpa di tamarindo*, It.; *Polpa de tamarindos em Rame*, Port.; *Tamarindo*, Sp.

The preserved pulp of the fruit of *Tamarindus Indica* L. (*T. officinalis* Hook.; *T. occidentalis* Gaertn.; *T. umbrosa* Salisb.—Fam. *Leguminosæ*).

Tamarind is official in nearly all pharmacopœias. The definition of the Br. P. is more definite than the above, specifying that the brittle outer part of the pericarp shall be removed and the remainder preserved in sugar. This is also more accurate, since the seeds as well as the pulp are included. The definition of the P. G. is much longer, but also provides for the inclusion of the seeds.

Origin and Properties.—The tamarind is a large, broadly spreading tree, much resembling the sugar-maple at a distance, native of India, and cultivated in nearly all tropical countries where there is sufficient rainfall, especially in the West Indies. The habit of the leaf, flower, and fruit is here illustrated. In the West Indies the fruit grows relatively much stouter than in the Orient, the length only about 3 times the breadth, this form being Gaertner's *T. occidentalis*. The indehiscent legume is of a rich brown color and smoothish. The exocarp is thin and brittle, the mesocarp fleshy, and bearing on its surface, on each side, three stout branching veins. The endocarp is thin, flexible, and tough, and divided transversely into from 3 to 10 cavities, each containing a flattened, somewhat quadrangular and glossy, dark-brown seed. The fresh leaves and flowers have an acidulous taste, and are used in tropical countries for the preparation of cooling drinks. Before tamarinds enter commerce the shell is removed, and the inner portion is in India pressed together into a mass to which sometimes sugar is added. In Upper Egypt it is formed into cakes which are dried in the sun, and in the West Indies hot syrup is poured over the pulpy mass. West Indian tamarinds are preferred in the United States, rather because of the method of their preparation than because of any natural difference in the fruit.

Fig. 439.

West Indian tamarind: flowering branch, pod, and pod with shell removed (fruit, ⅓ Nat.).

Description.—As seen in our commerce, tamarinds form a dark-brown soft mass, in which the interior portion of the fruit is more or less broken. They have a fruit-like odor and a subacid to strongly acid and sweet taste. *East Indian tamarinds* are tougher and darker in color and have a less sweet taste. *Egyptian tamarinds* appear in hard, flattish, circular cakes, about 15 Cm. (6 In.) in diameter, of a brown-black color externally, and frequently mouldy. The last two varieties are rarely met with in American commerce. On leaving the clean blade of an iron spatula for 30 minutes in contact with tamarinds, it should not become covered with a coating of copper.

The Austrian Pharmacopœia specifically excludes tamarinds of a reddish-brown color; the Russian allows about 17 per cent. of seeds; the Italian requires 12 to 13 per cent. of acid, chiefly tartaric.

Constituents.—C. Müller's analysis (1882) of East Indian tamarinds, which is generally accepted, gave a very little malic acid; citric acid varied between 6 and 4 per cent., tartaric acid between 5.3 and 8.8 per cent., potassium bitartrate between 4.7 and 6 per cent., the insoluble matter of the pulp between 12 and 20 per cent., and the seeds between 1.5 and 38 (average 13.9) per cent. A little acetic acid, which has been reported, is supposed to result from sugar-decomposition. There is a little tannin in the seed-coats.

Pharmaceutical Preparations.—Tamarinds are directed to be used in the preparation of confection of senna both by the U. S. and Brit. Pharmacopœias. A purified pulp of tamarinds is recognized in the Germ. Pharm. as *Pulpa Tamarindorum Depurata—Gereinigtes Tamarindenmus*. It is prepared by treating commercial tamarinds with hot water, straining the mixture through a coarse hair sieve, evaporating to the consistence of a thick extract, and incorporating 1 part of powdered sugar with every 5 parts of the extract. This purified pulp is of brownish-black color, and has a pleasant acidulous taste. If evaporated to dryness at 100° C. (212° F.) it yields 60 parts of residue. 2 Gm. of purified tamarind pulp, shaken with 50 Cc. of hot water and allowed to cool, should yield a filtrate, 25 Cc. of which should require not less than 1.2 Cc. of normal potassium hydroxide solution to become perfectly neutral.

Action and Uses.—The combination of acids and acid salts in tamarinds impart to them mild laxative and refrigerant properties. They are used in association with other laxatives, notably senna, in the treatment of habitual constipation, but are claimed

by some to detract from the efficacy of the other drugs. An infusion, strained and allowed to cool, is sometimes given as a grateful draught in fevers. The dose of tamarinds is from 1 drachm to 1 ounce (4–30 Gm.).

TANACETUM.—Tansy.

Summitates tanaceti.—Bitter-buttons, Hind-heel, Parsley or *Scented fern*, E.; *Rainfarn, Wurmkraut*, G.; *Tanaisie, Herbe aux vers*, Fr.; *Tanasia*, Port.; *Tanaceto*, Sp.

The dried leaves and tops of *Tanacetum vulgare* L. (*Chrysanthemum Tanacetum* Karsch; *Pyrethrum T.* DC.—Fam. *Compositæ*).

Tansy is official in a number of pharmacopœias, but has been dropped from the more important ones. A number recognize only the flower-heads (*Flores tanaceti*); several admit the entire plant.

Origin.—Tansy is a highly aromatic perennial herb, native of Europe and temperate Asia, widely naturalized in countries having a similar climate, and very abundant along roadsides, in waste fields, and similar localities in the eastern United States. The stout and fibrous many-headed root sends up a cluster of nearly simple stems, 3 or 4 feet high, roundish-angular, frequently purplish at the base, and bearing opposite leaves and a corymbose inflorescence.

FIG. 440.

Tansy plant (½ Nat.); leaf segment (× 2).

Description.—Leaves shortly and stoutly petioled, rarely exceeding 20 Cm. (8 In.) long and 10 Cm. (4 In.) broad, obovate when flattened, pinnate, the pinnæ about 10 or 12 pairs, linear-oblong, obtusish, pinnatifid, their segments oblong, acute, incisely serrate or lobed; thin, with a strong mid-rib, smooth, dark green, finely depressed-glandular; flower-heads in a small, loose, terminal corymb, long-peduncled, yellow, nearly 1 Cm. (about ⅓ In.) broad, having an imbricated, saucer-shaped involucre, a convex, naked receptacle, and numerous yellow tubular florets, which are perfect, or the outer circle pistillate; highly and peculiarly aromatic, the taste pungent and very bitter.

Constituents.—Together with resin, tannin, fat, sugar, gum, citric, tartaric, and malic acids, tansy contains about ½ per cent. of volatile oil (see OLEUM TANACETI) and the amaroid *tanacetin*, which was isolated by Leroy (1845) by a process similar to that for digitalin. This *tanacetin* is described as being yellowish-white, granular, inodorous, fusible, soluble in ether, less freely soluble in alcohol, and sparingly soluble in water. Leppig (1882) gives for it the formula $C_{11}H_{16}O_4$, and found it to be present chiefly in the flowers; sulphuric acid colors it yellow, then brown, red-brown, and blood-red, the margin becoming blue.

Action and Uses.—Tansy possesses carminative, emmenagogue, and anthelmintic properties, and in poisonous doses is a violent irritant to the stomach and intestines. Many deaths are recorded from its use. The symptoms preceding the fatal issue are variable, but consist usually in vomiting and purging, severe abdominal pain, a rapid, feeble pulse, dilated pupils, convulsions of an epileptiform type, coma, and asphyxia. The lethal doses of the drug or its volatile oil are undetermined. Very grave symptoms have followed the ingestion of from 15 to 30 minims (1–2 Cc.) of the oil of tansy. Tansy is another drug esteemed as a domestic remedy, and rarely employed in regular practice. It is used to promote or restore the menstrual function, and not infrequently as an abortifacient. Its employment for the latter purpose, however, not only fails to produce abortion, but is attended by grave dangers. In infusion it is given to remove lumbricoid worms from the intestine, as a febrifuge in mild fevers, and to correct hysterical disorders. The powdered drug is given in the dose of 20 to 60 grains (1.30–4 Gm.). The dose of the oil is from 1 to 3 minims (0.05–0.20 Cc.). In household medicine, tansy tea, made by adding 1 ounce (30 Gm.) of the leaves or tops to 1 pint (480 Cc.) of boiling water, is taken in the dose of 1 to 2 ounces (30–60 Cc.).

Other Species.—There are about 50 species in the genus *Tanacetum* L., distributed mostly throughout the North Temperate Zone, and several of them are used like the above. *T. umbelliferum* Boiss., of Persia and the adjacent region, is the *Busidan* or *Micha-akkar-kara*, used as an anthelmintic, purgative, and aphrodisiac. Its root is known as *White Pellitory*, and bears considerable resemblance to *Roman Pyrethrum*, though lighter colored, and of a sweetish and only slightly acrid taste.

TARAXACUM, *U. S.*—Taraxacum (Dandelion).

Taraxaci radix, Br.; *Radix taraxaci cum herba*, P. G.; *Radix taraxaci*, P. A.—*Dandelion root, Blow-ball, Milk, Witch*, or *Yellow gowan, Lion's-tooth*, etc., E.; *Löwenzahn, Pfaffenröhrchen*, G.; *Dent de lion, Pissenlit, Couronne de moine*, Fr.; *Radice do Tarassaco*, It.; *Diente de Leon*, Sp.

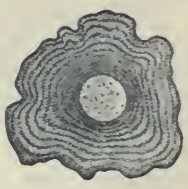
The dried root of *Taraxacum Taraxacum* (L.) Karsten (*Leontodon T.*—L.; *T. officinale* Weber; *T. Dens-leonis* Desf.; *T. vulgare* Schrank.—Fam. *Cichoriaceæ*), gathered in the autumn.

Taraxacum is official in nearly all pharmacopœias, most of which use the synonym *T. officinale* Weber, as is done by the U. S. P., the technical inaccuracy involved being less objectionable than the literary form of the correct name. The Swiss requires that it be collected in the spring. The German does the same, and includes the entire herb.

Origin.—The dandelion plant, native almost throughout the North Temperate Zone, and very widely dispersed, is so well known that a general description is superfluous. The young leaves are extensively consumed both as a pot-herb and as a salad. Although the species number more than a score, there is no reason to believe that the medicinal properties, which are rather insignificant, differ appreciably. The roots are chiefly collected in central Europe. Those collected in the United States are mostly small, branched, and inferior. The spring-collected root loses 80 to 85 per cent. on drying, that of the autumn only 70 to 75 per cent.

After frost and early in the spring, particularly when grown in a rich soil, the root contains much sugar and levulin; during the spring and summer the milk-juice becomes thicker and the bitter taste increases; the root is therefore directed to be collected in the autumn. The early spring root yields a sweetish-bitter extract. Bentley regards the root collected about July as most efficient. The Austrian Pharmacopœia directs also the leaves, *Folia taraxaci*, collected in the spring, for use in the preparation of the extract.

Fig. 441.



Transverse section of taraxacum root.

Description.—Mostly in pieces about 7 to 15 Cm. (3–6 In.) long and 1 to 2 Cm. ($\frac{2}{5}$–$\frac{4}{5}$ In.) thick, consisting of the upper portions of longer, tapering roots, usually simple or with one or two similar, parallel, and approximate, branches, crowned with several short, thickish crowns; dark brown, strongly longitudinally wrinkled when dry; fracture short, showing a thick, whitish bark marked with closely approximate circles of usually glistening latex-tubes and a thin, bright-yellow, porous wood; inodorous and bitter; free from starch.

Small roots of chicory might easily be mistaken for dandelion, but their transverse section reveals the lacticiferous ducts in radial rows.

Constituents.—A great amount of attention has been bestowed by Sayre upon the study of the constituents of taraxacum. He reports (1) a resin soluble in chloroform and ether, insoluble in alcohol; (2) a resin soluble in alcohol; (3) *taraxacerin* ($C_9H_{15}O$), a white waxy substance separating in cauliflower-like forms; (4) a bitter principle, which in somewhat concentrated solution is precipitated by a number of alkaloidal reagents. Solutions containing the seemingly pure principle when evaporated produced a film which under the microscope revealed oftentimes crystals of acicular form mixed with globules of oleoresinous appearance. When this mixture was treated with oxidizing agents—even by hydrogen peroxide—it was gradually converted into a crystalline mass which proved to be oxalic acid. The ash, of complex composition, amounted to nearly 12 per cent. In the autumn there is a large amount of inulin, which mostly disappears in early spring, when large amounts of sugar and levulin appear. The bitter principle has been called *taraxacin*. It was obtained by Sayre in a nearly pure condition to the extent of about 0.05 per cent.

Pharmaceutical Preparations.—Extract of Taraxacum, Fluidextract of Taraxacum, U. S. P.

Action and Uses.—Taraxacum was formerly largely employed for its mildly tonic, laxative, and diuretic properties. It was thought to greatly enhance the activity of the liver and promote the secretion of bile, but recent investigations disprove its hepatic influence. It is used, especially by German physicians, in the treatment of atonic dyspepsia and constipation associated with torpidity of the liver, and also in catarrhal jaundice and hepatic congestion. Its diuretic effect is too feeble to be of service. The best preparation of taraxacum is the fluidextract, given in the dose of 1 drachm to 1 ounce (4–30 Cc.). The dose of the extract is from 5 to 20 grains (0.30–1.30 Gm.).

Allied Drugs.—A large number of the milky-juiced *Compositæ*, or *Cichoriaceæ*, are very similar to dandelion in constituents and properties. Many have been used by aborigines and country people on fanciful grounds because the juice is milky; for example, *Lygodesmia juncea* is largely used by the North American Indians under names which mean *milk-medicine*.

Cichorium, *Chicory*, *Succory* or *Blue dandelion* (*Cichorie*, G.; *Chichorée*, Fr.), the dried root of *Cichorium Intybus* L., native of Europe and Asia, and growing commonly along roads and in waste places in the United States, is somewhat employed as a substitute for dandelion, besides being very extensively mixed with coffee. Its constituents are practically identical with those of dandelion. Its leaves are considerably used in salads, like those of the *Endive* or *Garden succory* (*C. Endivia* L.).

TEREBENUM, *U. S., Br.*—Terebene.

Terebène, Fr.; *Tereben*, G.

A liquid consisting of dipentene and other hydrocarbons, obtained by the action of concentrated sulphuric acid on oil of turpentine and subsequent rectification with steam.—U. S. The British Pharmacopœia states that terebene is obtained by the action of successive portions of sulphuric acid on oil of turpentine until it no longer rotates the ray of polarized light.

Preparation.—By repeatedly treating oil of turpentine with concentrated sulphuric acid or phosphoric anhydride it is rendered optically inactive. After purification this constitutes the so-called terebene. As a working formula Hirsch proposes the following method: Mix 1000 parts of oil of turpentine with 25 parts of sulphuric acid in one portion, and agitate thoroughly. When the heat generated has moderated to 70° C., add the same quantity of acid as before, and repeat this a number of times, taking care that the temperature does not rise too high. Shake the mixture at intervals for a short time, and put it aside for 24 hours. Remove the oil and wash it with solution of soda to remove all trace of acidity, and distil the oil in a brisk current of steam. The distillate thus obtained should be optically inactive, and if such is not the case the product should again be treated with sulphuric acid in the proportion of 5 to 100, the further procedure being as mentioned above. The inactive liquid finally obtained is a mixture of terebene with various hydrocarbons, from which terebene is obtained pure by fractional distillation, the portion boiling above 160° C. (320° F.) being rejected. According to Riban, it can be further purified by distilling over metallic sodium.

Properties and Tests.—Terebene is a colorless, thin liquid, having a rather agreeable thyme-like odor, and an aromatic, somewhat terebinthinate taste. Its specific gravity is about 0.850 at 25° C. (77° F.) (0.862 to 0.866 at 15.5° C. (60° F.), Br.). It is only slightly soluble in water, but soluble in 3 times its volume of alcohol. It boils at 155° to 165° C. (311° to 329° F.). On exposure to light and air, terebene gradually becomes resinified, and acquires an acid reaction, hence it should be kept in well-stoppered bottles, in a cool place, protected from light. Terebene should possess its characteristic agreeable odor, should not redden moistened blue litmus-paper (absence of acids), and should be completely inactive toward polarized light (absence of unaltered oil of turpentine). If about 10 Cc. of terebene is evaporated in a porcelain dish, on a water-bath, not more than a very slight residue should be left (absence of more than traces of resinous substances).—U. S. The British Pharmacopœia demands that not more than 15 per cent. should distil below 165° C. (329° F.). Tyrer and Westheimer (*Trans. Brit. Ph. Conf.*, 1900) state that commercial terebene will vary to some degree with the kind of oil of turpentine used and the conditions of its preparation, the products from Russian, French, and American oil of turpentine not being alike.

Action and Uses.—Terebene is stimulant to all mucous membranes, and in large doses is apt to severely irritate the stomach and kidneys. It is used chiefly in the later stages of acute bronchitis and in the chronic forms of the disease to liquefy and aid in

the expulsion of thick, tenacious mucus. For this purpose it is given by the mouth or inhaled in an oily spray. Terebene is also a mild antiseptic, and as such is employed in the treatment of fermentative dyspepsia. Its effect upon the genito-urinary tract is similar to that of other balsamic drugs, and it may be employed in chronic cystitis and urethritis, but is less efficacious than copaiba or sandal oil. Terebene is best given in capsule in the dose of 5 to 10 minims (0.30–0.60 Cc.). Another useful method is to drop the desired quantity upon sugar.

TEREBINTHINA, *U. S.*, *P. G.*—Turpentine.

Thus Americanum, Br.; *Terebinthina communis.*—*Crude turpentine*, E.; *Térébinthine commune*, Fr. Cod.; *Gemeiner Terpentin*, G.; *Balsamum pini*, Russ.; *B. Pinorum*, Nor.; *Terementine commune*, It.; *Trementina commune*, Sp.; *Leite* (or *Terebinthina*) *de Pinheiro*, Port.

A concrete oleoresin obtained from *Pinus palustris* (Miller) and from other species of *Pinus* (Fam. *Pinaceæ*).

Origin.—This definition would include the oleoresin of any true pine not excluded by the official description which, consisting as it does of but three lines of the most general description, seems designed to be thus comprehensive. The term, however, unless qualified, is generally construed as referring to the products of the long-leaved or pitch-pines of the southern United States, *P. palustris* Miller (*P. australis* Mx.) and *P. tæda* L. The former is often called the *Broom-pine*, the latter the *Old-field* or *Loblolly pine*. The forests of these trees originally covered most of the Atlantic coast plain from North Carolina to northern Florida, inclusive, and most of the Gulf plain from Florida westward. The methods of collection are very destructive and, in the absence of some energetic efforts at preservation, the industry seems doomed to an early practical extinction. The method of collection consists in chopping a pocket-shaped cavity called a "box," having a capacity of from a quart to a gallon, into the trunk a few inches above the ground, or several such boxes if the tree is very large. This work is done in the winter, and it is said that an expert can cut more than 10,000 boxes during the season. With the approach of warm weather the oleoresin begins to "run," and the boxes fill in about two weeks. To preserve the flow the bark and about ¼ inch of the wood are chipped off weekly above the edge of the box. The warmer and dryer the weather the more rapid the flow, but, on an average, the boxes fill once in 3 weeks. The product of the tree the first year it is cut is greater in amount and of better quality than that of any subsequent year, and is known as "virgin." The virgin yield of 10,000 trees is ordinarily regarded as about 200 barrels of 320 lbs. each, besides about 50 barrels of "scrape" or "scrapings," this being the product which dries and is scraped from the bark above and about the boxes. The trees continue to yield a profitable amount for about 3 or 4 years, after which they are abandoned to the lumbermen. By this time the bark will have been hacked to a height of from 5 to 8 feet above the boxes. More rational methods, by the use of vessels to catch the exudation, are being slowly introduced. In the early history of the industry nearly all of the turpentine was exported or shipped north for distillation, but the necessities of economy gradually caused the distillation to be performed at the point of collection. This was formerly done with iron, now with copper, stills. The yield of oil varies with the grade of turpentine. Virgin dip yields about 6 gallons to the barrel, common yellow dip of the second or third year about 4 gallons, and scrapings about 2 gallons.

Description.—Turpentine is a yellowish or brownish yellow, viscid liquid, which, when it exudes, is transparent, but soon becomes opaque from a crystalline deposit, is rendered thinner and clear by a moderate heat, and has an agreeable terebinthinate odor and a pungent, bitterish and acrid taste. In this condition turpentine is recognized by the pharmacopœias of Continental Europe, but in the United States and in Great Britain the oleoresin which has concreted on the trees is official, and is generally kept under the name of white turpentine, and in England is known as common frankincense. It is identical with the granular sediment deposited from liquid turpentine, and is found in irregular yellowish-white, more or less tough masses, which contain fragments of bark and wood, are brittle in the cold, breaking with a crummy fracture, and are more tenacious, or even semi-liquid, in warm weather. It contains from 12 to 16 per cent. of volatile oil, on the loss of which by exposure it becomes firm and friable.

The adulterations of turpentine are referable to the oil, and will be considered under that title.

Constituents.—The constituents of turpentine are described in connection with RESINA and OLEUM TEREBINTHINÆ, its two constituent parts.

Action and Uses.—The medicinal virtues of all the turpentines depend upon the volatile oil (see OLEUM TEREBINTHINÆ). Turpentine was anciently esteemed as a remedy in chronic inflammations of mucous membranes, as atonic amenorrhœa, catarrhal affections of the lungs and urinary organs, ulceration of the bowel, hemorrhoids, etc. In chronic rheumatic conditions it was administered internally, and its vapor at a high temperature applied in a bath. Its external application in ointment was resorted to for the cure of scabies and sluggish skin diseases. The dose of turpentine is from 20 to 60 grains (1.30–4 Gm.), given usually in pill or emulsion. Chian turpentine was recommended by Mr. Clay, of Birmingham, Eng., as a cure for uterine cancer. He gave it in the dose of 25 grains (1.60 Gm.) or more. Its present disuse reflects the opinion of the medical profession as to its value.

Other Turpentines.—The number of turpentines, many of them from species not in the genus *Pinus*, is too great to allow of their being named in this article. European turpentine closely resembles the American, and is obtained in Russia from *P. sylvestris* L. (the European Red, Scotch, Baltic, Norway, or Riga pine or "Scotch Fir"); in Germany from the same and from *P. rotundata* Link; in Austria, from *P. Laricio* Poir (the Corsican pine); in southwestern Europe, from *P. Pinaster Soland* (*P. maritima* Poir., the Cluster Pine or Pinaster). The last, or Bordeaux turpentine, is often called *Gallipot*. Aleppo turpentine is from *P. Halapensis* Miller (*P. maritima* Lambert). Mexican or Brea turpentine is from *P. Teocotl* Ch. and Sch., the Ocote pine. Hungarian turpentine (or balsam), Krummholzöl or Latschenöl, is from *P. Pumilio* Haenke, but, instead of being taken from the trunk, it is caused to exude by cutting off the tops of the branches in the spring.

Pinus Cembra L., the Siberian or Swiss stone-pine or Siberian cedar, yields a turpentine called Riga or Carpathian Balsam.

ABIETENE (C_7H_{16}) is the volatile oil obtained from the terebinthinate exudation of *Pinus Sabiniana*, Douglas, the Nut or Digger pine of California. According to Wenzell (1872), the crude oil is colorless, and commences to boil at 101° C. (213.8° F.), the thermometer gradually rising to 115° C. (239° F.). Pure abietene boils at 101° C. (213.8° F.), has a strong, penetrating orange-like odor, is highly inflammable, very volatile, of the specific gravity .694 at 16.5° C. (61.6° F.), soluble in 5 parts by measure of 95 per cent. alcohol, dissolves freely iodine and bromine, and yields with chlorine a substitution-compound boiling at 260° C. Thorpe (1879) found it to have the composition of *heptane* C_7H_{16}, to boil at 98.42° C., and to be slightly dextrogyre.

The volatile oil of *Pinus ponderosa* Douglas of California, which was examined by Sadtler (1879), seems to have the same composition.

A number of turpentines are obtained in India from various species of pines. (See *Agricult. Ledger*, 1896, No. 14.)

The European Larch, *Larix Larix* (L.), Karsten (*Pinus L.* L.; *Abies L.* Lam.; *Larix Europæa* DC.; *L. decidua* Mill.), yields the Venice or Larch turpentine, *Terebinthina laricine* (*T. laricis* or *T. veneta*; *Terebinthine de Venise*, Fr. Cod.; *Trementina de Venecia*, Sp.), which is obtained from the heart-wood by boring a hole into the trunk. It is a nearly transparent or slightly opaque and somewhat fluorescent thick liquid, of a terebinthinate odor, a bitter and aromatic taste, and a yellowish or greenish-yellow color. It is freely soluble in alcohol, amyl alcohol, acetone, and glacial acetic acid, and does not become hard when mixed with magnesia. The article usually sold here under this name is an artificial product. The average importation of Venice turpentine is about 48,000 pounds. Larch turpentine contains from 20 to 22 per cent. of volatile oil, having the odor of turpentine, a specific gravity of about 0.872, boiling at between 155° and 170° C. (338° F.) and soluble in alcohol. The remainder consists of about 14 to 15 per cent. of indifferent resin, and 60 to 64 per cent. of acid resins; *α-* and *β-larinolic acids* ($C_{18}H_{26}O_2$) are amorphous, *laricinolic acid* ($C_{20}H_{30}O_2$) is crystalline.

Chian turpentine (*Scio* or *Cyprian turpentine*, *Terebinthina chia* or *cypria*, *Alk gum*) is a totally different product, derived from *Pistacia terebinthus* L. (*P. Terebinthina* Lag.—Fam. *Anacardiaceæ*), a small tree of the Mediterranean region, and thence eastward. It exudes precisely like mastiche, to which it is closely related, and like it becomes hard and brittle with time. The genuine article is very scarce, and that of commerce is usually spurious, of Pinaceous origin. It is of a yellowish-green color, slightly like fennel in odor when fresh, soluble in alcohol, benzol and ether. It consists of about 10 or 12 per cent. of volatile oil, the remainder being resin.

TEREBINTHINA CANADENSIS, *U. S.*, *Br.*—Canada Turpentine.

Balsamum Canadense.—Canada balsam, balsam of fir, E.; *Térébenthine du Canada, Baume de Canada*, Fr. Cod.; *Canadischer Terpentin*, G.; *Trementina de Canada*, Sp.

A liquid oleoresin obtained from *Abies balsamea* (L.) Miller (Fam. *Pinaceæ.*, U. S. P.).

The Balsam, Balsam fir, Balm of Gilead fir, American silver fir, Fir pine, or Blister pine (Fig. 443), is a slender evergreen of 50 to 60 feet, abundant in the northern U. S. and Canada. Its dried leaves possess a deliciously sweet fragrance, and are esteemed for the making of "pine" or "balsam" pillows. The Indians of Hudson's Bay deprive the bark of its periderm, leaving the vesicles exposed, and dry it. This product, under the name *wayakosh*, is applied to wounds. It is bitter, astringent, and has the odor of this turpentine.

FIG. 442.

Abies balsamea (½ Nat.).

FIG. 443.

Instrument for collecting balsam of fir.

The oleoresin collects in bark-lacunæ, externally visible as transversely elongated blisters, which are pierced by the sharp nozzle of the collecting vessel here figured. The principal collecting districts are in Quebec. The average yield of a tree is about 8 ounces, less at each succeeding collection, these occurring at intervals of two or three years. A gallon is said to represent a good day's collecting for a man, with the assistance of two children.

The substance is yellowish or faintly greenish, transparent, viscid, of an agreeable terebinthinate odor, and a bitterish, slightly acrid taste. When exposed to the air, it gradually dries, forming a transparent mass. It is completely soluble in ether, chloroform, or benzol. Its principal value is derived from its perfect transparency and peculiar optical properties, which fit it for use in the mounting of miscroscopical specimens.

Its composition, so far as chemical analyses go, is practically the same as that of ordinary turpentine.

Tschirch and Bruening give the following composition: Volatile oil, mostly boiling between 160 and 167° C. (332.6° F.), 23 to 26 per cent.; indifferent resin ($C_{21}H_{40}O$), 11 to 12 per cent.; acid resins, about 63 per cent., these being *Canadinic* resin ($C_{19}H_{34}O_2$), *Canadolic acid* ($C_{19}H_{28}O_2$), and (the main part) α- and *β-Canadinolic acid* ($C_{19}H_{30}O_2$). The volatile oil is regarded as of very complex composition.

The so-called "Oregon Balsam Fir" is fictitious, being a preparation of ordinary turpentine.

Action and Uses.—The properties and uses of Canada turpentine differ in no essential from those of ordinary TURPENTINE (which see).

Other Fir Products.—The genus *Abies* Juss. contains about 20 species, of cool-temperate regions of the northern hemisphere, and some tropical mountains. There appears no reason why any one of them should not be utilized in medicine like that above considered.

Strassburg turpentine (*Terebinthina Argentoratensis; Térébentine d'Alsace* or *des Vosges, T. ou Citron*, Fr.) is actually so collected, on an extensive scale, from the vesicles of *A. Picea* (L.) Lyons (*Pinus Picea* L., *P. pectinata* Lam., *P. Abies* Du Roi., *Abies alba* Mill., *A. pectinata* DC., *A. excelsa* Link.), the European Silver Fir, Silver Pine, or Strassburg Pine. It closely resembles the Canada article, but has a lemon-like fragrance. Tschirch and Weigel give the composition of Strassburg turpentine as follows: Greenish, fluorescent volatile oil, of the specific gravity 0.860, boiling between 148 and 165° C. (329° F.), 28 to 30 per cent.; the amorphous resin *abiennic acid* ($C_{13}H_{20}O_3$), 8 to 10 per cent.; the crystalline resin *abietolic acid* ($C_{20}H_{28}O_2$), 1.5 to 2 per cent.; *α-* and *β-abietinolic acid* ($C_{16}H_{24}O_2$), 46 to 50 per cent.; a little succinic acid, bitter principle, and coloring-matter. From the young shoots of this species is distilled an "extra-fine pine-needle oil," highly prized in perfumery manufacture.

A somewhat similar oil is distilled from the young shoots of *A. Pichta* (Fisch.) Forb. (*A. Sibirica* Ledeb.), and one from the young cones of another species.

A. Menziesii Lindl., the Pacific Coast Balsam Fir, yields a product similar to Canada turpentine, rarely collected.

The term "Balm of Gilead Buds" is applied to the buds of *A. balsamea*, as well as (more properly) to those of *Populus candicans*.

The leaves of the Balsam Fir contain 5.13 per cent. of tannin, the stem-bark 12.49 per cent., and the root-bark 11.93 per cent. (*Bastin and Trimble*). Similar amounts of tannin have been found in other species.

(*Pix Burgundica*, also from this genus, is considered elsewhere).

Spruce Gum is to be regarded as a turpentine. It is derived from *Picea Mariana* (Mill.); B. S. P. (*P. nigra* Link; *Abies Mariana* Mill.; *Abies nigra* Desf.; *Pinus nigra* Ait.), a small tree of the northern part of North America. It collects in blister-like cavities of the bark, like Canada turpentine, and is either semi-soft when removed, or already hard. Sometimes it is found occupying longitudinal fissures in the wood. The latter is poorer, and is purified after collection. This article is used almost wholly as a masticatory, probably 500,000 pounds being consumed annually in this way.

TERPINI HYDRAS, *U. S.*—Terpin Hydrate.

Terpinum hydratum, P. G.; *Terpine*, Fr. Cod.—*Dihydrate de térébenthène, Hydrate de terpilène*, Fr.; *Terpinhydrat*, G.

Formula, $C_{10}H_{20}O_2 + H_2O$ or $C_{10}H_{18}(OH)_2 + H_2O$. Molecular weight, 188.74.

The hydrate of the diatomic alcohol terpin. Terpin hydrate should be kept in well-stoppered bottles.—U. S.

Preparation.—The French Codex alone gives a process for the manufacture of terpin hydrate, as follows: 39 Gm. of nitric acid of 1.39 specific gravity are mixed with 11 Gm. of water and the mixture allowed to cool. The liquid is then poured into a shallow dish, and 50 Gm. of 85 per cent. alcohol and 200 Gm. of French oil of turpentine added. After covering the dish loosely with paper it is set aside for several days at a temperature of 15° to 20° C. (59°–68° F.), the contents being stirred occasionally. As soon as crystals cease to be formed, they are removed and pressed between paper, the mother-liquor being neutralized with sodium hydroxide solution and made to yield a further crop of crystals. Finally the crystals are purified by solution in 95 per cent. alcohol and recrystallization.

The formation of terpin hydrate depends largely upon the temperature at which the reaction is allowed to go on. If the temperature be too high, resinification takes place, and if too low, terpin hydrate is formed very slowly. According to Krentmann (*Pharm. Zeitg.*, 1900), a larger yield of crystals is obtained if a solution of hydrogen dioxide is substituted for the alcohol. Terpin hydrate is also slowly formed if oil of turpentine be kept in contact with water for a long time.

Properties and Tests.—Terpin hydrate occurs in colorless, lustrous, rhombic prisms, nearly odorless, and having a slightly aromatic and somewhat bitter taste. It is permanent in the air. Soluble in about 200 parts of water, and in 10 parts of alcohol at 25° C. (77° F.); in 32 parts of boiling water, and in 2 parts of boiling alcohol; also soluble in about 100 parts of ether, 200 parts of chloroform, or 1 part of boiling glacial acetic acid. Terpin hydrate melts when quickly heated at 116° to 117° C. (240.8°–242.6° F.), with loss of water, and, at the temperature of boiling water, sublimes in fine needles. When heated in a flask adapted for distillation, it first loses water. At 258° C. (496.4° F.) anhydrous terpin distils over without decomposition, soon solidifying to a crystalline, hygroscopic mass, which melts at 102° to 105° C. (215.6°–221° F.). When strongly heated on platinum foil, it burns with a bright, smoky flame, leaving no residue. If to its hot, aqueous solution a few drops of sulphuric acid be added, the liquid will become turbid and develop a strongly aromatic odor. Terpin hydrate should not have the odor of turpentine, and its hot, aqueous solution should not redden blue litmus paper.—U. S. Terpin hydrate is insoluble in oil of turpentine, and is optically inactive.

Action and Uses.—Like the terebinthinates in general, terpin hydrate has a stimulant action upon mucous membranes. It was introduced into medicine as a remedy for chronic nephritis, but its employment in this disease is rare. It is quite extensively administered in subacute and chronic bronchitis and laryngitis to facilitate the expulsion of mucus from the inflamed part. Some cases of hay fever yield promptly to full doses of the drug. The average dose is 2 to 5 grains (0.12–0.30 Gm.), but it may be given in the dose of 15 to 20 grains (1–1.3 Gm.), 3 times a day in hay fever. It may be dispensed in capsule, suspended in mucilage, or dissolved in elixir, which should be strongly alcoholic to hold in solution enough of the drug so that the dose of the liquid be not too bulky.

Derivative Product.—Terpinol, Fr. Cod.—*Terpinol.*—If terpin hydrate be distilled in the presence of moderately dilute mineral acids, an oily liquid of pleasant odor is obtained, to which the name terpinol has been given (not to be confounded with terpineol). According to Wallach it consists of a mixture of terpineol, terpinene, terpinolene, and dipentene, in

varying proportions, depending chiefly upon the dilution of the acid employed. The French Codex directs that 100 Gm. of terpin hydrate be distilled with a mixture of 10 Gm. of sulphuric acid of 1.843 specific gravity and 500 Gm. of water, the resulting product being a colorless liquid, of 0.850 specific gravity, boiling between 170° to 220° C. (338°–428° F.), and having a pleasant hyacinth-like odor.

THEA.—Tea.

Thee, G.; *Thé*, Fr.; *Te, Te de China*, Sp.; *The dried leaves of Thea Chinensis* (or *Sinensis*) L. (*Camellia Thea* Link; *C. theifera* Griffith—Fam. *Theaceæ*).

Origin and Preparation.—Tea is obtained from a shrub which is indigenous to China and probably to other parts of southern and southeastern Asia, and has been cultivated in India, China, and Japan from a very early period. The varieties produced by long cultivation were formerly regarded as distinct species, and described as Thea Bohea, T. viridis, T. stricta, etc. The plant has been successfully introduced in several parts of the United States. It bears white axillary flowers and roundish-triangular, three-celled, and three-seeded capsules. The seeds are subglobular, somewhat flattened, of the size of a cherry stone, glossy brown, yellow at the hilum, and have a brittle testa, a short radicle, and unequal thick plano-convex cotyledons. There is probably no other agricultural product in the cultivation of which such refined methods enter as in that of tea. The finest Chinese tea is grown under shelter, neither sunshine nor rainwater being ever permitted to reach the growing leaves. Partly upon the methods of growing, but more largely upon those of preparing, depend the peculiarities of the very numerous varieties of commercial tea. After the leaves have been gathered, they are either rapidly dried, when they change to a dull-green color (green teas), or they are allowed to wilt, and are subsequently kept for some time in heaps, when they acquire a dark color (black tea). Both varieties are subjected to various manipulations, such as rolling upon a table, heating over a fire, etc., and are sometimes flavored by being left in contact with the flowers of the orange, fragrant olive, jessamin, and others. Hyson, Young Hyson, Gunpowder, and Imperial are some of the best-known brands of green tea, and Souchong, Oolong, and Pekoe are black teas.

Fig. 444.

Tea leaves (Nat.).

Very great improvements have recently been introduced into the manufacture of tea in India and Ceylon, chiefly through the efforts of Dr. (now Sir) George Watt. The careless, and even filthy, operations inseparable from the domestic and uncontrolled processes of manufacture which largely prevail in China have been replaced, in India, by methods of scientific accuracy and cleanliness.

Description.—Tea is met with in commerce in the form of little cylinders or rolls, into which the leaves have been twisted during the manipulation of rolling and in some varieties these leaves have again been formed into balls of different sizes. Tea leaves after having been softened in water and unfolded are found to be from 25 to 75 Mm. (1 to 3 In.) long, varying between oblong-ovate and oblanceolate in shape, short-stalked, pointed at both ends or blunt, sometimes emarginate at the apex and irregularly toothed at the margin. They have a prominent midrib, the lateral branches of which are curved upward near the margin. Tea has an agreeable odor, which varies, however, in the different varieties; its taste is pleasantly astringent and bitterish. The green color is not unfrequently heightened or imparted to tea by a mixture of Prussian blue and gypsum.

Constituents.—The important constituent of tea is from 1 to 4 per cent. of caffeine or "théine" (see Caffeina). About 15 per cent. (10 to 21 per cent. *Hooper*) of gallotannic

acid gives powerfully astringent properties to tea. Rochleder described *boheic acid* ($C_{14}H_{20}O_{12}$) as being amorphous, deliquescent, freely soluble in water and alcohol, and colored brown, but not precipitated, by ferric chloride, and precipitated by lead acetate. There are also small amounts of gallic acid, albumin, wax, resin, from ½ to 1 per cent. of volatile oil of a yellowish color, strongly aromatic odor and taste, and readily congealing. Two alkaloids isolated in very small amount are *theophylline*, an isomer of theobromine, highly diuretic, and *ademine* ($C_5H_5N_5$). The finest varieties of green tea contain the most tannin. The mode of drying (green or black) is said not to affect the percentage of caffeine, but the green will be the more astringent.

Synthetic Theophylline.—The very small yield of the natural alkaloid has until recently precluded its use in medicine, but in 1903 its synthetic production in large quantity, based on the researches of E. Fischer, Traube and others, made its use as a valuable diuretic possible. The name *theocine* has been given to the synthetic product for the purpose of distinguishing it from the natural alkaloid, and its manufacture on a commercial scale is now carried on in Europe under a German patent, involving the use of ammonia, carbon dioxide, potassium cyanide, acetic and formic acids in a series of 12 simple reactions. Theocine is the first instance of the successful production of an alkaloid on a commercial scale by strictly synthetic methods. It occurs in colorless needles, melting at 268° C. (514.4° F.), which are said to be insoluble in ether and difficultly soluble in alcohol. It requires 179 parts of cold water for solution, and considerably less than that of warm water. Like theobromine, theocine forms double compounds with the salts of ammonium, potassium, and sodium, of which the two first-named are said to be readily soluble and the latter only slightly soluble.

Action and Uses.—Taken in moderate quantity, tea quickens the activity of the brain and general nervous system, induces a grateful sense of exhilaration, a lively flow of ideas, and relieves hunger. Because of these pleasant effects, tea has become the favorite beverage of a great number of individuals, particularly those who lead sedentary, monotonous lives, and feel the need of something to arouse them from their lethargy. Another class who indulge freely in it are those who, though fatigued by mental or physical exertion, desire to continue their labor, even if it be at the expense of their reserve energy. It is affirmed by some and denied by others that tea diminishes tissue waste and the excretion of urea. The excessive use of tea results in derangement of the nervous system, manifested by vertigo, headache, ringing in the ears, tremors and mental confusion, and disorder of the digestion is common, as is evidenced by pyrosis, eructations, flatulence, and constipation. Dyspeptic symptoms are more apt to follow over-indulgence in green tea, which contains more tannin than the black variety. Owing to its tannin, tea may be used as a mild astringent in diarrhœa. A strong infusion of green tea may be used as an injection in subacute gonorrhœa and leucorrhœa, and as a gargle in sore throat. The wakefulness and stimulation induced by tea adapts it as a remedy in opium poisoning. It is one of the best remedies to relieve the headache due to nervous exhaustion. Theine, being identical with caffeine, may be employed interchangeably with it (see Caffeine).

Related Plants and Products.—Tea seeds contain about 20 per cent. of fixed oil, with saponin, the latter dissolving to some extent in the oil, thus rendering the latter undesirable for internal use. The seeds of the related plants *Camelia drupifera* Lour. and *C. Kissi* Wall. yield a fatty oil which is eaten and has many mechanical uses.

Other Caffeine-bearing Products.—The important sources of caffeine, Coffea, Guarana, Kola, and Theobroma, have been considered in order. The following American species of the genus *Ilex* are or have been consumed extensively for the same constituent: *Mate, Paraguay* or *Brazilian Tea* (*Jesuit's* or *St. Bartholomew's Tea,* E.; *St. Bartholomykraut, Jesuitenthée,* G.; *Maté,* Fr.; *Yerba Maté,* Sp.) is the dried leaves of *Ilex Paraguensis* St. Hil. (*I. Paraguariensis* Don.; *I. Paraguayensis* Hook.; *I. thœzans* Bonpl.—Fam. *Ilicineæ*), and of several other species of Ilex growing in Paraguay, southern Brazil, etc. The plants are large shrubs or small trees. The small, leafy twigs are gathered and dried, usually in ovens, and shipped to the towns, where they are garbled, prepared and packed for the market. They are marketed entire, or coarsely or finely powdered, according to the taste of the user. They constitute a very cheap substitute for tea, and most of those who have learned their use are said to prefer them to genuine tea. They are very generally consumed in southern Brazil and the adjacent regions. The leaves are oblong-lanceolate or oblong-ovate, about 5 Cm. (2 In.) long, obtusish, sparingly toothed, thick, and coriaceous, of slight odor and astringent and bitter taste. They contain usually from 0.5 to 1.5 per cent. of caffeine, about 15 per cent. of tannin, a little volatile oil, and a glucoside, besides ordinary plant-constituents.

Cassine (*Youpon, Dahoon, Black drink, Black draught, North American tea*) is the dried

leaves of *I. Cassine* L. This is in some respects one of the most interesting of North American medicinal plants. It is a small tree of the southeastern United States, growing chiefly near the coast. Its infusion was a favorite beverage of the North American Indians. Not only was it consumed by those who lived in its vicinity, but distant tribes made annual pilgrimages thither and engaged in trade, and celebrated religious rites, while remaining to drink of it. It thus becomes involved in important ways in the aboriginal history of our country. (See *Bulletin No. 14*, U. S. Dept. Agric., by Dr. E. M. Hale, of Chicago). It contains caffeine, to the extent of about ¼ per cent., with about 7 per cent. of tannin.

A great many vegetable substances which do not contain caffeine have been used as tea substitutes, and quite a number of them have been elsewhere referred to in this work. especially *Ledum* and *Ceanothus*.

THEOBROMA.—Cacao.

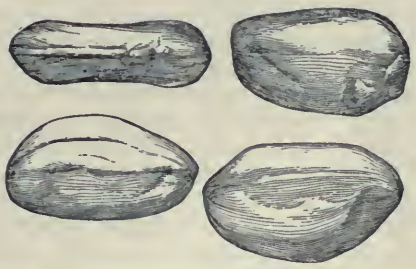
Semen, or *Fabæ cacao.—Cacao* (incorrectly "*Cocoa*") *beans* or *seeds*, *Chocolate beans* or *seeds*, E.; *Kakaobohnen*, G.; *Cacao, Fèves du Mexique*, Fr.; *Cacao*, Sp.

The prepared and dried ripe seeds of *Theobroma Cacao* L. (*Cacao sativa* Aubl.; *C. minor* Gaertn.; *C. Theobroma* Fuss.—Fam. *Sterculiaceæ*).

Cacao seeds are official in very few pharmacopœias, though their products, especially Oleum Theobromatis, are represented in all.

Origin.—The chocolate-tree is a native of tropical America, and is everywhere cultivated in tropical regions where the rainfall is abundant. It is of the size of a small apple tree, which it resembles in habit. The flowers are produced from the bark of the branches, or even of the trunk. The fruit is about 15 Cm. (6 In.) long, ovoid, longitudinally 10-grooved, terminates in a thick, nipple-shaped point, and resembles a small squash. It is of a yellow to orange-red color. The shell is somewhat like that of a squash, and it is filled with a soft, juicy, whitish, sweet pulp, in which numerous seeds, attached to a soft central placenta, are imbedded. After collection, the fruits are divided longitudinally and the contents scooped out. The seeds are then freed from pulp, the latter being often made into a delicious jelly. If the seeds are then dried, they will have a bitter and astringent taste. The practice is, therefore, to subject them to a sweating process to destroy, by fermentation, the tannin and bitter substance. Apparently, this sweating process results also in developing the derivative constituents on which the properties of chocolate depend, in part. This process is variously performed; sometimes by merely enclosing them in a tight box, and perhaps steaming, or placing in an oven. The original rude method of burying in pits in a clayey soil appears, however, to produce the best results, and the highest-priced cacao of the market is the yellow or orange-colored "clayed" Venezuelan article. "Claying" occupies about three days, after which the seeds are thrown into heaps and covered with leaves for about a week and dried.

Fig. 445.



Theobroma (Nat.).

Description.—The seeds are 15 to 25 Mm. (⅗–1 In.) long, ovate or oblong, somewhat flattened, and vary in color, according to the manner in which they have been prepared, from brown red to brown or grayish brown. A prominent raphe runs along one edge of the seed from one end to the other, uniting the hilum and chalaza, and is divided at the latter into many branching nerves. The testa is thin, papery, and fragile. The embryo has the shape of the seed, and consists of a small conical radicle and two large oily cotyledons, which are strongly ribbed upon their faces, and by the projecting folds of the inner seed-coat are divided from the back into numerous small irregular lobes, so that they readily break into many angular pieces. The odor of cacao-seeds is slight, but on warming is agreeably aromatic; their taste is oily, aromatic, and bitterish.

Among growers it is considered an indication of good quality when the cotyledons are shrunken away from one another, leaving a good-sized cavity between them.

Constituents.—From a pharmaceutical standpoint, the important constituent of cacao is its fat (see Oleum Theobromatis), which exists up to the extent of about 50 per cent. in the best seeds, and is contained in the kernel, which latter represents about 88 per cent. of the weight of the seed. Of more importance from a physiological stand-

point are the alkaloids, caffeine, 0.35 per cent. or less, and theobromine, of which the percentage is exceedingly variable. Of the latter, the entire seeds yield from less than 1 to about 2.5 per cent.; the seed-coats or "shells," an amount said to vary from less than 0.5 to 4.5 per cent. of their weight. The relations of those substances are of great interest and importance. Theobromine is said to be not present in the unfermented seeds, but to be developed in the curing process, through the conversion of a glucoside, the other products being dextrose and the coloring-matter *cacao-red*, of which there is about 5 or 6 per cent. Caffeine (*methyl-theobromine*) then results, and this can be artificially produced from theobromine by heating the silver compound with methyl iodide to 100° C. (212° F.). Other constituents of theobroma are about 15 per cent. of starch and an equal amount of proteids and 0.6 per cent. of sugar. The ash-yield of the seeds is about 3.5 per cent., of the kernel scarcely 3 per cent. There is also a very small amount of an unknown volatile and odorous principle. Caffeine is elsewhere discussed (see CAFFEINA). *Cacao-red*, soluble in water and alcohol and precipitated by lead acetate, appears to be combined with a proteid. When pure, it has a carmine-red color, and it is neutral to litmus. *Theobromine* or *dimethylxanthine* ($C_7H_8N_4O_2$), molecular weight, 179.75, occurs in minute white or colorless rhombic crystals, subliming without decomposition at 290° C. (554° F.), soluble in 736.5 parts of water at 18° C. (64.4° F.) in 818 parts of boiling absolute alcohol, in 21,000 parts of ether at 17° C. (62.6° F.), and in 15,808 parts of chloroform at 18° C. (64.4° F.), and is decomposed by warming with alkalies or earthy or hydrated lead oxide for some time (*Emminger*). It is neutral, but yields crystallizable salts which are decomposed by water. Emminger estimates theobromine by the following method, thus avoiding the necessity for dissolving it in ammonia and precipitating with silver nitrate, as previously recommended by Kuntze: Digest 10 grams finely powdered cacao in 150 parts petroleum spirit, dry the residue, and boil a weighed portion with 100 Cc. with a 3.4 per cent. solution of sulphuric acid in a flask with reflex condenser for about half an hour, until the formation of cacao-red ceases; neutralize the contents exactly, while hot, with a previously calculated quantity of baryta, evaporate to dryness with some sand, extract in a Soxhlet apparatus with 150 parts of chloroform for 5 hours, distil off the chloroform, and dry the residue at 100° C. (212° F.); wash the residue with not more than 100 Cc. of carbon tetrachloride, which dissolves the fat and caffeine; collect the insoluble theobromine on a filter, dissolve in boiling water, filter, evaporate, and weigh. It is said to be prepared most cheaply from the shells by boiling in water, filtering and pressing, precipitating tannin and coloring-matter with lead acetate, removing the lead with sulphuric acid, concentrating, adding burned magnesia, evaporating to dryness, extracting with 80 per cent. alcohol, and purifying by recrystallization from water.

Chocolate is made from Theobroma by roasting, removing the shells, breaking coarsely and removing the plumule, of stony hardness, grinding, the heat of friction being sufficient to melt the fat and produce a thick liquid, which is then run into molds and cooled. The fat may then be more or less completely removed by pressure between hot plates. The finest chocolate consists of the original, with the addition of some fat removed from the poorer grades. "Breakfast cocoa" consists of chocolate from which all the fat possible has been expressed. Chocolate is adulterated to a remarkable extent, a great variety of substances being employed, Thousands of tons of coco-nut-shells, raw or roasted, are thus used. Their presence is indicated by the presence of stone-cells, as is that of other nut-shells similarly employed. In Europe, ground chestnuts and other starchy substances are employed. Added starch to so slight an extent as 1 per cent. is said to be detected as follows: Boil 2 grains of the chocolate for 2 minutes in a test-tube with 20 Cc. of water, Cool, add 20 Cc. of water, and then, without shaking, 0.5 Cc. of a mixture of iodine 5, potassium iodide 10, and water 100. If pure, there may be a transient blue color, not lasting more than 12 minutes. If there is added starch, there will be an intense, persistent blue coloration (*Posetto*). For microscopical examination, a gram of finely powdered chocolate can be prepared by several extractions and decantations of ether to remove the fat, then one decantation with water, to remove the sugar. The starch grains of Theobroma are small (1 to 10 mikrons), single or compound, the former nearly circular in outline, with central films, and without lines, unless one or two close to the hilum.

Action and Uses.—The theobromine in cacao imparts to the nut stimulant properties closely resembling but less marked than those of tea or coffee. The fixed oil present

renders it highly nutritious. It contains only a trace of tannic acid, and is less likely to cause disorders of digestion than the other beverages. "Breakfast cocoa" particularly is easily borne by dyspeptics, because it is nearly free of fixed oil.

The genus *Theobroma* contains about a dozen species, and the seeds of several of them are used as Theobroma. *Caracas-cacao, Cacao blanco* or *Paporte* is the product of *T. bicolæ* H. et B. *Soconusco* or *Esmeraldas-cacao*, of Mexico, is derived from *T. ovalifolia* Sesse. The seeds of one or more species of *Herrania*, of South America, are similarly employed upon a very limited scale.

THUJA.—Thuja (Arbor Vitæ).

White, or Northern or False white cedar, Feather-leaf cedar, E.; *Thuya, Arbre de vie*, Fr.; *Lebensbaum*, G.

The fresh tops of *Thuja occidentalis* L. Fam. *Pinaceæ* (U. S. P., 1880).

Origin.—A handsome evergreen of northeastern North America, extending southward in the Alleghenies, reaching a height of about 50 feet, often planted, both at home and abroad, as an ornamental tree and for hedge-making. The branchlets spread out in a flattened or fan-like form, and the twigs are flattened, bearing 4 rows of closely imbricated and appressed scale-like leaves, which are 3 to 4 Mm. ($\frac{1}{8}$–$\frac{1}{6}$ In.) long, rhombic-ovate, obtusish or acutish. Those upon the sides are flat, those upon the edges folded into a boat-form. At the tips of the twigs the leaves are very broad, farther back they are elongated. A conspicuous elevated gland is borne upon the back, toward the apex, though many of these fall off in age. Thuja is strongly aromatic, pungent, camphoraceous, and bitter.

Fig. 446.

Thuja occid. branch (¾ Nat.); twig (×3).

Although sometimes dried, the drug is more active in the fresh state, and its common occurrence in cultivation renders it easily obtained. Care should be taken to distinguish it from the Asiatic *T. orientalis* L., which has the leaves grooved upon the back and wanting in the gland. Its branches are also erect, while those of the American are spreading.

Constituents.—Kawalier (1854–58) obtained from Thuja about 1 per cent. of volatile oil, a gelatinous compound, sugar, two resins, wax, a tannin identical with pinitannic acid, pinipicrin, and thujin. Pinipicrin and pinitannic acid are also found in the leaves and bark of *Pinus sylvestric* L., and doubtless occur elsewhere in the family. The volatile oil is colorless or greenish yellow, with bitter, sharp, camphoraceous taste, and a camphor-like odor resembling that of tansy. It has the specific gravity 0.925, boils between 190° and 206° C. (374° and 401° F.), and by fractional distillation can be separated into three portions (Wallach, 1892). It is readily soluble in alcohol, and with sulphuric acid or potassa turns black. *Pinipicrin* ($C_{22}H_{36}O_{11}$) is a yellow, bitter, powdery glucoside, which softens at 55° C. (130° F.), fuses to a transparent liquid at 100° C. (212° F.), and is not precipitated by lead salts. It dissolves in water, alcohol, and spirit of ether, but it is insoluble in pure ether. Boiled with dilute acids, it yields sugar and ericinol. *Thujin* ($C_{20}H_{22}O_{12}$) is a glucoside which forms astringent lemon-yellow crystals, and closely resembles quercitrin. It is soluble in hot water and alcohol, and with alkalies acquires a deep-yellow or red-brown color, and with ferric chloride turns green. It is precipitated by the acetate and subacetate of lead. Heated with dilute acids, it yields sugar and *thujigenin* ($C_{14}H_{12}O_7$), some of the latter being hydrolized to *thujetin* ($C_{14}H_{14}O_8$). These principles are almost insoluble in cold water, and, in alcoholic solution, acquire a handsome blue-green color with ammonia. Boiled with barium hydroxide, thujin is split into sugar and *thujetic acid* ($C_{28}H_{22}O_{13}$), which is insoluble in water.

Action and Uses.—Arbor vitæ somewhat resembles savin in its properties. Internally it may be used as an emmenagogue, and has been recommended in fevers, bronchial catarrh, rheumatism, and to remove intestinal worms. For these purposes it is administered in decoction or fluidextract. It has been applied locally in ointment to repress fungus granulations of ulcers, to remove warts and even cancerous growths. The ointment may be prepared either from the powdered leaves or from an oil distilled from them. The dose of the fluidextract is about 1 drachm (4 Cc.) given several times a day.

THYMOL, *U. S., Br., Fr. Cod.*—Thymol.

Thymolum, P. G.; *Acidum thymicum.—Thymic acid*, E.; *Acide thymique*, Fr.; *Thymiansaure, Thymolkampher*, G.

Formula, $C_{10}H_{14}O$ or $C_6H_3(CH_3)(OH)(C_3H_7)$. Molecular weight, 148.98.

A phenol occurring in the volatile oil of *Thymus vulgaris* L., and in some other volatile oils.—U. S.

A crystalline substance obtained from the volatile oils of *Thymus vulgaris* L., *Monarda punctata* L., and *Carum copticum* Benth. and Hook f., purified by recrystallization from alcohol.—Br.

Source.—Although thymol is found in several volatile oils, it is obtained for commerce chiefly from the oil of ajowan seed, the fruit of *Ptychotis Ajowan*. This oil is subjected to distillation, that portion passing over below 200° C. (392° F.) being collected. The residue, which has become rich in thymol by concentration, is then treated with sodium hydroxide solution, whereby the phenol is taken up as sodium-thymol, the resulting aqueous solution separated, diluted with water, and set aside until clear. Upon addition of hydrochloric acid the thymol is precipitated in the form of an oily layer, which is separated, and set aside in a cool place to solidify. If colored, the thymol may be treated with animal charcoal, and then crystallized from diluted alcohol.

The amount of thymol present in different oils varies considerably. Thus it is stated that while oil of thyme usually contains from 20 to 30 per cent. of thymol and its isomer carvacrol, ajowan oil contains from 45 to 55 per cent. of thymol, and oil of Monarda punctata as much as 60 per cent.

Properties and Tests.—Thymol occurs in large, colorless, translucent, rhombic prisms, having an aromatic, thyme-like odor, and a pungent aromatic taste, with a very slight caustic effect upon the lips. Its specific gravity as a solid is 1.030 at 25° C. (77° F.), but when liquefied by fusion it is lighter than water. It melts at 50° to 51° C. (122°–123.8° F.), remaining liquid at considerably lower temperatures. When triturated with about equal quantities of camphor, menthol, or hydrated chloral, it liquefies. Thymol is soluble in about 1100 parts of water at 25° C. (77° F.), and in less than its own weight of alcohol, ether, or chloroform; soluble in glacial acetic acid and fixed and volatile oils. Its alcoholic solution is optically inactive. If a very small crystal of thymol be dissolved in 1 Cc. of glacial acetic acid, and then 6 drops of sulphuric acid and 1 drop of nitric acid be added, the liquid will assume by reflected light a deep bluish-green color. If 1 Gm. of thymol be heated in a test-tube, in a water-bath, with 5 Cc. of a 10 per cent. solution of sodium hydroxide, a clear, colorless, or very slightly reddish solution should be formed, which becomes darker on standing, but without the separation of oily drops. If to this solution a few drops of chloroform be added and the mixture agitated, a violet color will be produced. An alcoholic solution of thymol should not be colored by ferric chloride test-solution. When a crystal of thymol is heated in an open dish, or in a watch-glass, on a water-bath, it should gradually volatilize, leaving no residue (absence of inorganic impurities).—U. S. Thymol should be kept in well-stoppered bottles in a cool place, on account of its volatile nature. If kept at ordinary room temperature, 25° C. (77° F.), it is apt to sublime on the sides of the container. Thymol acts as an antizymotic, but is inferior to carbolic and salicylic acids as an antiseptic.

Action and Uses.—Thymol was introduced into medicine as a substitute for phenol, the antiseptic and germicidal properties of which it possesses in almost equal degree. It has the advantage over phenol of a pleasant odor, of being much less irritating when applied locally, and of not causing toxic symptoms unless taken in very large amounts, at least 100 grains (6.6 Gm.) in 24 hours. In full medicinal doses its effects are similar to those produced by large quantities of salicylic acid—viz., a sensation of burning in the epigastrium, ringing in the ears, deafness, headache, and a marked decline in febrile temperature, accompanied by profuse sweating. The urine is sometimes decreased in quantity, and assumes a dark, greenish hue, due to the presence of oxidation products of thymol. In animals poisonous doses produce death by paralysis of respiration. The chief use of thymol is as an antiseptic. It is employed in mouth-washes for stomatitis, in gargles for tonsillitis, diphtheria, and other inflammations of the throat, in irrigations for otorrhœa, gonorrhœa, leucorrhœa, and ozena, and to correct the fetor of mucous discharges and sloughing wounds and ulcers. For these purposes solutions are employed

varying in strength from 1 to 10 parts dissolved in 1000 of water to which a small quantity of alcohol is added. In parasitic and sluggish skin diseases the application of an ointment containing 5 to 30 grains of thymol to the ounce (0.30–2.30 Gm.) is efficacious. It has the power of attracting flies, and in consequence its employment during the summer months is apt to cause annoyance to the patient. Internally thymol is recommended as an intestinal antiseptic in typhoid fever, diarrhœa, and dysentery, and as an antipyretic in many febrile affections. It is considered almost a specific in uncinariasis or hookwork disease. The dose of thymol is from ½ to 3 grains, given usually in capsule. It is best to follow it with a drink of milk to prevent it from irritating the stomach.

Derivatives of Thymol.—Thymacetin. $CH_3.C_3H_7.C_6H_2.OC_2H_5.NH.C_2H_5O$. — This compound bears the same relation to thymol as phenacetin does to phenol (carbolic acid), and is prepared in an analogous manner. It occurs as a white crystalline powder, sparingly soluble in water and ether, but readily soluble in alcohol.

Thymoform. $2(C_6H_3(CH_3)(C_3H_7)O).CH_2$.—A condensation product obtained by interaction upon heating 100 Gm. of thymol and 100 Cc. of a 40 per cent. solution of formaldehyde and gradually stirring in 100 Gm. of concentrated hydrochloric acid. The viscid oil, which separates after a violent reaction, is removed and thoroughly washed with water. It forms a yellowish, tasteless powder, having a faint odor of thymol. Thymoform is readily soluble in ether, alcohol, chloroform, and fixed oils, but is insoluble in water, glycerin, and petroleum benzin.

THYMOLIS IODIDUM, *U. S.*—Thymol Iodide.

Diiodothymol, Fr. Cod.; *Aristolum.—Dithymol diiodide, Aristol*, E.; *Dithymol biiodé*, Fr.; *Dithymoldijodid, Aristol, Annidalin, Thymotol*, G.

Formula, $C_{20}H_{24}O_2I_2$ or $(C_6H_2.CH_3.C_3H_7.OI)_2$. Molecular weight, 545.76.

Dithymol diiodide is obtained by the condensation of 2 molecules of thymol and the introduction of 2 atoms of iodine into the phenolic groups of the thymol; it contains 45 per cent. of iodine.—U. S.

Preparation.—The French Codex gives the following directions for the preparation of thymol iodide: Dissolve 60 Gm. of finely powdered iodine and 80 Gm. of potassium iodide in water, and dilute the solution to 300 Cc. Make a separate solution of 16 Gm. of sodium hydroxide and 15 Gm. of thymol, with sufficient water to make 300 Cc. of solution. Add the iodine solution to the alkaline solution of thymol, with constant stirring, and wash the resulting brown precipitate with 1 or 1½ liters of water, and dry the product at 40° to 50° C. (104°–122° F.).

Properties and Tests.—Thymol iodide is a bright, chocolate-colored, or reddish-yellow, bulky powder, with a very slight aromatic odor. It is insoluble in water and glycerin; slightly soluble in alcohol at 25° C. (77° F.); readily soluble in ether, chloroform, collodion, and in fixed and volatile oils, leaving a slight residue. It is decomposed when heated to a melting-point. It is not soluble in solution of sodium hydroxide, either cold or warm. When heated with concentrated sulphuric acid, it is decomposed with the separation of iodine. If 0.5 Gm. be shaken with 10 Cc. of water, the mixture, on filtering, will yield a filtrate which should not become more than opalescent on the addition of nitric acid and silver nitrate test-solution (absence of iodides). If 0.5 Gm. be shaken with 10 Cc. of water, and the mixture filtered, no blue color should be imparted by the filtrate to red litmus-paper (absence of alkalies). If 0.5 Gm. be shaken with 10 Cc. of water, and the mixture filtered, the filtrate should not be colored blue upon the addition of starch test-solution (absence of free iodine). If 0.1 Gm. of thymol iodide be thoroughly ignited in a porcelain crucible, it should leave not more than 0.003 Gm. of residue (limit of ash).—U. S. Thymol iodide is decomposed by light, and should be preserved in amber-colored vials, protected from the light.

Action and Uses.—Thymol iodide possesses in some degree the antiseptic properties of its component ingredients. It is used as a substitute for iodoform, chiefly because of its disagreeable odor. Its effect upon bacteria is not so powerful as that of iodoform, and it is not generally considered as efficient an antiseptic. It may, however, be employed with benefit in many cases. Internally it is claimed to be innocuous, but this can be true only when moderate doses are taken. Thymol iodide is an useful application in nasal, aural, and cutaneous affections, and in the treatment of wounds and sores when a mild antiseptic is indicated. It favorably influences the course of purulent otitis media, chronic rhinitis, balanitis, chancroids, ulcers, etc. It is applied either in powder or in

ointment (10 per cent.). Upon lupus it produces little effect, unless the surface is first curetted, and in psoriasis it is not so efficacious as chrysarobin. In fine powder it has been found of marked value in interstitial keratitis.

Allied Products.—Isobutylorthocresol Iodide. $C_{22}H_{29}O_2I$.—This compound, better known by its commercial name, *Europhen*, is prepared in a manner similar to that given above for thymol iodide, and is formed by reaction between a solution of iodine and an alkaline solution of isobutylorthocresol. It is a yellow powder, insoluble in water, but soluble in alcohol, ether, chloroform, and fixed oils. It contains about 28 per cent. of iodine. Europhen is permanent when dry, but when moistened with water, iodine is split off and a soluble iodine compound is formed. Europhen is used like thymol iodide.

Carvacrol Iodide. $C_{13}H_{13}OI$.—A yellowish-brown powder obtained if carvacrol be substituted for thymol in the process given above for the preparation of thymol iodide. It is insoluble in water, difficultly soluble in alcohol, but readily soluble in ether, chloroform, and olive oil. At 50° C. (122° F.) it begins to soften, and melts at 90° C. (194° F.) to a brownish-colored liquid.

THYMUS.—Thyme.

Herba Thymi, P. G.—*Common or Garden thyme*, E.; *Thymian, Gartenthymian, Römischer Quendel*, G.; *Thym*, Fr.; *Tomillo*, Sp.

The dried flowering herb of *Thymus vulgaris* L. (Fam. *Labiatæ*).

Origin and Description.—Thyme is a native of southern Europe, and is very largely cultivated, for medicinal purposes, for the extraction of the oil and thymol, and as a condiment. It is a low, slender, much-branched, hairy, highly aromatic perennial, the base more or less prostrate and rooting. The leaves are ovate-oblong or linear, revolute on the margin, grayish green, glandular-punctate on both sides and pubescent beneath, the upper ones bearing in their axils small clusters of whitish or reddish flowers with exserted stamens. The nutlets are about 1 Mm. ($\frac{1}{25}$ In.) in diameter, spheroidal, and finely tuberculate. The odor is agreeable, the taste warm, aromatic and pungent.

Fig. 447.

Thyme: flowering branch (slightly reduced); flower (× 3).

Constituents.—Besides a little tannin, resin, and unimportant substances, thyme contains about 2.5 per cent. of volatile oil (see Oleum Thymi), which constitutes its active constituent.

Action and Uses.—Thyme depends for its medicinal virtues upon its volatile oil (see Oleum Thymi). In infusion which is mildly diaphoretic and stimulant it is sometimes employed in domestic medicine.

Other Species.—The genus *Thymus* L. contains about 35 species, mostly of the Mediterranean region, and many of them have an odor similar to that of the above.

Fig. 448.

Serphyllum (¾ Nat.).

Serphyllum (*Herba Serphylli*, P. G.—*Wild thyme*, E.; *Feldthymian, Quendel*, G.; *Serpolet*, Fr.; *Serpol*, Sp.) is the dried flowering herb of *T. Serpyllum* L., a native of Europe and northern Asia, and sparingly naturalized in the United States. The stems are prostrate, more slender than those of the garden thyme, and usually purplish. The leaves are petiolate, flat, ovate, or roundish-lanceolate, occasionally linear, entire, ciliate near the base, glandular on both sides, otherwise smooth. The purple or rose-colored flowers are in aggregated heads or dense spikes terminating the branches, and have the four stamens included or sometimes exserted. It is a variable plant, including several nominal species, among them *Thymus citriodorus* Schreber, the *Lemon-thyme*, which has an agreeable odor resembling that of melissa and of lemon. In odor, taste, constituents, properties and uses, it agrees closely with garden thyme.

TILIA.—Linden-flowers.

Flores tiliæ, P. G.—*Lime-flowers, Basswood (Bast-wood) Flowers, Locust-bloom, Tiltree Flowers*, E.; *Lindenblüten*, G.; *Fleurs de tilleul*, Fr.; *Tilo*, Sp.

The dried inflorescence of *Tilia Europæa* L. and of other species of *Tilia* (Fam. *Tiliaceæ*).

Origin.—The *Linden, Lime, Basswood*, or *White-wood* trees are about 16 in number, natives of the North Temperate Zone, of about the dimensions of the elm, and largely planted for ornament and shade. The wood is soft but very tough, and is used in a great variety of important ways. The bark is very fibrous and tough, the leaves alternate, stipulate, petioled, broadly and usually obliquely heart-shaped, and serrate. The flower-clusters are abundant, axillary, and drooping, and very fragrant, being much sought by honey-bees.

FIG. 449.

a *b*

Tilia Europæa: *a*, flower (× 2); *b*, stamen-cluster (× 3½).

Description.—Cymes 3- to many-flowered, the peduncle united by its lower portion to the midrib of a large oblong or lance-oblong greenish-yellow bract; flowers yellowish or greenish white, pedicelled, 5-merous, the parts free and distinct, except that the original (mostly 5) stamens have each developed a cluster of stamens and, in the European species, an extra, narrow petal; ovary 5-celled, style stout, stigma 5-lobed; fruit a globular, nut-like, 1-celled capsule, containing 1 or 2 seeds.

Constituents.—Tilia flowers contain nearly 0.05 per cent. of a colorless, very thin volatile oil, of delightful fragrance, soluble in alcohol and ether in all proportions. There are also gum, sugar, pectin, fat, little tannin, etc. The glucoside *tiliacin*, occurring in the leaves, may be expected also in the inflorescence-bract, which is herbaceous, and which forms a part of the drug. This glucoside yields *tiliaretin* and this yields anisic acid.

Action and Uses.—An infusion of linden flowers is used in household medicine, especially on the Continent, to relieve nervous headache, hysteria, and painful indigestion, and to abort colds. The infusion is made by adding 30 to 60 grains (2–4 Gm.) of the flowers to 1 pint (480 Cc.) of water.

TILIACEÆ (The Linden Family).

This is a small family of 35 genera and about 300 species of trees and shrubs. Chief interest in the family relates to its tough bast-fibers, some of which are used for cordage. *Jute* is the product of several species of *Corchorus*. *Maqui* is the fruit of *Aristotelia Macqui* L'Herit. (*Cornu Chilensis* Mol.) of Chili, much used for imparting a fine red color to wine. The fruits of some species of *Grewia* are used as fish-poisons. *Tang-li* is a Chinese remedy for diarrhœa, consisting of the leaves and fruits of *G. Asiatica* L. The East Indian species, *G. tiliæfolia* Vahl. (*Dhamani* or *Tharra*) is reputed as an antidote to opium-poisoning. The root of *G. scabrophylla* Roxb. (*Katkhati*) is a substitute for Althæa. *Muntingia Calabura* L. and *Prockia dulcis* L. yield edible fruits. The bark of *Lühea grandiflora* Mart. is used in Brazil as an astringent, under the name *Azoite Cavallo*. Various species of *Triumfetta* are used in the West Indies as astringents, especially in gonorrhœa, under the names *Cousin Mahaut* and *Cardillo de Perro*. The seeds of the South American tree *Apeiba Tibourba* Aubl. (*Cabeza de Negro* or *Nigger-head*) yield a peculiar fixed oil of disagreeable odor.

TINCTURÆ.—Tinctures.

Teintures, Alcoolés, Fr.; *Tinkturen*, G.; *Tinturas, Alcoholados*, Sp.

Tinctures are solutions of non-volatile or only partially volatile substances, in liquids other than simple water or glycerin, and which invariably contain alcohol; solutions of volatile substances in alcohol are always termed spirits or essences. While tinctures are usually assumed to be solutions of vegetable principles, this is not the case in all the official tinctures; two of these, the tinctures of iodine and ferric chloride, are solutions of inorganic substances, and must also be classed as exceptions to the rule that tinctures are solutions of non-volatile substances. The menstruum or solvent used in the preparation of tinctures may be simply alcohol, various mixtures of alcohol and water, or of

alcohol, glycerin, and water, ammoniated alcohol in the form of aromatic spirit of ammonia, and mixtures of alcohol and ether; according as these different menstrua are employed, tinctures are divided into groups designated as alcoholic, hydro-alcoholic, ammoniated, and ethereal tinctures, respectively.

The U. S. Pharmacopœia recognizes 64 tinctures, of which 18 are made with alcohol, 44 with a hydro-alcoholic menstruum, and 2 with ammoniated alcohol; from this it is seen that the tendency is in the direction of weaker alcohol, and many tinctures formerly made with alcohol exclusively are now found equally efficient and permanent when made with a mixture of alcohol and water. The valuable solvent and preservative properties of alcohol are retained in the various hydro-alcoholic mixtures, in which the proportions of alcohol and water are so adjusted that complete extraction of the valuable constituents of the drug is insured as well as permanence of the solution; the solution of much inert and unstable matter is likewise thus avoided. Tinctures made with weak alcohol are also more readily miscible with aqueous liquids—a point often of great value in dispensing medicines. The addition of glycerin to the menstruum is frequently desirable to facilitate the perfect extraction of astringent and other principles, and to prevent subsequent changes in the finished tincture, due to atmospheric influences, which cause gelatinization of the solution or deposit of unsightly precipitates.

Preparation.—Tinctures of resins, oleoresins, balsams, and most gum-resins and extractive drugs are best prepared by maceration. Specific directions are given under each official process, and maceration should be conducted preferably at a temperature of about 15° to 20° C. (59°–68° F.), and in a shady place. Nearly all other drugs are conveniently extracted by percolation, which process is fully described in the Pharmacopœia, as given below, and if the process is properly conducted the drug will be practically exhausted long before the requisite amount of tincture has been obtained.

Official Process of Percolation.—"The percolator is prepared for percolation by pressing a small tuft of cotton into the neck above the cork, and this may then be moistened by pouring a few drops of the menstruum upon the cotton, to facilitate the passage of the first portion of the percolate, which is often very dense.

"The powdered substance to be percolated (which must be uniformly of the fineness directed in the formula, and should be perfectly air-dry before it is weighed) is put into a basin, the specified quantity of menstruum is poured on, and the powder thoroughly stirred with a spatula, or other suitable instrument, until it appears uniformly moistened. The moist powder is then passed through a coarse sieve—No. 40 powders, and those which are finer, requiring a No. 20 sieve, while No. 30 powders require a No. 15 sieve for this purpose. Powders of a less degree of fineness usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper, and the whole quantity poured from this into the percolator. It is then shaken down lightly and allowed to remain in that condition for a period varying from fifteen minutes to several hours, unless otherwise directed; after which the powder is pressed, by the aid of a plunger of suitable dimensions, more or less firmly, in proportion to the character of the powdered substance and the alcoholic strength of the menstruum, strongly alcoholic menstrua, as a rule, permitting firmer packing of the powder than the weaker. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately fitting disk of filtering paper or other suitable material, and a sufficient quantity of the menstruum poured on through a funnel reaching nearly to the surface of the paper. If these conditions be accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached, in this, a height corresponding to its level in the percolator, which is now closely covered to prevent evaporation. The apparatus is then allowed to stand at rest for the time specified in the formula.

"To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle previously marked for the quantity of liquid to be percolated, if the percolate is to be measured, or of a tared bottle, if the percolate is to be weighed; and by raising or lowering this receiver the rapidity of percolation may be increased or decreased as may be desirable. A layer of menstruum must constantly be maintained above the powder so as to prevent the access of air to its interstices, until all has been added, or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire

quantity of menstruum over the percolator in such a manner that its mouth may dip beneath the surface of the liquid, the bottle being of such shape that its shoulder will serve as a cover for the percolator.

"When the dregs of a tincture, or of a similar preparation, are to be subjected to percolation, after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as before described, and the liquid poured on, until all has passed from the surface, when immediately a sufficient quantity of the original menstruum should be poured on to displace the absorbed liquid, until the prescribed quantity has been obtained.

"It is obvious that the success of the process of percolation largely depends upon the regulation of the flow of the percolate; if this should be too rapid, incomplete exhaustion will result, but if too slow, valuable time may be wasted. The rate of flow for extracts and fluidextracts for 1000 Gm. of powder should range from 2 to 5 drops a minute; for official quantities of tinctures and preparations of about the same strength from 8 to 15 drops a minute, and the word "slowly" throughout the text is understood to mean a rate of flow corresponding to this; it is evident that the proper rate of flow should vary with the quantity and character of the drug employed and the density of the menstruum."

In connection with the official formulas for tinctures, specific directions are given as to the length of time the moistened drug is to stand before being packed, and also how long the packed drug is to be macerated after saturation with menstruum, before percolation is allowed to go on. This previous treatment of the drug is for the purpose of insuring perfect exhaustion, and has been found very effectual, but there are a few exceptions, where maceration before percolation has been found unnecessary or undesirable.

The British Pharmacopœia employs both percolation and maceration in the preparation of tinctures. In the former case the solid materials are moistened with the prescribed quantity of menstruum, and set aside in a closed vessel for 24 hours. The mixture is then packed in a percolator, firmly or lightly according to the nature of the drug, and further portions of the menstruum poured over the contents at intervals, until a sufficient quantity of menstruum has been used to produce about ¾ of the volume of the finished tincture. When liquid ceases to pass, the marc is removed from the percolator and expressed. The expressed liquid is filtered, either at once or after 24 hours, and mixed with the percolate, sufficient menstruum being finally added to produce the prescribed volume of tincture. If the tincture is to be made by maceration, the solid materials, together with the whole quantity of the menstruum, are placed in a closed vessel and allowed to stand for 7 days, with frequent agitation. The mixture is then strained and the marc expressed. After mixing the two liquids the whole is filtered.

The German Pharmacopœia prepares all tinctures by maceration. The drugs, either coarsely powdered or cut into thin slices, and the menstruum are introduced into a bottle, which should be only partly filled, so as to permit the frequent agitation of the contents; after macerating in a shady place at about 15° C. (59° F.) for a week, the liquid is decanted and the residue subjected to pressure; the liquids thus obtained are mixed, set aside for a day or two, and then filtered, care being taken to prevent the evaporation of alcohol. The liquid which remains absorbed in the drug is not replaced.

The French Codex directs its tinctures to be made by maceration or by displacement. For the latter process the directions are similar to those of the United States Pharmacopœia, except that the powder is ordered to be of medium fineness and is not moistened previous to its introduction into the percolator.

Strength of Tinctures.—The strength of the tinctures of the U. S. Pharmacopœia varies from 1.6 Gm. to 50 Gm. of drug, being in the majority of cases 10 or 20 Gm., for every 100 Cc. of finished product. 11 of the official tinctures are directed to be standardized to a definite alkaloidal strength, thus: Aconite, belladonna leaves, cinchona, colchicum seed, hydrastis, hyoscyamus, nux vomica, opium, deodorized opium, physostigma, stramonium. In accordance with suggestions made by the International Conference for Unification of Formulas for Potent Remedies, held at Brussels, in Belgium, in September, 1902, and in a few cases also for other reasons, a number of tinctures have been reduced in strength and others have been increased, as compared with the 1890 Pharmacopœia, as shown below:

Increased in Strength.—Tinctures of calumba, cantharides, capsicum, cinnamon, orange (sweet), quassia, rhubarb, serpentaria, strophanthus, and tolu.

Reduced in Strength.—Tinctures of aconite, belladonna leaves, benzoin (compound), catechu, cannabis (Indian), colchicum seed, deodorized opium, digitalis, gelsemium, hyoscyamus, kino, lobelia, opium, physostigma, sanguinaria, squill, stramonium, and veratrum.

The British Pharmacopœia of 1898 offers duplicate formulas for the preparation of its tinctures: in one, imperial weights and measures are employed, in the other, metric weights and measures. The strength of the official British tinctures varies from ¼ ounce to 5 ounces of drug in 1 imperial pint (20 fluidounces) of finished product, or from 12.5 Gm. to 250 Gm. in 1000 Cc.; of the 68 tinctures recognized, 29 are directed to be made by percolation and 26 by maceration. The French and German Pharmacopœias direct their tinctures to be prepared by maceration, and, almost without exception, of such strength that 1 part of drug is represented by about 5 or 10 parts of tincture by weight.

Preservation.—Upon exposure to air and light, tinctures, like all vegetable solutions, are prone to undergo change, and should, therefore, be kept in well-closed containers, in places not exposed to direct sunlight; extremes of temperature are equally hurtful on account of possible change in the menstruum. Fortunately, the deposits formed in tinctures consist, as a rule, only of inert extractive matter, which may be removed by filtration.

TINCTURA ACONITI, *U. S., Br., P. G.*—Tincture of Aconite.

Tinctura aconiti radicis.—Tincture of aconite-root, E.; *Teinture de racine d'aconit*, Fr.; *Akonittinktur, Eisenhuttinktur*, G.

Note.—The strength of this tincture has been reduced from 35 Gm. (1890) to 10 Gm. of aconite in 100 Cc.—U. S.

Preparation.—Aconite, in No. 60 powder, containing not less than 0.5 per cent. of aconitine, 100 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix alcohol and water in the proportion of 700 Cc. of alcohol to 300 Cc. of water. Moisten the aconite with 40 Cc. of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it very firmly, and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, gradually adding menstruum until 1000 Cc. are obtained.

Tincture of aconite, when assayed by the process given below, should contain in 100 Cc. 0.045 Gm. of aconitine.—U. S.

To make 1 pint of tincture of aconite, use 730 grains of the powdered aconite root, and moisten with 5 fluidrachms of the menstruum (alcohol 7 volumes, water 3 volumes). After maceration, percolate until 16 fluidounces of tincture have been obtained.

Aconite-root, in No. 40 powder, 1 ounce; alcohol (70 per cent.), sufficient to make 1 imperial pint (20 fluidounces) of tincture, by percolation.—Br.

Aconite-root, in coarse powder, 1 part; alcohol (68.5 per cent.), 10 parts. Make the tincture by maceration.—P. G.

Aconite-root, in coarse powder, 20 Gm.; alcohol (60 per cent.), 1000 Gm. Macerate for 10 days, express, and filter.—Fr. Cod.

Assay of Tincture of Aconite.—Transfer 100 Cc. of tincture of aconite to an evaporating dish and evaporate it carefully to dryness at a temperature not exceeding 60° C. (140° F.), and assay the resulting extract by the method given under Fluidextractum Aconiti (page 649), using the same details as there directed for 10 Cc. of fluidextract of aconite, with the exception that the multiplication of the product by 10 must be omitted; the result will represent the weight in grammes of aconitine contained in 100 Cc. of tincture of aconite.—U. S.

It will be found advantageous to add about 5 Gm. of powdered pumice stone to the tincture while evaporating, since the resulting residue will then be more readily acted upon by the acid liquid and the mixture be more easily filtered. Should the tincture be found to contain more aconitine than officially prescribed, it should be diluted with the proper amount of menstruum, and, on the other hand, if found deficient in aconitine, it should be concentrated, by evaporation at a gentle heat, until the official standard is obtained.

The present official tincture of aconite is considerably weaker than that of 1890, which latter represented about 160 grains of aconite in each fluidounce, but was not standardized to a definite alkaloidal content. It contains in each Cc. 0.00045 Gm., or in each fluidrachm about $\frac{1}{3\,6}$ grain, of aconitine. This fact must not be overlooked in determining the dose to be administered.

Tincture of aconite leaves is still recognized in the French Codex, and is made according to that authority, of the same strength as its tincture of aconite root.

The selection of efficient root and its careful percolation are of the utmost importance. The tincture is of a yellowish-brown color, and on the addition of water becomes milky from the precipitation of resin.

FLEMING'S TINCTURE OF ACONITE is still prescribed by some physicians; it is prepared by carefully percolating 10 troyounces of powdered aconite root with sufficient alcohol to obtain 15 fluidounces of tincture. Since the introduction of the very efficient official fluidextract of aconite there seems no longer to be any necessity for this tincture.

Uses.—The tincture is the preparation of aconite most frequently employed. Because of the decrease of the strength of this tincture in the U. S. P., 1900, the dose must be larger, and is from 3 to 10 minims (0.20–1 Cc.).

TINCTURA ALOES, *U. S., Br., P. G.*—Tincture of Aloes.

Teinture d'aloès, Fr.; *Aloetinktur*, G.; *Tintura de Acibar*, Sp.

Preparation.—Purified aloes, in No. 40 powder, 100 Gm.; glycyrrhiza, in No. 40 powder, 200 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Macerate the purified aloes and glycyrrhiza in a stoppered container, in a moderately warm place with 750 Cc. of diluted alcohol, for 7 days, with occasional agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pass enough diluted alcohol through the residue to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of aloes macerate 730 grains of purified aloes and 3 avoirdupois ounces and 148 grains of licorice root, both in No. 40 powder, with 12 fluidounces of diluted alcohol for 7 days, and after filtration pass sufficient diluted alcohol through the residue to bring the volume up to 16 fluidounces.

Take of extract of Barbadoes aloes ½ ounce; liquid extract of licorice, 3 fluidounces; alcohol (45 per cent.), a sufficient quantity. Place the extract of Barbadoes aloes in a closed vessel with 16 fluidounces of the alcohol; set aside for 48 hours, occasionally shaking until dissolved; add the liquid extract of licorice; filter; pass sufficient of the alcohol through the filter to produce 1 imperial pint (20 fluidounces) of the tincture.—Br.

The formulas of other pharmacopœias require: Aloes, 1 part; alcohol (90 per cent.), 5 parts.—P. G. Aloes, 1 part; alcohol (60 per cent.), 5 parts.—Fr. Cod.

Tincture of aloes has a dark, blackish-brown color and a bitter taste, which latter, however, is considerably modified by the licorice.

Uses.—On account of the large dose required (½ ounce [16 Cc.]), this preparation is rarely used as a purgative, but may be given as a laxative in the dose of 2 drachms (8 Cc.). It has been applied locally to indolent ulcers, excoriations, bed-sores, and fissures.

TINCTURA ALOES ET MYRRHÆ, *U. S.*—Tincture of Aloes and Myrrh.

Elixir proprietatis Paracelsi.—Elixir de propriété, Fr.; *Aloëelixir*, G.

Preparation.—Purified aloes, in No. 40 powder, 100 Gm.; myrrh, in No. 40 powder, 100 Gm.; glycyrrhiza, in No. 40 powder, 100 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water. Macerate the purified aloes, myrrh, and glycyrrhiza in a stoppered container, in a moderately warm place, with 750 Cc. of the menstruum, for 7 days, with occasional agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pass enough menstruum through the residue to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of aloes and myrrh macerate 730 grains each of purified aloes, myrrh, and licorice root, all in No. 40 powder, with 12 fluidounces of menstruum

(alcohol, 3 volumes; water, 1 volume), for 7 days, and after filtration pass sufficient menstruum through the residue to bring the volume up to 16 fluidounces.

The color of this tincture is deep reddish brown; if prepared with saffron, it is of a rich orange brown. It is precipitated by water.

In this connection should be mentioned the following preparation, which has long enjoyed considerable reputation on the continent of Europe:

Tinctura Aloes Composita, P. G.; *Elixir ad longam vitam, Elixir suedicum.—Compound tincture of aloes, Swedish bitters,* E.; *Elixir de longue vie, Elixir suédois,* Fr.; *Lebenselixir,* G.—Aloes, 6 parts, and gentian, rhubarb, zedoary, and saffron, each 1 part, are macerated for a week with 200 parts of alcohol, specific gravity 0.894; the tincture is expressed and filtered.—P. G. The formula of the French Codex reduces the aloes to 4 parts, the other ingredients to ½ part, and adds ½ part each of agaric and of confection of opium.

Uses.—The combination of myrrh and aloes renders this preparation of service as an emmenagogue to be given in amenorrhœa associated with constipation. The dose is 1 to 2 drachms (4–8 Cc.).

TINCTURA AMARA, *P. G.*—Bitter Tincture.

Teinture amère, Fr.; *Bittere Tinktur,* G.

Preparation.—Gentian, 3 parts; European centaury, 3 parts; bitter orange-peel, 2 parts; orange berries, 1 part; zedoary root, 1 part; alcohol (68½ per cent.), 50 parts. Reduce the drugs to a moderately fine powder, add the menstruum, and macerate for 7 days with occasional agitation. Then filter.—P. G.

Bitter tincture is of greenish-brown color, and has an aromatic odor and spicy bitter taste.

Uses.—Bitter tincture is a grateful stomachic and a stimulant to the appetite and digestion. It is given in the dose of 1 to 2 drachms (4–8 Cc.).

TINCTURA ARNICÆ, *U. S., Br., P. G.*—Tincture of Arnica.

Teinture de fleur d'arnica, Fr.; *Arnikatinktur,* G.

Preparation.—Arnica, in No. 20 powder, 200 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Macerate the arnica with 500 Cc. of diluted alcohol in a closed vessel, in a moderately warm place, for 3 days, with occasional stirring, and express strongly. Repeat this operation twice successively with 250 Cc. of diluted alcohol, macerating for 24 hours each time; then, having ascertained the volume of the united expressed liquids, macerate the residual marc for 6 hours with sufficient menstruum to make approximately 1000 Cc. and express as before. Mix the expressed liquids, filter through paper, and pass sufficient diluted alcohol through the filter to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of arnica macerate 3 avoirdupois ounces and 148 grains of ground arnica flowers with 8 fluidounces of diluted alcohol for 3 days and express strongly. Macerate twice more, each time with 4 ounces of diluted alcohol for 24 hours and again express. Measure the volume of expressed liquids and macerate the residue for 6 hours with sufficient menstruum to make 16 fluidounces. Finally filter.

The British Pharmacopœia directs 1 ounce of arnica rhizome, in No. 40 powder, to be percolated with 70 per cent. alcohol to obtain 1 imperial pint (20 fluidounces) of tincture. This tincture being made from arnica root differs materially in color, odor, and taste from the U. S. P. tincture, and is almost identical with the tincture of arnica root of the 1890 Pharmacopœia, which was dropped at the last revision.

The French and German Pharmacopœias both recognize tincture of arnica made from the flowers by maceration, the former directing 20 parts of drug and 100 parts of 60 per cent. alcohol, and the latter 10 parts of drug and 100 parts of 68½ per cent. alcohol.

Tincture of arnica has a yellowish-brown color and the characteristic odor of arnica flowers. If made with a stronger menstruum than diluted alcohol, it will be lighter in color and form a more opalescent mixture with water, containing, no doubt, more resinous matter. In our experience equally perfect exhaustion of the drug may be effected by moistening the powder with about ½ its weight of diluted alcohol, packing very

firmly in a percolator, saturating with menstruum, macerating for 48 hours, and then percolating slowly until the required volume of tincture has been obtained.

Uses.—Tincture of arnica is a popular household remedy, applied externally, either alone or diluted, for bruises, sprains, or local pains. The benefit it produces is probably due to the alcohol. Though rarely employed internally, it may be given in the dose of 10 to 30 minims (0.60–2 Cc.).

TINCTURA AROMATICA, *P. G.*—Aromatic Tincture.

Teinture aromatique, Fr.; *Aromatische Tinktur*, G.

Preparation.—Cassia bark, in coarse powder, 5 parts; ginger, in moderately fine powder, 2 parts; galanga root, in moderately fine powder, clove in moderately fine powder, and Malabar cardamom, crushed, each, 1 part; alcohol (68½ per cent.), 50 parts. Macerate for 7 days, shaking occasionally, and filter.—U. S.

Aromatic tincture has a brownish-red color and a decidedly aromatic odor, and a pungent, strongly spicy taste. It forms a turbid mixture with water.

Uses.—This tincture may be employed as a grateful addition to preparations designed to increase the appetite and promote digestion. The dose is from 1 to 2 drachms (4–8 Cc.).

TINCTURA ASAFŒTIDÆ, *U. S., Br.*—Tincture of Asafetida.

Teinture d'asafœtida, Fr.; *Asanttinktur*, G.

Preparation.—Asafetida, bruised, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Macerate the asafetida in a stoppered container, in a moderately warm place, with 750 Cc. of alcohol, during 3 days, with frequent agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pass enough alcohol through the residue to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of asafetida, macerate 3 avoirdupois ounces and 148 grains of well-bruised asafetida with 12 fluidounces of alcohol for 3 days, shaking frequently; then filter and pass sufficient alcohol through the residue to bring the volume up to 16 fluidounces.

The proportions of other pharmacopœias are: Asafetida, bruised, 4 ounces; alcohol (70 per cent.), sufficient to make 1 imperial pint (20 fluidounces).—Br. Asafetida, 1 part; alcohol (80 per cent.), 5 parts.—Fr. Cod.

Tincture of asafetida has a yellowish brown-red color, and the strong, disagreeable odor of the drug. It is rendered milky on the addition of water. Owing to the inferior quality of much of the commercial asafetida, care should be taken to use only such as is quite free from sand and other impurities, and more than ½ of which is soluble in alcohol.

Tinctura Asafœtidæ Ætherea.—The French Codex recognizes an ethereal tincture of asafetida under the name of *Teinture éthérée d'asafœtida* or *Ethérolé d'asafœtida*, which is made by macerating 1 part of asafetida in 5 parts of a mixture of ether 7 Gm. and alcohol 3 Gm. for 10 days, with occasional agitation, and then filtering.

Uses.—On account of its unpleasant taste, the administration of tincture of asafetida by the mouth is rarely resorted to except in hysterical conditions. The emulsion is a better preparation to be used in enemata to dislodge flatus. The dose is from 10 to 30 minims (0.60–2 Cc.).

TINCTURA AURANTII AMARI, *U. S.*—Tincture of Bitter Orange Peel.

Tinctura aurantii, Br.; P. G.—*Tincture of orange*, E.; *Teinture d'orange amère*, Fr.; *Pomeranzentinktur*, G.

Preparation.—Bitter orange peel, in No. 40 powder, 200 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix alcohol and water in the proportion of 600 Cc. of alcohol to 400 Cc. of water. Moisten the bitter orange peel with 80 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, gradually pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of bitter orange peel, moisten 3 avoirdupois ounces and 148 grains of the powdered peel with 1½ fluidounces of menstruum (alcohol 6 volumes, water 4 volumes), allow the mixture to stand for 6 hours, pack firmly in a percolator, saturate with menstruum until 16 fluidounces of percolate have been obtained.

Fresh bitter orange peel, cut small, 5 ounces; alcohol (90 per cent.), 20 fluidounces. Macerate in a closed vessel for 7 days, frequently agitating. Strain. Press the marc. Mix the expressed and strained liquids, and filter if necessary.—Br.

The German Pharmacopœia directs tincture of orange to be prepared by macerating 1 part of finely-cut bitter orange peel with 5 parts of 68½ per cent. alcohol for 7 days, and then filtering. The French Codex uses the same proportions, but orders 80 per cent. alcohol to be used.

The U. S. bitter tincture of bitter orange peel is not identical with the tincture of orange of the British Pharmacopœia, having a different color and taste. It is greenish brown, and has a somewhat bitter taste, and closely resembles the German tincture. The British tincture has a reddish-yellow color and a pleasant aroma, being made from fresh peel and containing chiefly the volatile oil of bitter orange. It resembles strongly the next following tincture.

Uses.—Tincture of bitter orange peel is employed chiefly as a flavoring ingredient of tonic mixtures. The dose is ½ to 2 drachms (2–8 Cc.).

TINCTURA AURANTII DULCIS, *U. S.*—Tincture of Sweet Orange Peel.

Teinture d'orange douce, Fr.; *Apfelsinenschaalentinktur*, G.

Preparation.—Sweet orange peel, from the fresh fruit, in thin shavings and cut into narrow shreds, 500 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Macerate the sweet orange peel in a stoppered wide-mouthed container, and in a moderately warm place, with 750 Cc. of alcohol, during 48 hours, with frequent agitation; then filter through purified cotton, and when the liquid has been drained off completely, gradually pass enough menstruum through the residue to make 1000 Cc. of tincture; finally filter through paper.—U. S.

To make 1 pint of tincture of sweet orange peel, macerate 8 avoirdupois ounces and 152 grains of fresh peel for 48 hours with 12 fluidounces of alcohol, pass through purified cotton, and then wash the residue with sufficient alcohol to bring the volume up to 16 fluidounces. Instead of cutting the orange peel into narrow shreds, it will be found more convenient to grate the outer rind, and then wash the grater with a little of the alcohol to be used as menstruum.

The present official tincture of sweet orange peel is 2½ times as strong as that of 1890. It has a deep reddish-yellow color, and a strong, fragrant odor of fresh orange peel, and is superior to a solution of the oil of orange in alcohol as a flavoring agent.

Uses.—This tincture is used solely as a flavoring agent in the dose of ½ to 2 drachms (2–8 Cc.).

TINCTURA BELLADONNÆ FOLIORUM, *U. S.*—Tincture of Belladonna Leaves.

Tinctura belladonnæ, Br.—*Tincture of belladonna*, E.; *Teinture de belladone*, Fr.; *Belladonnatinktur*, G.

Preparation.—Belladonna leaves, in No. 60 powder (containing not less than 0.35 per cent. of alkaloids), 100 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 40 Cc. of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 3 hours; then pack it firmly and pour on enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, gradually pouring on diluted alcohol until 1000 Cc. of percolate are obtained.

Tincture of belladonna leaves, when assayed by the process given below, should contain in 100 Cc. 0.035 Gm. of the alkaloids from belladonna leaves.—U. S.

To make 1 pint of tincture of belladonna leaves, moisten 730 grains of the powdered leaves with 5 fluidrachms of diluted alcohol and proceed as above, finally collecting 16 fluidounces of percolate.

Assay of Tincture of Belladonna Leaves.—Transfer 100 Cc. of tincture of belladonna leaves to an evaporating dish and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under FLUIDEXTRACTUM BELLADONNÆ RADICIS (page 652), using the same details as there directed for 10 Cc. of fluidextract of belladonna root, with the exception that the multiplication of the product by 10 must be omitted; the result will represent the weight in grammes of alkaloids contained in 100 Cc. of tincture of belladonna leaves.—U. S.

Take of liquid extract of belladonna root 2 fluidounces; alcohol (60 per cent.), a sufficient quantity. To the liquid extract of belladonna add enough of the alcohol to form 30 fluidounces of tincture; filter after 24 hours' rest. On evaporation to a small bulk and assay by the process given for liquid extract of belladonna root, 100 Cc. of the tincture should yield not less than 0.048 nor more than 0.052 Gm. of alkaloid.—Br.

Tincture of belladonna of the French Codex is made from the leaves with 60 per cent. alcohol, in the proportion of 5 Gm. of leaves for 100 Gm. of finished tincture.

The present official tincture of belladonna leaves is about one-third weaker than that of 1890, besides being standardized to contain 0.00035 Gm. of alkaloid in each cubic centimeter, or about $\frac{1}{50}$ grain in each fluidrachm. It has a deep greenish-brown color, and characteristic narcotic odor. The British tincture, being made from the root, is brownish yellow in color, and is about 50 per cent. stronger than that of the U. S. P.

TINCTURA BELLADONNÆ ÆTHEREA.—The French Codex recognizes an ethereal tincture of belladonna under the name *Teinture éthérée de belladone* or *Éthérolé de belladone*, which is made by exhausting 1 part of belladonna leaves with a menstruum composed of 7 parts of ether and 3 parts of alcohol until 5 parts of tincture have been obtained.

Uses.—This preparation fully represents the properties of the drug. It is given in the dose of 5 to 20 minims (0.30–1.30 Cc.).

TINCTURA BENZOINI, *U. S.*—Tincture of Benzoin.

Tinctura benzoës, P. G.—*Teinture de benjoin*, Fr.; *Benzoëtinktur*, G.; *Tinctura de benjui*, Sp.

Preparation.—Benzoin, No. 40 powder, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Triturate the benzoin with 250 Cc. of alcohol until a uniform magma is obtained. Transfer this to a stoppered container with the aid of 500 Cc. of alcohol, and set it aside in a moderately warm place, shaking frequently during 3 days. Then transfer the mixture to a paper filter, and when the liquid has drained off completely, pour on enough alcohol to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of benzoin, triturate 3 avoirdupois ounces and 148 grains of benzoin with 4 fluidounces of alcohol until a uniform magma is obtained. Transfer to a bottle with the aid of 8 fluidounces of alcohol, and macerate in a moderately warm place for 3 days. After filtering, pour enough alcohol on the residue to bring the volume up to 16 fluidounces.

Macerate benzoin, 1 part, in alcohol, 5 parts.—Fr. Cod., P. G.

The tincture is brownish red, and yields with water a milky mixture having an acid reaction.

LAC VIRGINIS.—*Virgin's milk*, E.; *Lait vaginal*, Fr.; *Jungfernmilch*, G.—is a cosmetic preparation consisting of tincture of benzoin 1 part and rose-water from 20 to 100 parts.

Uses.—Tincture of benzoin was formerly applied to many conditions for which the compound tincture is employed. It is still popularly used in combination with rose-water as a lotion for chapping, sunburn, freckles, and slight eruptions of the skin. Its dose is from 10 to 20 minims (0.60–1.30 Cc.).

TINCTURA BENZOINI COMPOSITA, *U. S., Br.*—Compound Tincture of Benzoin.

Tinctura balsamica, Fr. Cod.; *Balsamum commendatoris, Elixir traumaticum.—Teinture balsamique, Baume du commandeur de Permes*, Fr.; *Persischer Wundbalsam*, G.

Preparation.—Benzoin, in No. 40 powder, 100 Gm.; purified aloes, in No. 50 powder, 20 Gm.; storax, 80 Gm.; balsam of Tolu, 40 Gm.; alcohol, a sufficient quan-

tity to make 1000 Cc. Triturate the benzoin and purified aloes with 250 Cc. of alcohol until a uniform magma is obtained. Transfer this to a stoppered container with the aid of 500 Cc. of alcohol, add the storax and balsam of Tolu, and set the mixture aside in a moderately warm place, shaking it frequently during three days; then transfer it to a a paper filter, and when the liquid has drained off completely, pour on enough alcohol to make 1000 Cc. of tincture.—U. S.

To make 1 pint of compound tincture of benzoin, triturate 730 grains of benzoin in No. 40 powder, 150 grains of purified aloes with 4 fluidounces of alcohol, until a uniform magma is obtained. Transfer this to a stoppered container with the aid of 8 fluidounces of alcohol, add 600 grains of storax and 300 grains of balsam of Tolu, and set the mixture aside in a moderately warm place for 3 days. After filtering, pour enough alcohol on the residue to bring the volume up to 16 fluidounces.

Take of benzoin, in coarse powder, 2 ounces; prepared storax, 1½ ounces; balsam of Tolu, ½ ounce; socotrine aloes, 160 grains; alcohol (90 per cent.), sufficient for 1 pint (imperial). Macerate for 2 days and filter.—Br.

St. Johnswort, 2 parts; angelica root, myrrh, olibanum, and aloes, of each, 1 part; balsam of Tolu and benzoin, of each, 6 parts; alcohol (80 per cent.), 72 parts.—Fr. Cod.

The older pharmacopœias had still more complicated formulas.

The tincture is intended to take the place of numerous preparations formerly employed, as *Wade's*, *Vervain's*, *Saint Victor's*, *Jesuits'*, *Friars'*, *Turlington's*, *Persian*, and *Swedish balsam*. It is of a deep red-brown color, and yields with water a reddish-white opaque mixture having an acid reaction.

Uses.—This preparation is sometimes given as an expectorant in subacute and chronic bronchitis to aid in the expulsion of mucous. Other drugs have supplanted it in the treatment of chronic diarrhœa and catarrh of the urinary organs. Locally, it is useful as a stimulant and protective for ulcers, bed-sores, cracked nipples, and fissures of the lips and anus. The dose is from 20 to 60 minims (1.30–4 Cc.).

TINCTURA BUCHU, *Br.*—Tincture of Buchu.

Teinture de buchu, Fr.; *Buchutinktur*, G.

Preparation.—Take of buchu leaves, in No. 20 powder, 4 ounces; alcohol (60 per cent.) a sufficient quantity. Moisten the powder with 4 fluidounces of the alcohol, and complete the percolation process. The resulting tincture should measure 1 pint (imperial).—Br. Buchu, 1 part; alcohol (80 per cent.), 5 parts.—Fr. Cod.

The first tincture has a greenish-brown, the second a brownish-green, color; both have the odor and taste of the drug.

Uses.—This preparation is not so frequently employed as an infusion in the conditions for which buchu is indicated. The dose is from 1 to 2 drachms (4–8 Cc.).

TINCTURA CALAMI, *P. G.*—Tincture of Calamus.

Teinture d'acore vrai, Fr.; *Kalmustinktur*, G.

Preparation.—Calamus, finely cut, 1 part; alcohol (68½ per cent.), 5 parts. Macerate for 7 days with occasional agitation, then filter.—P. G.

Tincture of calamus has a brownish-yellow color and a pungent, bitter, spicy taste.

Uses.—Tincture of calamus is used as a stomachic and flavoring agent. The dose is 1 to 2 drachms (4–8 Cc.).

TINCTURA CALENDULÆ, *U. S.*—Tincture of Calendula.

Tincture of marigold, E.; *Teinture de souci*, Fr.; *Calendulatinktur*, G.

Preparation.—Calendula, in No. 20 powder, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the calendula with 80 Cc. of alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it very firmly, and pour on enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of calendula, moisten 3 avoirdupois ounces and 148 grains of calendula, in No. 20 powder, with 10 fluidrachms of alcohol, and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

This tincture is not recognized by other pharmacopœias.

Uses.—This tincture is employed as a cooling, soothing application in bruises, sprains, etc.

TINCTURA CALUMBÆ, *U. S., Br.*—Tincture of Calumba.

Tinctura colombo.—Teinture de colombo, Fr.; *Kolombotinktur*, G.

Preparation.—Calumba, in No. 20 powder, 100 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 400 Cc. of water. Moisten the calumba with 100 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 24 hours; then pack it with moderate pressure, pour on enough menstruum to saturate the powder and leave a stratum above it, and allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of calumba moisten 3 avoirdupois ounces and 148 grains of calumba, in No. 20 powder, with 1½ fluidounces of menstruum (alcohol, 6 volumes; water, 4 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

The British Parmacopœia directs tincture of calumba to be made by maceration, the strength being 2 avoirdupois ounces to 20 fluidounces imperial measure, and the menstruum alcohol of 60 per cent.

Colombo, 1 part; alcohol (60 per cent.), 5 parts.—Fr. Cod.

The tincture has a brown-yellow color, and is much less prone to unsightly precipitation than that made with diluted alcohol.

Uses.—Tincture of calumba is an excellent bitter tonic, given to stimulate the appetite and aid digestion. It is one of the bitters that can be added to fluid preparations of iron without causing precipitation and dark discoloration. The dose is ½ to 2 drachms (2–8 Cc.).

TINCTURA CANNABIS INDICÆ, *U. S., Br.*—Tincture of Indian Cannabis.

Tincture of hemp (Indian hemp), E.; *Teinture de chanvre de l'Inde*, Fr.; *Indischhanftinktur*, G.

Preparation.—Indian cannabis, in No. 40 powder, 100 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the Indian cannabis with 50 Cc. of alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it very firmly and pour on enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of Indian cannabis moisten 730 grains of the drug, in No. 40 powder, with 6 fluidrachms of alcohol, and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Extract of Indian hemp, 1 ounce; alcohol (90 per cent.), a sufficient quantity. Dissolve the extract in 18 fluidounces of alcohol, filter, and add sufficient alcohol to bring the volume up to 20 fluidounces, imperial measure.—Br.

The present official tincture is ⅓ weaker than that of 1890, and about ¼ as strong as the British tincture, since Indian cannabis of good quality yields about 12½ per cent. of extract. The tincture of the French Codex is made from the drug with 60 per cent. alcohol, 100 Gm. of the finished tincture representing 20 Gm. of Indian cannabis, but it is doubtful whether the drug is completely exhausted by such weak alcohol.

Uses.—This tincture possesses all the medicinal properties of the crude drug. Being a resinous tincture, when added to aqueous mixtures its resin must be held in suspension by the aid of gum. Because of the uncertain quality of the crude drug, the dose of the tincture is estimated at from 5 to 60 minims (0.30–4 Cc.).

TINCTURA CANTHARIDIS, *U. S., Br.*—Tincture of Cantharides.

Tinctura cantharidum, P. G.—*Teinture de cantharide*, Fr.; *Spanischfliegentinktur*, G.

Preparation.—Cantharides, in No. 60 powder, 100 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the cantharides with 35 Cc. of alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it very firmly and pour on enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of cantharides moisten 730 grains of the powdered cantharides with 5 fluidrachms of alcohol and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Cantharides, in No. 40 powder, ¼ ounce; alcohol (90 per cent.), 1 imperial pint. Prepare the tincture by maceration.—Br.

The tincture has the burning taste and the peculiar odor of cantharides. Made with alcohol, it is of a greenish-yellow color; but diluted alcohol dissolves the dark extractive matter and yields a brown-yellow tincture. The present official tincture of cantharides is twice as strong as that of 1890, representing 0.10 Gm. in each Cc. or about 5¾ grains in each fluidrachm. It is 8 times as strong as the British tincture and of about equal strength with the tinctures of the French and German Pharmacopœias.

Uses.—This is the preparation of cantharides best suited for internal administration. In overdose it will produce all of the irritating toxic symptoms of the crude drug. Its external application in liniments is rarely resorted to, both because its action is slow and because it is apt to induce vesication. The dose of the tincture is from 1 to 10 minims (0.05–0.60.).

TINCTURA CAPSICI, *U. S., Br., P. G.*—Tincture of Capsicum.

Teinture de piment des jardins, Fr.; *Spanischpfeffertinktur*, G.

Preparation.—Capsicum, in No. 50 powder, 200 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 950 Cc. of alcohol with 50 Cc. of water. Moisten the capsicum with 35 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of capsicum moisten 730 grains of capsicum, in No. 50 powder, with 5 fluidrachms of menstruum (alcohol, 95 volumes; water, 5 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

The British Pharmacopœia directs 1 ounce of capsicum to be macerated with 20 fluidounces of 70 per cent. alcohol, the resulting tincture being about ½ as strong as the U. S. P. preparation. The German tincture of capsicum is of about the same strength as our own.

Tincture of capsicum has a light reddish-orange color and the fiery taste of capsicum. The present official tincture is twice as strong as that of 1890.

Uses.—Tincture of capsicum is an efficient preparation of the drug, and is indicated in atonic conditions of the stomach, especially of chronic alcoholism, when a powerful impression upon the gastric mucosa is desired. Topically, it is a rubefacient added to liniments. Diluted, it is employed in gargles for relaxed sore throat. The dose is from 5 to 30 minims (0.30–2 Cc.).

TINCTURA CARDAMOMI, *U. S.*—Tincture of Cardamom.

Teinture de cardamome, Fr.; *Kardamomentinktur*, G.

Preparation.—Cardamom, in No. 30 powder, 200 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the cardamom with 80 Cc. of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient diluted alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of cardamom, moisten 3 avoirdupois ounces and 148 grains of the powdered cardamom with 1¼ fluidounces of diluted alcohol, and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Simple tincture of cardamom is not official in the British, French, or German pharmacopœias. It is of a brownish-yellow color, and has the aromatic odor and spicy taste of cardamom in a marked degree. The present tincture is twice as strong as that of 1890.

Uses.—The compound tincture of cardamom has almost entirely replaced this preparation as a carminative and aromatic. Its dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA CARDAMOMI COMPOSITA, *U. S.*, *Br.*—Compound Tincture of Cardamom.

Teinture de cardamome composée, Fr.; *Zusammengesetzte Kardamomentinktur*, G.

Preparation.—Cardamom, 25 Gm.; Saigon cinnamon, 25 Gm.; caraway, 12 Gm.; cochineal, 5 Gm.; glycerin, 50 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Mix the glycerin with 950 Cc. of diluted alcohol. Reduce the cardamom, Saigon cinnamon, caraway, and cochineal to a No. 40 powder, and macerate in a stoppered container in a moderately warm place with 750 Cc. of the menstruum during 7 days, with occasional agitation; then filter through purified cotton or a plain filter, and when the liquid has drained off completely, pour on the residue, first the remainder of the menstruum, and then sufficient diluted alcohol to make 1000 Cc. of tincture.—U. S.

To make 1 pint of compound tincture of cardamom, mix 185 grains each of cardamom and Saigon cinnamon with 90 grains of caraway and 38 grains of cochineal, all in No. 40 powder, and macerate the mixture with 12 fluidounces of menstruum (diluted alcohol, 95 volumes; glycerin, 5 volumes) in a stoppered container in a moderately warm place during 7 days with occasional agitation. Filter through purified cotton, and pass enough menstruum through the residue to bring the volume up to 16 fluidounces.

The British Pharmacopœia directs ½ ounce each of bruised cardamom and caraway, 2 ounces of commercial raisins freed from seeds, ½ ounce of bruised Ceylon cinnamon, and 55 grains of powdered cochineal to be macerated with 20 fluidounces of 60 per cent. alcohol for 7 days.

Both tinctures have a red color, due to cochineal, and are of an agreeable aromatic odor and taste.

Uses.—This is a deservedly popular tonic, largely used as a pleasant vehicle for other drugs, and possessing valuable carminative and stomachic qualities. The dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA CASCARILLÆ, *Br.*—Tincture of Cascarilla.

Teinture de cascarille, Fr.; *Caskarilltinktur*, G.

Preparation.—Take of cascarilla, in No. 40 powder, 4 ounces; alcohol (70 per cent.), a sufficient quantity. Moisten the powder with 3 fluidounces of the alcohol and complete the percolation process. The resulting tincture should measure 1 pint imperial (20 fluidounces).—Br.

Uses.—Though an efficient tonic and stimulant to the gastro-intestinal tract, this preparation is rarely employed in this country. Its dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA CASTOREI, *Fr. Cod.*—Tincture of Castor.

Teinture de castoreum, Fr.; *Bibergeiltinktur*, G.

Preparation.—Castor, in coarse powder, 10 Gm.; alcohol (80 per cent.), 100 Gm. Macerate in a closed vessel for 10 days with frequent agitation. Express and filter.—Fr. Cod.

The tincture has a deep reddish-brown color, is rendered opalescent by water, and with a larger quantity of water becomes milky, of a dingy brownish-white color, deposits red-brown resinous matter, and on standing becomes nearly colorless and almost transparent; on the addition of excess of ammonia the resin remains undissolved.

TINCTURA CASTOREI ÆTHEREA.—*Ethereal Tincture of Castor.*—The French Codex directs this tincture to be made exactly like the above, except that instead of alcohol a menstruum composed of 7 parts of ether and 3 parts of alcohol is used.

Uses.—Tincture of castor is occasionally given in hysterical disorders, more for a psychic effect than for any sedative qualities that the drug may possess. Its dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA CATECHU COMPOSITA.—Compound Tincture of Catechu.

Tinctura Catechu, Br., P. G.; *Teinture de Cachou*, Fr. Cod.—*Tincture of catechu*, E.; *Katechutinktur*, G.

See TINCTURA GAMBIR COMPOSITA.

The change of title of this well-known preparation in the U. S. Pharmacopœia of 1900 seems unfortunate and hardly justified in view of the fact that recent editions of foreign pharmacopœias recognize Gambir or Pale Catechu under the official title of Catechu. It would perhaps have been better to have retained the old title for the tincture and transferred the title Catechu to the product now usually sold under that name, which is derived from Uncaria or Ourouparia Gambir and not, as heretofore, from Acacia Catechu. Very little if any catechu from Acacia Catechu is now to be found in the market.

Uses.—(See TINCTURA GAMBIR COMPOSITA.)

TINCTURA CHIRATÆ, *Br.*—Tincture of Chiretta.

Tincture of chirata, E.; *Teinture de chirette*, Fr.; *Chirettatinktur*, G.

Preparation.—Chiretta, in No. 40 powder, 2 ounces; alcohol (60 per cent.), a sufficient quantity. Moisten the powder with 2 fluidounces of the alcohol, and complete the percolation process. The resulting tincture should measure 1 imperial pint.—Br.

Uses.—This is used as a bitter tonic in the dose of ½ to 2 drachms (2–8 Cc.).

TINCTURA CHLOROFORMI ET MORPHINÆ COMPOSITA, *Br.*—Compound Tincture of Chloroform and Morphine.

Preparation.—Chloroform, 1½ fluidounces; morphine hydrochloride, 87½ grains; diluted hydrocyanic acid, 1 fluidounce; tincture of capsicum, ½ fluidounce; tincture of Indian hemp, 2 fluidounces; oil of peppermint, 14 minims; glycerin, 5 fluidounces; alcohol (90 per cent.), a sufficient quantity. Mix the chloroform, tincture of capsicum, tincture of Indian hemp, oil of peppermint, and glycerin with 9 fluidounces of the alcohol, and dissolve the morphine hydrochloride in the mixture; add the diluted hydrocyanic acid; then mix with enough of the alcohol to form 1 imperial pint of the compound tincture.—Br.

The above preparation contains in each fluidrachm 4½ minims of chloroform, 3 minims of diluted hydrocyanic acid, 6 minims of tincture of Indian hemp, 1½ minims of tincture of capsicum, and $\frac{6}{11}$ grain of morphine hydrochloride.

Uses.—This tincture resembles in its formula the preparation known as chlorodyne. It is used chiefly to allay abdominal colic and check diarrhœa. The dose is from 10 to 30 minims (0.60–2 Cc.).

TINCTURA CIMICIFUGÆ, *U. S., Br.*—Tincture of Cimicifuga.

Tinctura actææ racemosæ.—Tincture of black cohosh, Tincture of black snakeroot, E.; *Teinture d'actée à grappes*, Fr.; *Cimicifugatinktur*, G.

Preparation.—Cimicifuga, in No. 40 powder, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the cimicifuga with 60 Cc. of alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolator to proceed slowly, pouring on sufficient alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of cimicifuga, moisten 3 avoirdupois ounces and 148 grains of the powdered drug with 1 fluidounce of alcohol, and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

The tincture of the British Pharmacopœia is a much weaker preparation, being made by percolating 2 ounces of cimicifuga with sufficient 60 per cent. alcohol to produce 1 imperial pint of finished tincture.

Owing to the large resin content of cimicifuga, strong alcohol is necessary to insure perfect exhaustion, which, on the other hand, renders the tincture less desirable. Since both a fluid and a powdered extract of cimicifuga are officially recognized, there seems to be little or no need for this preparation.

Uses.—The quantity of alcohol in each dose of this tincture is somewhat disadvantageous. The fluidextract is a better preparation. The dose of the tincture is from ½ to 2 drachms (2–8 Cc.).

TINCTURA CINCHONÆ, *U. S., Br.*—Tincture of Cinchona.

Teinture de quinquina jaune, Fr. Cod.; *Tinctura chinæ*, P. G.; *Tincture cinchonæ flavæ.—Tincture of yellow cinchona*, E.; *Chinatinktur*, G.; *Tintura de quina*, Sp.

Preparation.—Cinchona, in No. 60 powder (yielding not less than 4 per cent. of anhydrous ether-soluble alkaloids), 200 Gm.; glycerin, 75 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 675 Cc. of alcohol and 250 Cc. of water. Moisten the cinchona with 80 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of alcohol and water, made in the same proportions as before, until 1000 Cc. of percolate are obtained.

Tincture of cinchona, when assayed by the process given below, should contain in 100 Cc. 0.75 Gm. of anhydrous ether-soluble alkaloids of cinchona.—U. S.

To make 1 pint of tincture of cinchona moisten 3 avoirdupois ounces and 148 grains of the prescribed cinchona bark with 1¼ fluidounces of menstruum (glycerin, 7½ volumes; alcohol, 67½ volumes; water, 25 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture are obtained.

Assay of Tincture of Cinchona.—Transfer 50 Cc. of tincture of cinchona to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc., transfer the liquid to a bottle having the capacity of about 180 Cc., rinsing the dish with 10 Cc. of diluted alcohol, then assay the resulting liquid by the method given under FLUIDEXTRACTUM CINCHONÆ (p. 657), with the exception that the multiplication of the product should be by 4 instead of 20; the result will represent the weight in grammes of anhydrous ether-soluble alkaloids contained in 100 Cc. of the tincture.—U. S.

Tincture of cinchona of the British Pharmacopœia is made by moistening 4 ounces of red cinchona bark, in No. 40 powder, with 4 fluidounces of alcohol (70 per cent.), setting aside for 24 hours in a closed vessel, and then percolating until 14 fluidounces of percolate have been obtained; the marc is expressed and the liquid added to the percolate; after 24 hours' rest the mixture is filtered and assayed. To the bulk of the

strong tincture sufficient 70 per cent. alcohol is added so that the resulting tincture shall contain 1 Gm. of alkaloids in every 100 Cc.

Uses.—Tincture of cinchona is used as a stomachic and tonic in the dose of ½ to 2 drachms (2–8 Cc.).

TINCTURA CINCHONÆ COMPOSITA, *U. S., Br.*—Compound Tincture of Cinchona.

Tinctura chinæ composita, P. G.; *Huxham's tincture of bark*, E.; *Teinture de quinquina composée, Elixir fébrifuge d'Huxam*, Fr.; *Zusammengesetzte Chinatinktur*, G.

Preparation.—Red cinchona (yielding not less than 5 per cent. of cinchona alkaloids), 100 Gm.; bitter orange peel, 80 Gm.; serpentaria, 20 Gm.; glycerin, 75 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 675 Cc. of alcohol and 250 Cc. of water. Reduce the red cinchona, bitter orange peel, and serpentaria to a No. 60 powder, moisten this powder with 80 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of alcohol and water, made in the same proportions as before, to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of compound tincture of cinchona mix 730 grains of the prescribed red cinchona, 584 grains of bitter orange peel, and 146 grains of serpentaria, all in No. 60 powder, moisten with 1¼ fluidounces of menstruum (glycerin, 7½ volumes; alcohol, 67½ volumes; water, 25 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture are obtained.

The British Pharmacopœia directs 1 ounce of bitter orange peel, well bruised, ½ ounce of serpentaria, in No. 40 powder, 28 grains of cochineal, in powder, and 55 grains of saffron to be macerated with 10 fluidounces of alcohol (70 per cent.) for 7 days, agitating frequently; the mixture is then strained and the marc expressed. After mixing the liquids 10 fluidounces of tincture of cinchona are added and sufficient of the alcohol to produce 1 imperial pint of compound tincture. After standing for 24 hours the tincture is filtered.

While the alkaloidal strength of the two tinctures is about the same, both containing in each Cc. about 0.005 Gm. of anhydrous cinchona alkaloids, there is a marked difference in appearance due to the presence of cochineal and saffron in the British tincture.

Compound tincture of cinchona of the German Pharmacopœia differs markedly from the above, being prepared by maceration with alcohol of about 68 per cent. and representing in 100 parts by weight the soluble constituents of 12 parts of cinchona bark, 4 parts each of bitter orange peel and gentian, and 2 parts of cassia bark.

Uses.—The percentage of cinchona alkaloids in this preparation is too small to permit of its being used as an antiperiodic unless very large doses are given. It is, however, an excellent stimulant to the stomach, to be employed to enhance the appetite, especially during convalescence from fevers. Its dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA CINNAMOMI, *U. S., Br., P. G.*—Tincture of Cinnamon.

Teinture de cannelle, Fr.; *Zimmttinktur*, G.; *Tintura de canela*, Sp.

Preparation.—Saigon cinnamon, in No. 50 powder, 200 Gm.; glycerin, 75 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 675 Cc. of alcohol and 250 Cc. of water. Moisten the Saigon cinnamon with 80 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of alcohol and water, made in the same proportions as before, to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of cinnamon, moisten 3 avoirdupois ounces and 148 grains of Saigon cinnamon, in No. 50 powder, with 1¼ fluidounces of menstruum (glycerin, 7½ volumes; alcohol, 67½ volumes; water, 25 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Ceylon cinnamon, in No. 40 powder, 4 avoirdupois ounces; alcohol (70 per cent.), a sufficient quantity. Moisten the powder with 4 fluidounces of the alcohol, and prepare the tincture by percolation. The resulting tincture should measure 1 imperial pint.—Br.

The German Pharmacopœia directs tincture of cinnamon to be made by maceration with alcohol (68½ per cent.), using 5 parts of cassia bark for every 100 parts of menstruum. Tincture of cinnamon of the French Codex represents 1 part of Ceylon cinnamon in every 5 parts of finished product, and is made with 80 per cent. alcohol.

The tincture has a red-brown color and a sweetish, warmly aromatic, and somewhat astringent taste. It sometimes gelatinizes when the menstruum becomes too weak in alcohol. This is intended to be overcome by the presence of glycerin and greater alcoholic strength in the official formula.

Uses.—Because of its carminative and slight astringent properties, tincture of cinnamon is frequently added to diarrhœa mixtures. Its pleasant taste is also employed to mask less agreeable drugs. The dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA COCCI, *Br.*—Tincture of Cochineal.

Teinture de cochenille, Fr.; *Cochenilletinktur*, G.

Preparation.—Take of cochineal, in powder, 2 ounces; alcohol (45 per cent.), 1 imperial pint. Prepare by maceration.—Br.

The French Codex prescribes 80 per cent. alcohol as a menstruum, using 10 Gm. of cochineal for every 100 Gm. of tincture.

Uses.—This tincture is used solely as a coloring agent.

TINCTURA COLCHICI SEMINIS, *U. S., Br.*—Tincture of Colchicum Seed.

Tinctura colchici, P. G.—*Tincture of colchicum*, E.; *Teinture de colchique*, Fr.; *Zeitlosentinktur*, G.; *Tintura de semilla de colchico*, Sp.

Preparation.—Colchicum seed, in No. 50 powder (containing not less than 0.55 per cent. of colchicine), 100 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 400 Cc. of water. Moisten the colchicum seed with 40 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquor begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of percolate.

Tincture of colchicum seed, when assayed by the process given below, should contain in 100 Cc. 0.05 Gm. of colchicine.—U. S.

To make 1 pint of tincture of colchicum seed, moisten 730 grains of the prescribed seed, in No. 50 powder, with 5 fluidrachms of menstruum (alcohol, 6 volumes; water, 4 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Assay of Tincture of Colchicum Seed.—Transfer 100 Cc. of tincture of colchicum seed to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under FLUIDEXTRACTUM COLCHICI SEMINIS (page 659), with the exception that the multiplication of the product by 10 be omitted; the result will represent the weight in grammes of colchicine contained in 100 Cc. of the tincture.—U. S.

Other pharmacopœias direct: Colchicum seed, 4 ounces; alcohol (45 per cent.), sufficient for 1 imperial pint.—Br. Colchicum seed, 1 part; alcohol (68½ per cent.), 10 parts.—P. G. Colchicum seed, 5 parts; alcohol (60 per cent.), 100 parts.—Fr. Cod.

Uses.—This tincture is an efficient preparation of colchicum, although it is not used as often as the wine. The dose is from 15 to 60 minims (1–4 Cc.). (See COLCHICUM.)

TINCTURA COLOCYNTHIDIS, *P. G.*—Tincture of Colocynth.

Teinture de coloquinte, Fr.; *Koloquinthentinktur*, G.

Preparation.—Colocynth, in coarse powder, 1 part; alcohol, 10 parts. Macerate in a closed vessel for 7 days, frequently agitating; strain with expression, and filter the liquid.—P. G.

Uses.—Colocynth is rarely, if ever, used in this country in the form of the tincture. The dose is from 5 to 30 minims (0.30–2 Cc.). (See COLOCYNTH.)

TINCTURA CONII, *Br.*—Tincture of Conium.

Teinture de ciguë, Fr.; *Schierlingstinktur*, G.

Preparation.—Conium fruit, recently reduced to No. 40 powder, 4 ounces; alcohol (70 per cent.), a sufficient quantity. Moisten the powder with 4 fluidounces of the alcohol, and prepare the tincture by percolation, collecting 1 imperial pint of percolate.

Uses.—The dose of this tincture is from 20 to 60 minims (1.30–4 Cc.).

TINCTURA CROCI, *Br.*—Tincture of Saffron.

Teinture de safran, Fr.; *Safrantinktur*, G.

Preparation.—Saffron, 1 ounce; alcohol (60 per cent.), 1 imperial pint. Prepare by maceration.—Br.

Tincture of saffron of the French Codex is made by macerating 10 Gm. of saffron in 100 Gm. of alcohol (80 per cent.), and hence is about twice as strong as the British tincture.

The tincture has a rich orange-yellow color, and the odor and taste of saffron. It was dropped from the 1900 edition of the U. S. P. The former official tincture was made with diluted alcohol, in the proportion of 10 Gm. to 100 Cc. of menstruum.

Uses.—Tincture of saffron is used chiefly to impart its color to mixtures. The dose is from 1 to 2 drachms (4–8 Cc.).

TINCTURA CUBEBÆ, *Br.*—Tincture of Cubeb.

Teinture de cubèbe, Fr.; *Kubebentinktur*, G.

Preparation.—Cubebs, in powder, 4 ounces; alcohol (90 per cent.), a sufficient quantity. Moisten the powder with 2 fluidounces of the alcohol, and prepare the tincture by percolation, as directed elsewhere. The resulting tincture should measure 1 imperial pint.—Br.

The French Codex directs the tincture to be made by macerating 1000 Gm. of cubebs in 500 Gm. of 80 per cent. alcohol.

Tincture of cubeb has a greenish-brown color, and the characteristic odor and taste of the drug, and, when mixed with water, becomes milky. It is no longer official in the U. S. P.

Uses.—Tincture of cubeb may be employed whenever cubeb is indicated. The dose is from ½ to 2 drachms (2–8 Cc.). (See CUBEBA.)

TINCTURA DIGITALIS, *U. S., Br., P. G.*—Tincture of Digitalis.

Teinture de digitale, Fr.; *Fingerhuttinktur*, G.

Preparation.—Digitalis, in No. 60 powder, 100 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the digitalis with 40 Cc. of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolator to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of digitalis, moisten 730 grains of the powdered drug with 5 fluidrachms of diluted alcohol and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Other pharmacopœias direct: Digitalis leaves, 2½ ounces; alcohol (60 per cent.), sufficient to make 1 imperial pint of tincture by percolation.—Br. Digitalis leaves, 1 part; alcohol (68½ per cent), 20 parts.—P. G. Digitalis leaves, 2 parts; alcohol (60 per cent.), 10 parts.—Fr. Cod.

Tincture of digitalis has a brown-green color, the peculiar odor of the leaves, and a bitter taste. The present official tincture is about ⅓ weaker than that of 1890, representing in each fluidrachm about 5¾ grains of digitalis leaves.

TINCTURA DIGITALIS ÆTHEREA. *Ethereal Tincture of Digitalis.*—This preparation is recognized in the French Codex under the title *Teinture ethérée de digitale* or *ethérolé de digitale*, and is made by exhausting 20 Gm. of the powdered leaves with 100 Gm. of a mixture of ether 7 parts and alcohol 3 parts. It has a dark-green color.

Uses.—Tincture of digitalis contains a smaller quantity of digitonin than the infusion, and for this reason is claimed by some to be less diuretic in its action. Many physicians, however, employ the tincture exclusively, both for its diuretic and its cardiant effect. The dose is from 10 to 30 minims (0.60–2 Cc.), and may be cautiously increased to produce the desired result.

TINCTURA ERGOTÆ AMMONIATA, *Br.*—Ammoniated Tincture of Ergot.

Tinctura secalis cornuti ammoniata.—Teinture ammoniacale de seigle ergoté, Fr.; *Ammoniakalische Mutterkorntinktur*, G.

Preparation.—Ergot, in No. 20 powder, 5 ounces; solution of ammonia, 2 fluidounces; alcohol (60 per cent.), a sufficient quantity. Mix the solution of ammonia with 18 fluidounces of the alcohol; moisten the powder with 2 fluidounces of this mixture and percolate with the remainder; press the marc; mix the expressed liquid with the percolate; add enough of the alcohol to form 1 imperial pint of the tincture. After 24 hours, filter.—Br.

Uses.—The dose of this tincture is from ½ to 2 drachms (2–8 Cc.).

TINCTURA FERRI CHLORIDI, *U. S.*—Tincture of Ferric Chloride.

Tinctura ferri perchloridi, Br.; *Tinctura ferri sesquichloridi.—Tincture of perchloride of iron, Tincture of chloride of iron*, E.; *Teinture de perchlorure de fer*, Fr.; *Eisenchloridtinktur*, G.

A hydro-alcoholic solution of ferric chloride containing not less than 13.28 per cent. of the anhydrous salt, corresponding to 4.6 (4.58) per cent. of metallic iron.—U. S.

Preparation.—Solution of ferric chloride, 350 Cc.; alcohol, a sufficient quantity to make 1000 Cc. Mix the solution with enough alcohol to make 1000 Cc. Let the tincture stand in a closely covered vessel at least three months; then transfer it to glass-stoppered bottles, and keep it protected from light.—U. S.

To make 1 pint of the tincture, mix 5 fluidounces and 288 minims of solution of ferric chloride with sufficient alcohol to produce 16 fluidounces of finished tincture.

Mix strong solution of ferric chloride, 5 fluidounces, with alcohol (90 per cent.), 5 fluidounces, and distilled water, 10 fluidounces.—Br.

The two tinctures are practically alike, except that the first contains free hydrochloric acid, and when it is kept on hand for some time, as directed by the Pharmacopœia, previous to dispensing it, acquires an ethereal odor from the formation of various compounds, resulting from the action upon the alcohol of the free acid, and probably also of the ferric chloride, the latter being reduced to ferrous chloride, more particularly on exposing the tincture to the light.

Inasmuch as the present official solution of ferric chloride is considerably weaker than that of 1890, it became necessary to increase the proportion of solution to be used in making a definite volume of the tincture, in order to maintain the actual strength of the finished product. The 350 Cc. of solution of ferric chloride directed in the above formula correspond about in iron-content to 250 Cc. of the solution of the 1890 Pharmacopœia. When the solution is mixed with alcohol, contraction of volume takes place and the liquid becomes warm, hence after cooling it will be necessary to add more alcohol so as to bring the finished product up to the prescribed volume.

Properties and Tests.—Tincture of ferric chloride is a bright brownish liquid, having a slightly ethereal odor, a very astringent, styptic taste, and an acid reaction.

Its specific gravity is about 1.005 at 25° C. (77° F.). The tincture yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide test-solution, and a white one, insoluble in nitric acid, with silver nitrate test-solution. After the tincture has been exposed for some time to daylight, it yields a greenish or greenish-blue color with potassium ferricyanide test-solution, showing the presence of some ferrous salt, due to reduction. On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the tincture (1 in 10), the crystal should not become colored brown, nor should there be a brownish-black zone developed around it (absence of nitric acid). Evaporate 2.22 Gm. of the tincture to dryness on a water-bath, add 2 Cc. of hydrochloric acid and 5 Cc. of solution of hydrogen dioxide, and again evaporate the mixture to dryness; dissolve the residue in 10 Cc. of water, pour the solution into a glass-stoppered bottle having a capacity of about 100 Cc., rinsing the vessel with 10 Cc. more of water, add 1 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and keep the mixture for half an hour at a temperature of 40° C. (104° F.), then cool, and add a little starch test-solution; it should require not less than 18.3 Cc. of tenth-normal sodium thiosulphate solution to discharge the blue color of the liquid (each Cc. of the volumetric solution used indicating 0.25 per cent. of metallic iron).—U. S. If the solution of ferric chloride contained oxychloride, as is sometimes the case, a yellowish precipitate is apt to form in the tincture, either immediately or upon standing. The presence of oxychloride in the tincture may be tested for by diluting the tincture with 8 times its volume of distilled water and then boiling the mixture, when upon cooling it will remain clear if the impurity be absent, or become turbid if it be present.

Allied Tinctures.—Tinctura Ferri Chlorati Ætherea, P. G. *Tinctura tonico-nervina Bestuscheffii, Liquor anodynus martiatus, Spiritus ferri chlorati œthereus.—Ethereal tincture of ferric chloride,* E.; *Ätherische Chloreisentinktur,* G.—1 part of solution of ferric chloride specific gravity 1.282 (containing 19.9 per cent. $FeCl_3$) is mixed with alcohol 7 parts and ether 2 parts, the mixture exposed to the sunlight until colorless, and afterward kept in partially filled bottles in a shady place until it has acquired a yellow color. During the bleaching process the ferric is reduced to ferrous chloride, ethyl chloride and a little aldehyde being generated through the influence of the nascent chlorine. On exposure to the air the salt is partly oxidized to ferric oxychloride. This is known as *Bestuscheff's tincture.* It has a warm and ferruginous taste, is precipitated black by ammonia, white by silver nitrate, and blue by both ferrocyanide and ferricyanide of potassium, and contains 1 per cent. of iron. 10 Cc. of this tincture, after being agitated with an equal volume of the solution of potassium acetate, should separate on standing 3 Cc. of ethereal liquid.

This tincture represents about 1 per cent. of metallic iron.

Tinctura Ferri Citro-chloridi.—*Tincture of Citro-chloride of Iron.*—This preparation, better known as Tasteless Tincture of Iron, was introduced by Creuse in 1873. It represents very nearly the same amount of metallic iron as the official tincture, but the same is in different combination, and the tincture has a deep green color. While not tasteless, the characteristic taste of the official tincture of iron has been materially modified by the presence of alkali citrate. A process for preparing this tincture may be found in the National Formulary of the American Pharmaceutical Association.

Uses.—Tincture of ferric chloride is one of the most astringent preparations of iron, and applied locally acts as a caustic upon delicate tissues. It is one of the best and most useful preparations to be given as a chalybeate in anæmia and debilitated states, and its acid reaction increases its efficiency as a tonic. The diuretic action of the tincture is not due to the presence of ethers, as is generally held, but probably to the inherent property of the ferric chloride. Like the solution of ferric chloride, the tincture may be used locally as a styptic, but is more often given internally to arrest passive hemorrhages from the kidneys, bladder, and uterus. As a topical application it is serviceable in diphtheria and tonsillitis. Its administration has been found of value in chronic inflammations of mucous membranes, as leucorrhœa, bronchorrhœa, diarrhœa, and gleet. In the treatment of erysipelas no other drug has produced such gratifying results, and by many physicians it is considered a valuable internal remedy in follicular tonsillitis and septic infection, especially that following childbirth. In these conditions it should be given in full doses, well diluted, frequently repeated, 10 to 15 minims (0.60–1 Cc.) every 2 or 3 hours, if the stomach does not rebel. In chronic parenchymatous nephritis it augments the

flow of urine and diminishes the quantity of albumin. Tincture of ferric chloride is usually given in the dose of from 5 to 20 minims (0.30–1.30 Cc.), well diluted with water and taken through a glass tube to prevent injury to the teeth.

TINCTURA FERRI POMATI, *P. G.*—Tincture of Ferrous Malate.

Teinture de malate de fer, Fr.; *Apfelsaure Eisentinktur*, G.

Preparation.—Extract of ferrous malate, 1 part; cinnamon water, 9 parts. Dissolve the extract in the cinnamon water and filter the liquid.—P. G.

Tincture of ferrous malate has a brown-black color and the odor of cinnamon. It is miscible in all proportions with water and has a decided ferruginous taste. It should be borne in mind that the cinnamon water of the German Pharmacopœia is made by distilling 1 part of cassia bark with 1 part of alcohol and sufficient water to obtain 10 parts of distillate, hence it has a slight spirituous odor.

Uses.—This tincture is practically identical with the tinctura ferri pomata of our National Formulary, and is given in the dose of from 5 to 30 minims (0.30–2 Cc.).

TINCTURA GALLÆ, *U. S.*—Tincture of Nutgall.

Tinctura gallarum, P. G.—*Tincture of galls*, E.; *Teinture de noix de galle*, Fr.; *Galläpfeltinktur*, G.

Preparation.—Nutgall, in No. 40 powder, 200 Gm.; glycerin, 100 Cc.; alcohol, a sufficient quantity to make 1000 Cc. Mix the glycerin with 900 Cc. of alcohol; introduce the nutgall, without moistening it, into a glass percolator, shaking down the powder evenly and compactly, and pour on sufficient of the menstruum to saturate it and leave a stratum above it. Allow the percolation to proceed slowly, pouring on the remainder of the menstruum, and then sufficient alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of nutgall introduce 3 avoirdupois ounces and 148 grains of nutgall in No. 40 powder, without previous moistening, into a percolator, shake down evenly and compactly, and percolate with enough menstruum (glycerin, 1 volume; alcohol, 9 volumes) to produce 16 fluidounces of finished product.

The German Pharmacopœia directs that 1 part of coarsely powdered nutgall be macerated with 5 parts of 68½ per cent. alcohol. The French Codex orders the same proportions, but 60 per cent. alcohol.

Nutgall of good quality yields over 60 per cent. of extract. The addition of glycerin is intended to retard the formation of gallic acid. The tincture has a yellowish-brown color, a strongly astringent taste, and an acid reaction, and yields blue-black precipitates with ferric salt.

Uses.—Tincture of galls is rarely given internally, but diluted is used as an astringent application in sore throat and relaxed conditions of the rectum. Its dose by the mouth is from ½ to 1 drachm (2–4 Cc.).

TINCTURA GAMBIR COMPOSITA, *U. S.*—Compound Tincture of Gambir.

Tinctura catechu, Br., P. G.; *Tinctura catechu composita*, U. S. 1890.—*Tincture of catechu*, E.; *Teinture de cachou*, Fr.; *Katechutinktur*, G.

Preparation.—Gambir, in No. 50 powder, 50 Gm.; Saigon cinnamon, in No. 50 powder, 25 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Macerate the gambir and Saigon cinnamon in a stoppered container, in a moderately warm place, with 750 Cc. of diluted alcohol during 48 hours, with frequent agitation; then filter through purified cotton, or a plain filter, and when the liquid has drained off completely, pass enough menstruum through the residue to make 1000 Cc. of tincture.—U. S.

To make 1 pint of compound tincture of gambir macerate 365 grains of gambir and 183 grains of Saigon cinnamon, both in No. 50 powder, with 12 fluidounces of diluted alcohol during 48 hours, frequently shaking the mixture. Filter through cotton and pass enough menstruum through the residue to make 16 fluidounces.

The British Pharmacopœia directs that catechu, in coarse powder, 4 ounces, and Ceylon cinnamon, bruised, 1 ounce, be macerated with 1 imperial pint of 60 per cent. alcohol. The German and French Pharmacopœias both omit the cinnamon, simply macerating 1 part of catechu with 5 parts of 68½ per cent. and 60 per cent. (respectively) alcohol.

The tincture has a dark red-brown color, a strongly astringent taste, and an acid reaction; it does not become milky on the addition of water, produces with ferric salts greenish-black precipitates, and when heated with potassium dichromate becomes brownish-red.

Uses.—This tincture is used almost exclusively as an astringent in diarrhœa of the acute serous form. When the stools contain much mucus the administration of this or any other astringent mixture should be preceded by a purgative, preferably castor oil. The dose is from ½ to 2 drachms (2–8 Cc.) or more.

TINCTURA GELSEMII, *U. S., Br.*—Tincture of Gelsemium.

Teinture de gelsemium, Fr.; *Gelsemiumtinktur*, G.

Preparation.—Gelsemium, in No. 60 powder, 100 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 650 Cc. of alcohol with 350 Cc. of water. Moisten the gelsemium with 35 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of gelsemium moisten 730 grains of the powdered drug with ½ fluidounce of menstruum (alcohol, 6½ volumes; water, 3½ volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

The British Pharmacopœia directs the same proportion of gelsemium and alcohol of 60 per cent. as a menstruum.

Tincture of gelsemium is of a brownish-yellow color, becomes milky when mixed with water, and has the aromatic odor and bitter taste of the drug. The present official tincture is ⅛ weaker than that of 1890, representing about 5¾ grains of gelsemium in each fluidrachm.

Uses.—This is an efficient preparation of the drug, given in the dose of 5 to 15 minims (0.30–1 Cc.). (See GELSEMIUM.)

TINCTURA GENTIANÆ COMPOSITA, *U. S., Br.*—Compound Tincture of Gentian.

Teinture de gentiane composée, Fr.; *Zusammengesetzte Enziantinktur*, G.

Preparation.—Gentian, 100 Gm.; bitter orange peel, 40 Gm.; cardamom, 10 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 400 Cc. of water. Reduce the gentian, bitter orange peel, and cardamom to a No. 40 powder, moisten this powder with 60 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 12 hours; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 12 hours; then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of the tincture.—U. S.

To make 1 pint of compound tincture of gentian mix 730 grains of gentian, 292 grains of bitter orange peel, and 73 grains of cardamom, all in No. 40 powder, moisten with 1 fluidounce of menstruum (alcohol, 6 volumes; water, 4 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

The British Pharmacopœia directs gentian, 2 ounces; bitter orange peel, ¾ ounce, and cardamom, ¼ ounce, all well bruised, to be macerated with 1 imperial pint of 45 per cent. alcohol.

Compound tincture of gentian has a brown yellow-color, an agreeable aromatic odor, and a very bitter taste. It acquires with ferric salts a dark blackish-brown color. The stronger alcoholic menstruum directed in the U. S. P. formula is preferable, because the deposit occurring in the tincture is thereby reduced to a minimum.

Uses.—Compound tincture of gentian is an efficient bitter tonic in atony of the stomach, especially following that of an alcoholic debauch. The dose is from ½ to 2 drachms (2–8 Cc.).

Allied Tinctures.—TINCTURA GENTIANÆ.—*Tincture of gentian*, E.; *Teinture de gentiane*, Fr.; *Enziantinktur*, G. This preparation is official in both the French and German Pharmacopœias. It is made by macerating 1 part of the ground root in 5 parts of 60 per cent. alcohol (68½ per cent. alcohol.—P. G.).

TINCTURA GENTIANÆ ALKALINA.—*Alkaline Tincture of Gentian.*—*Teinture de gentiane alcaline, Elixir amèr de Peyrylhe*, Fr. Cod.; *Alkalische Enziantinktur*, G. It is made by macerating gentian, in coarse powder, 10 parts, crystallized sodium carbonate 3 parts, with 300 parts of alcohol of 60 per cent.

TINCTURA GUAIACI, *U. S.*—Tincture of Guaiac.

Teinture de résine de gayac, Fr.; *Guajaktinktur*, G.

Preparation.—Guaiac, in No, 40 powder, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Macerate the guaiac in a stoppered container in a moderately warm place with 750 Cc. of alcohol during 3 days, with frequent agitation; then filter, and, when the liquid has drained off, pour on enough alcohol to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of guaiac, macerate 3 avoirdupois ounces and 148 grains of coarsely powdered guaiac with 12 fluidounces of alcohol for 3 days, with frequent agitation; then filter, and pass enough alcohol through the filter to bring the volume up to 16 fluidounces.

Since guaiac resin dissolves completely in alcohol with the exception of the impurities, the tincture is conveniently made by maceration. The tincture has a dark brownish-red color, is precipitated by water, and is colored green or blue by ferric chloride and other agents.

Uses.—Tincture of guaiac has been largely used in chronic rheumatism, gout, and amenorrhœa, but its employment is rare at present. Diluted with water, it is occasionally used as a gargle in subacute tonsillitis and pharyngitis. Since it is precipitated on the addition of water, it should be administered in mucilage or syrup. The dose is from ½ to 2 drachms (2–8 Cc.).

Allied Tincture.—TINCTURA GUAIACI LIGNI.—*Tincture of Guaiacum-wood*, E.; *Teinture de gayac*, Fr. Macerate for 10 days guaiacum-wood 10 parts in alcohol (60 per cent.) 50 parts; express and filter.—Fr. Cod.

TINCTURA GUAIACI AMMONIATA, *U. S., Br.*—Ammoniated Tincture of Guaiac.

Teinture de gayac ammoniacale, Fr.; *Ammoniakalische Guajaktinktur*, G.

Preparation.—Guaiac, in No. 40 powder, 200 Gm.; aromatic spirit of ammonia, a sufficient quantity to make 1000 Cc. Macerate the guaiac in a stoppered container in a moderately warm place with 750 Cc. of aromatic spirit of ammonia during 3 days, with frequent agitation; then filter, and when the liquid has drained off, pour on enough aromatic spirit of ammonia to make 1000 Cc. of tincture.—U. S.

To make 1 pint of ammoniated tincture of guaiac, macerate 3 avoirdupois ounces and 148 grains of coarsely powdered guaiac with 12 fluidounces of aromatic spirit of ammonia for 3 days, with frequent agitation; then filter, and pass enough aromatic spirit of ammonia through the filter to bring the volume up to 16 fluidounces.

The British Pharmacopœia directs that guaiacum resin, in powder, 4 ounces, be added to a mixture of strong solution of ammonia, 1½ fluidounces, and alcohol, 16 fluidounces, set aside in a closed vessel for 48 hours, with frequent agitation, and then filtered; oil of lemon, 20 minims, and oil of nutmeg, 30 minims, are then dissolved in the filtrate, and sufficient alcohol passed through the filter to bring the volume of tincture up to 1 imperial pint.

The two formulas yield practically identical tinctures, which resemble tincture of guaiac in appearance, but have an ammoniacal odor and taste.

Uses.—This tincture is the one generally employed when it is desired to administer guaiac. It is supposed to be more efficient than the simple tincture in amenorrhœa and scanty menstruation. Its dose is from ½ to 2 drachms (2–8 Cc.).

Allied Tincture.—DEWEES'S TINCTURE OF GUAIAC.—Digest for a few days powdered guaiacum resin 4 ounces, sodium or potassium carbonate 90 grains, powdered pimento 1 ounce, in diluted alcohol 1 pint. Add spirit of ammonia, if required, in the proportion of 1 or 2 drachms to each 4 fluidounces of the tincture.

TINCTURA HAMAMELIDIS, *Br.*—Tincture of Hamamelis.

Teinture de hamamélis, Fr.; *Hamamelistinktur*, G.

Preparation.—Hamamelis bark, in No. 20 powder, 2 ounces; alcohol (45 per cent.), a sufficient quantity. Moisten the powder with 1 fluidounce of the alcohol, and prepare a tincture by percolation. The resulting tincture should measure 1 imperial pint.—Br.

Uses.—This tincture is rather weak for internal administration. The dose is from 2 to 4 drachms (8–16 Cc.).

TINCTURA HYDRASTIS, *U. S.*, *Br.*—Tincture of Hydrastis.

Teinture de hydrastis, Fr.; *Hydrastistinktur*, G.

Preparation.—Hydrastis, in No. 60 powder (containing not less than 2.5 per cent. of hydrastine), 200 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix alcohol and water in the proportion of 650 Cc. of alcohol and 350 Cc. of water. Moisten the hydrastis with 60 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly, and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, gradually adding menstruum until 1000 Cc. of percolate are obtained.

Tincture of hydrastis, when assayed by the process given below, should contain in 100 Cc. not less than 0.4 Gm. hydrastine.—U. S.

To make 1 pint of tincture of hydrastis, moisten 3 avoirdupois ounces and 148 grains of the prescribed hydrastis with 1 fluidounce of menstruum (alcohol, 65 volumes; water, 35 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Assay of Tincture of Hydrastis.—Transfer 100 Cc. of tincture of hydrastis to an evaporating dish, and evaporate it on a water-bath until the liquid measures about 10 Cc. If any insoluble matter has separated, add sufficient alcohol to dissolve it, and then assay the resulting liquid by the method given under FLUIDEXTRACTUM HYDRASTIS (page 669), using the same details as there directed for 10 Cc. of fluidextract of hydrastis, with the exception that the weight of the residual alkaloids must be multiplied by 2 instead of by 20, as there directed, to give the weight in grammes of hydrastine contained in 100 Cc. of tincture of hydrastis.—U. S.

The tincture of the British Pharmacopœia is of about ½ the strength of the above, and made with 60 per cent. alcohol. It is not standardized to any definite alkaloidal content.

Uses.—This tincture fully represents the remedial properties of the drug. The dose is from ½ to 2 drachms (2–8 Cc.). (See HYDRASTIS.)

TINCTURA HYOSCYAMI, *U. S.*, *Br.*—Tincture of Hyoscyamus.

Teinture de jusquiame, Fr.; *Bilsenkrauttinktur*, G.

Preparation.—Hyoscyamus, recently dried and in No. 60 powder (containing not less than 0.08 per cent. of mydriatic alkaloids), 100 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the hyoscyamus with 40 Cc. of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, gradually adding diluted alcohol until 1000 Cc. are obtained.

Tincture of hyoscyamus, when assayed by the process given below, should contain in 100 Cc. 0.007 Gm. of mydriatic alkaloids.—U. S.

To make 1 pint of tincture of hyoscyamus, moisten 730 grains of the prescribed hyoscyamus with 5 fluidrachms of diluted alcohol, and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Assay of Tincture of Hyoscyamus.—Transfer 100 Cc. of tincture of hyoscyamus to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. If any insoluble matter has separated, add sufficient alcohol to dissolve it, and then assay the resulting liquid by the method given under FLUIDEXTRACTUM BELLADONNÆ RADICIS (page 652), using the same details as there directed for 10 Cc. of fluidextract of belladonna root, with the exception that the multiplication by 10 must be omitted; the result will represent the weight in grammes of alkaloids contained in 100 Cc. of tincture of hyoscyamus.—U. S.

The tincture of the British Pharmacopœia is of about the same strength as the above, and made with 45 per cent. alcohol. It is not standardized, however, to any definite alkaloidal content.

The tincture is greenish-brown, and has the narcotic odor of the leaves and a bitter taste.

Uses.—Tincture of hyoscyamus contains all the virtues of the drug, and is given in the dose of from 10 to 30 minims (0.60–2 Cc.). (See HYOSCYAMUS.)

TINCTURA IODI, *U. S., Br., P. G.*—Tincture of Iodine.

Tinctura iodinii.—Teinture d'iode, Fr.; *Jodtinktur,* G.; *Tintura de yodo,* Sp.

Preparation.—Iodine, 70 Gm.; potassium iodide, 50 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Triturate the iodine and potassium iodide rapidly in a mortar to a coarse powder, and transfer it at once to a graduated bottle. Rinse the mortar with several successive portions of alcohol, and pour the rinsings into the bottle. Then add enough alcohol, shaking the bottle occasionally until the iodine and potassium iodide are dissolved and the finished tincture measures 1000 Cc.

If 5 Cc. of the tincture be mixed with about 25 Cc. of water and titrated with tenth-normal sodium thiosulphate solution, about 27.25 Cc. of tenth-normal sodium thiosulphate solution should be required for complete decolorization (corresponding to about 6.86 Gm. of iodine in 100 Cc.).—U. S.

To make 1 pint of tincture of iodine dissolve 1 avoirdupois ounce and 74 grains of iodine and 365 grains of potassium iodide in sufficient alcohol to produce 16 fluidounces of solution.

Tincture of iodine of the British Pharmacopœia contains considerably less than ½ as much iodine as the U. S. P. preparation. It is made by dissolving ½ ounce each of iodine and potassium iodide in ½ fluidounce of distilled water, and adding to this solution sufficient alcohol to produce 1 imperial pint of tincture.

The French and German Pharmacopœias direct simply the solution of iodine in 90 per cent. alcohol, the former ordering 1 part of iodine for every 12 parts of alcohol, the latter 1 part for every 10 parts.

Tincture of iodine has a deep brown-red color and the odor of iodine. Upon evaporation the U. S. and Br. tinctures will leave a residue of potassium iodide, but the French and German preparations leave no residue. It should be prepared only in small quantities, as the iodine is slowly changed into hydriodic acid. The object of adding potassium iodide is to permit the addition of the tincture to aqueous liquids without precipitation.

Uses.—The properties and uses of this preparation are discussed under IODUM. This tincture is precipitated on the addition of water, and is therefore not well suited for internal administration. The compound solution is preferable. The dose of the tincture is from 1 to 3 minims (0.05–0.20 Cc.). It is sometimes used for obstinate vomiting,

Allied Tinctures.—TINCTURA IODI DECOLORATA.—*Decolorized Tincture of Iodine.*—Digest 610 grains each of iodine and sodium thiosulphate with 1½ fluidounces of distilled water at a gentle heat until a perfect solution is obtained. Then add 2 fluidounces of alcohol, and afterward 1 fluidounce of stronger ammonia-water. Shake until the liquid has become colorless; cool and add enough alcohol to make 16 fluidounces. Set aside in a cold place for a few hours and filter. The solution contains ammonium iodide, ethyl iodide, C_2H_5I, triethylamine hydro-iodide, $N(C_2H_5)_3HI$, together with sodium iodide, sulphate, and tetrathionate: a crystalline precipitate of the latter salt is apt to form upon standing for a short time.

Decolorized tincture of iodine, being simply a solution of iodides, is of no value as a counterirritant, and is an unnecessary preparation

TINCTURA IODI (Churchill).—*Churchill's Tincture of Iodine.*—Dissolve 240 grains of potassium iodide in 4 ounces of distilled water, add 1200 grains of iodine, and, lastly, enough alcohol to make the tincture measure 16 fluidounces. (Churchill's tincture of iodine must not be confounded with *Churchill's iodine caustic*, which is much stronger and is made by dissolving 480 grains of iodine and 960 grains of potassium iodide in 4 fluidounces of distilled water.)

Lugol's iodine caustic is a solution of 1 part each of iodine and potassium iodide in 2 parts of water. *Hebra's iodine caustic* is of the same strength, but glycerin is used in place of water.

TINCTURA IPECACUANHÆ ET OPII, *U. S.*—Tincture of Ipecac and Opium.

Preparation.—Tincture of deodorized opium, 1000 Cc.; fluidextract of ipecac, 100 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Evaporate the tincture of deodorized opium on a water-bath until it weighs 800 Gm. When it has become cold add to it the fluidextract of ipecac; filter the mixture and pass enough diluted alcohol through the filter to make the tincture measure 1000 Cc.

To make 1 pint of tincture of ipecac and opium evaporate 16 fluidounces of tincture of deodorized opium on a water-bath to 13 fluidounces, and when cold add to it 1 fluid ounce and 288 minims of fluidextract of ipecac; filter the mixture, and pass enough diluted alcohol through the filter to bring the volume up to 16 fluidounces.

Uses.—This tincture is supposed to present the virtues of Dover's powder in a liquid form. It is not generally considered as active a diaphoretic as the powder. The dose is from 5 to 20 minims (0.30–1.30 Cc.).

TINCTURA JABORANDI, *Br.*—Tincture of Jaborandi.

Tinctura pilocarpi.—Tincture of pilocarpus, E.; *Teinture de jaborandi*, Fr.; *Jaboranditinktur*, G.

Preparation.—Jaborandi leaves, in No. 40 powder, 4 ounces; alcohol (45 per cent.), a sufficient quantity. Moisten the powder with 2½ fluidounces of the alcohol, and percolate as directed elsewhere. The resulting tincture should measure 1 imperial pint.—Br.

The tincture of the French Codex represents 1 part of jaborandi in every 5 parts of tincture, and is made with 60 per cent. alcohol.

Uses.—The dose of this preparation is from 1 to 3 drachms (4–12 Cc.).

TINCTURA JALAPÆ, *Br.*—Tincture of Jalap.

Teinture de jalap, Fr.; *Jalapentinktur*, G.

Preparation.—Jalap, in No. 40 powder, 4 ounces; alcohol (70 per cent.), a sufficient quantity. Moisten the powder with 2 fluidounces of the alcohol, and, after packing in a percolator, gradually add more menstruum until 12 fluidounces have been collected. Then express the marc and add the expressed liquid to the percolate. After 24 hours' rest, filter. The amount of the resin present in 10 Cc. of the tincture having been determined, enough menstruum is added to the balance of the strong tincture so that the finished product shall contain 1.5 Gm. of the resin in 100 Cc.—Br.

Uses.—Jalap is rarely administered in this country except in powder or resin. This tincture is a useful addition to other purgative liquids. Its dose is from ½ to 1 drachm (2–4 Cc.).

TINCTURA KINO, *U. S., Br.*—Tincture of Kino.

Teinture de kino, Fr.; *Kinotinktur*, G.

Preparation.—Kino, 50 Gm.; purified talc, 10 Gm.; glycerin, 150 Cc.; alcohol, 650 Cc.; water, a sufficient quantity to make 1000 Cc. Mix the glycerin with 200 Cc. of water, and triturate the kino and purified talc with sufficient of the mixture to produce a thin, smooth magma. Transfer this magma by the aid of the remainder of the mixture to a flask, and, having ascertained the weight of the flask and contents, heat it on a water-bath for about 1 hour; allow the flask and contents to cool, and restore the original weight by the addition of sufficient water. Then add the alcohol, mix, and pass the tincture through a filter of purified cotton, keeping the filter well covered.—U. S.

To make 1 pint of tincture of kino, 365 grains of kino and 75 grains of purified talc are rubbed into a smooth magma with a mixture of 2½ fluidounces of glycerin and 3¼ fluidounces of water. Transfer to a flask, and, having ascertained the weight of the flask and contents, heat it on a water-bath for about 1 hour. When cool, restore the original weight by addition of water. Then add 10¼ fluidounces of alcohol and mix. Finally filter through purified cotton.

The tincture of the British Pharmacopœia is twice as strong as the above, and is made by rubbing 2 ounces of kino with a mixture of 3 fluidounces of glycerin and 5 fluidounces of water to smooth paste; after addition of 10 fluidounces of alcohol, the whole is set aside for 12 hours, with frequent agitation, and then filtered through cotton. Sufficient alcohol is passed through the filter to produce 1 imperial pint.

Tincture of kino is conveniently prepared by maceration, and has a dark brown-red color. Made with alcohol and properly preserved, it will remain limpid, but if made with diluted alcohol it will gradually lose its astringency and become gelatinous. The origin of kino, and probably also its age, may influence the tendency to gelatinize.

In our experience tincture of kino keeps remarkably well if preserved in small vials, so as to avoid frequent exposure to the air; we have kept the tincture in well-corked 2-ounce vials for over a year without observing the slightest change.

Uses.—Tincture of kino is employed chiefly as an addition to astringent mixtures given for serous diarrhœa. The dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA KRAMERIÆ, *U. S., Br.*—Tincture of Krameria.

Tinctura ratanhiæ, P. G.—*Tincture of rhatany*, E.; *Teinture de ratanhia*, Fr.; *Ratanhiatinktur*, G.

Preparation.—Krameria, in No. 40 powder, 200 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the krameria with 80 Cc. of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly, and pour on enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient diluted alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of rhatany, moisten 3 avoirdupois ounces and 148 grains of krameria in No. 40 powder, with 5 fluidrachms of diluted alcohol, and proceed as directed above, continuing percolation until 16 fluidounces of percolate have been obtained.

The British and French Pharmacopœias both prepare tincture of krameria with 60 per cent. alcohol, the former using 4 ounces of the drug for 1 imperial pint of tincture to be made by percolation, the latter 1 part of drug for 5 parts of menstruum by weight.

This tincture has a brown-red color and a strongly astringent taste. After having been kept in partly-filled bottles it deposits rhatany-red, and occasionally gelatinizes. It is therefore best prepared in small quantities. In our experience tincture of rhatany keeps very much better if the menstruum contains about ⅛ of its volume of glycerin.

Uses.—Tincture of krameria may be substituted for the tinctures of kino or gambir in the treatment of diarrhœa. Diluted with water, it may be used as a gargle in sore throat and as an astringent injection in gonorrhœa. The dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA LACTUCARII, *U. S.*—Tincture of Lactucarium.

Teinture de lactucarium, Fr.; *Lactucariumtinktur*, G.

Preparation.—Lactucarium, 500 Gm.; glycerin, 250 Cc.; alcohol, purified petroleum benzin, diluted alcohol, each a sufficient quantity to make 1000 Cc. Beat the lactucarium in an iron mortar, with clean sand, to a coarse powder, and introduce it into a bottle; add 2000 Cc. of purified petroleum benzin, cork the bottle tightly, and set it aside for 48 hours, frequently agitating the mixture. Pour the mixture on a double filter, and allow it to drain. Wash the residue by gradually adding 1500 Cc. of purified petroleum benzin, and allow the lactucarium to dry by exposing it to a current of air. When it is dry and free from the odor of benzin, reduce it to powder, using more sand,

if necessary, and pack it moderately in a conical percolator. Mix the glycerin with 200 Cc. of water and 500 Cc. of alcohol, and moisten the powder with 500 Cc. of the mixture. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed very slowly, gradually adding, first the remainder of the menstruum, and then diluted alcohol, until the lactucarium is exhausted. Reserve the first 750 Cc. of the percolate, evaporate the remainder on a water-bath, at a temperature not exceeding 70° C. (158° F.), to 250 Cc., and mix this with the reserved portion. Filter, and add enough diluted alcohol through the filter to obtain 1000 Cc. of the tincture.—U. S.

To make 1 pint of tincture of lactucarium, reduce 8 avoirdupois ounces and 150 grains of lactucarium to a coarse powder with the aid of sand, macerate with 2 pints of purified benzin for 48 hours, shaking frequently, filter and allow to drain, and wash the residue gradually with 1½ pints of purified benzin. Allow the lactucarium to dry in a current of air, and when all odor of benzin has disappeared, reduce it to powder, using more sand, if necessary, and proceed as directed above, using first a mixture of 4 fluidounces of glycerin, 3¼ fluidounces of water, and 8 fluidounces of alcohol, and finally diluted alcohol; reserve the first 12 fluidounces of percolate, and evaporate the remainder to 4 fluidounces, and mix with the reserve portion. Filter if necessary.

Since tincture of lactucarium is intended chiefly for the preparation of the syrup, it is desirable that a liquid be obtained which shall give a clear mixture with syrup, and as lactucarium contains objectionable inert matter in the form of caoutchouc, the treatment with benzin (suggested by Lemberger in 1875) is directed for its removal. The subsequent percolation of the powder mixed with sand presents no difficulty, as the active bitter principles are soluble in the menstruum ordered, but the percolate should be collected in very slow drops. Each Cc. of the tincture represents 0.5 Gm. of the drug.

Uses.—The medicinal virtues of lactucarium are too feeble to justify the trouble necessary to prepare this tincture. The dose is from 20 to 60 minims (1.30–4 Cc.).

TINCTURA LAVANDULÆ COMPOSITA, *U. S.*, *Br.*—Compound Tincture of Lavender.

Spiritus lavandulæ compositus.—Compound spirit of lavender, Lavender drops, E.; *Teinture de lavande composée,* Fr.; *Zusammengesetzte Lavendeltinktur,* G.

Preparation.—Oil of lavender flowers, 8 Cc.; oil of rosemary, 2 Cc.; Saigon cinnamon, 20 Gm.; cloves, 5 Gm.; nutmeg, 10 Gm.; red saunders, 10 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Reduce the Saigon cinnamon, cloves, nutmeg, and red saunders to a No. 50 powder, and macerate this powder for 3 days in a mixture of 750 Cc. of alcohol and 250 Cc. of water, in which liquid the oils have been dissolved. Then filter through purified cotton or a plain filter, and, when the liquid has drained off completely, pass enough of a mixture of alcohol and water, made in the same proportions as before, through the residue on the filter to make 1000 Cc. of tincture.—U. S.

To make 1 pint of compound tincture of lavender, mix 146 grains of Saigon cinnamon, 37 grains of cloves, 74 grains each of nutmeg and red saunders, all reduced to a No. 50 powder, and macerate the mixture with 16 fluidounces of menstruum (alcohol, 3 volumes; water, 1 volume), in which have been dissolved 1 fluidrachm of oil of lavender flowers and 15 minims of oil of rosemary, for 3 days, then filter through cotton and drain, passing enough menstruum through the residue to bring the volume up to 16 fluidounces.

Take of oil of lavender 1½ fluidrachms; oil of rosemary, 10 minims; cinnamon-bark, bruised, nutmeg, bruised, each 150 grains; red sandal-wood, 300 grains; alcohol (90 per cent.), 2 pints (imperial). Macerate the cinnamon, nutmeg, and red sandal-wood in the spirit for 7 days in a closed vessel, with occasional agitation; then strain and press, dissolve the oils in the strained tincture, filter, and add sufficient rectified spirit to make 2 pints.—Br.

The tincture of the first formula is stronger in volatile oils and aromatics than that made by the British formula. Both have a red color, form opalescent mixtures with water, and, if prepared from good materials, have an agreeable odor and a strong but pleasant aromatic taste.

Uses.—This pleasant aromatic preparation is largely employed both in regular and domestic medicine to allay nausea, gastric distress, and flatulence. The dose is from 30 to 60 minims (2–4 Cc.), administered usually on some sugar or in sweetened water.

TINCTURA LIMONIS CORTICIS, *U. S.*—Tincture of Lemon Peel.

Tinctura Limonis, Br.—*Tincture of lemon*, E.; *Teinture de zeste de citron*, Fr.; *Citronenschalentinktur*, G.

Preparation.—Lemon peel, from the fresh fruit, in thin shavings and cut into narrow shreds, 500 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Macerate the lemon peel in a stoppered, wide-mouthed container, and in a moderately warm place, with 750 Cc. of alcohol during 48 hours, with frequent agitation; then filter through purified cotton, and when the liquid has drained off completely, gradually pour on enough menstruum to make 1000 Cc. of tincture, and filter through paper.—U. S.

To make one pint of the tincture, macerate 8 avoirdupois ounces and 150 grains of shredded or grated fresh lemon peel with 12 fluidounces of alcohol for 48 hours, as directed above, finally passing enough alcohol through the residue to bring the volume up to 16 fluidounces.

Tincture of lemon of the British Pharmacopœia is about ½ as strong as the above, and is made by macerating 5 ounces of finely-cut fresh lemon peel with 1 imperial pint of 90 per cent. alcohol.

This preparation is intended to replace the spirit of lemon of the 1890 Pharmacopœia. It is a much stronger tincture, and has a very much finer flavor.

Uses.—Tincture of lemon peel is used chiefly as a flavoring agent. The dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA LOBELIÆ, *U. S., P. G.*—Tincture of Lobelia.

Teinture de lobélie enflée, Fr.; *Lobeliatinktur*, G.

Preparation.—Lobelia, in No. 50 powder, 100 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the lobelia with 40 Cc. of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient diluted alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of lobelia, moisten 730 grains of the powdered drug with 5 fluidrachms of diluted alcohol, and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

Other pharmacopœias direct: Lobelia, 1 part; alcohol (68 per cent.), 10 parts.—P. G. Lobelia, 1 part; alcohol (60 per cent.), 5 parts.—Fr. Cod.

The present official tincture of lobelia is of exactly ½ the strength of the tincture of 1890, representing about 5¾ grains of the drug in each fluidrachm. It has a greenish-brown color, a somewhat heavy odor, and a bitter and acrid taste.

Uses.—This is the preparation of lobelia nearly always employed. Its dose as an expectorant is from 10 to 20 minims (0.60–1.30 Cc.). To relieve asthmatic attacks it should be given in the dose of from 1 to 2 drachms (4–8 Cc.) every hour or two until it causes nausea or relieves the spasmodic condition. (See LOBELIA.)

TINCTURA LOBELIÆ ÆTHEREA, *Br.*—Ethereal Tincture of Lobelia.

Teinture éthérée de lobélie enflée, Fr.; *Ätherische Lobelientinktur*, G.

Preparation.—Lobelia, in No. 40 powder, 4 ounces; spirit of ether, a sufficient quantity. Moisten the powder with 2 fluidounces of spirit of ether, and prepare the tincture by percolation, as explained elsewhere. The resulting tincture should measure 1 imperial pint.—Br.

This preparation has a decided ethereal odor, and is of a brownish-green color.

Uses.—This preparation is considered more efficacious than the simple tincture in the treatment of asthma. The dose is from 5 to 20 minims (0.30–1.30 Cc.).

TINCTURA LUPULI, *Br.*—Tincture of Hops.

Tinctura humuli.—Teinture de houblon, Fr.; *Hopfentinktur*, G.

Preparation.—Hops, 4 ounces; alcohol (60 per cent.), 1 imperial pint. Prepare the tincture by maceration.—Br.

Tincture of hops is of a yellowish-brown color, and has the peculiar odor and strong taste of the drug.

Uses.—The dose of this tincture is from 1 to 2 drachms (4–8 Cc.). (See HUMULUS.)

TINCTURA MOSCHI, *U. S.*—Tincture of Musk.

Teinture de musc, Fr.; *Moschustinktur*, G.

Preparation.—Musk, 5 Gm.; alcohol, 45 Cc.; water, 45 Cc.; diluted alcohol, a sufficient quantity to make 100 Cc. Triturate the musk with the water, a little at a time, until a smooth mixture is obtained; transfer this mixture to a bottle and allow it to stand 24 hours; add the alcohol and macerate the mixture for 6 days, occasionally shaking it. Then filter through a plain paper filter, and when the liquid has drained off completely, pass enough diluted alcohol through the filter to make 100 Cc. of tincture.—U. S.

To make 2 fluidounces of tincture of musk, use 46 grains of musk, 7 fluidrachms each of water and alcohol, and diluted alcohol, a sufficient quantity, proceeding as directed above.

Neither the British nor the German Pharmacopœia recognizes this preparation, but the tincture of musk of the French Codex is nearly twice as strong as that of the U. S. P., and is made with 80 per cent. alcohol, containing 10 Gm. of musk in 100 Gm. of finished product.

Strong alcohol yields a light-brown tincture, which becomes slightly opalescent with water; but weak alcohol produces a dark-brown tincture, which has a strong odor of musk and remains clear on the addition of water.

Uses.—This preparation will be found convenient for the rare occasions in which musk is used medicinally. The dose is from ½ to 2 drachms (2–8 Cc.). (See MOSCHUS.)

TINCTURA MYRRHÆ, *U. S., Br., P. G.*—Tincture of Myrrh.

Teinture de myrrhe, Fr.; *Myrrhentinktur*, G.

Preparation.—Myrrh, in moderately coarse powder, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Macerate the myrrh in a stoppered container, and in a moderately warm place, with 750 Cc. of alcohol during 3 days, with frequent agitation; then filter through purified cotton or a plain paper filter, and, when the liquid has drained off completely, pour on enough menstruum to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of myrrh, macerate 3 avoirdupois ounces and 148 grains of coarsely powdered myrrh with 12 fluidounces of alcohol for 3 days, with frequent agitation; then filter through a plain paper filter, and pass enough alcohol through the residue to bring the volume up to 16 fluidounces.

Other pharmacopœias direct: Myrrh, 4 ounces; alcohol (90 per cent.), sufficient to make 1 imperial pint of tincture.—Br. Myrrh, 1 part; alcohol, 5 parts.—P. G. Myrrh, 1 part; alcohol (80 per cent.), 5 parts.—Fr. Cod.

Tincture of myrrh is a brownish-yellow or reddish-yellow liquid having the balsamic odor of myrrh and a bitter aromatic taste. On the addition of water it yields a precipitate of resin.

Uses.—Tincture of myrrh is used nearly always as a local application. In full strength it is applied as a stimulant and protective agent to chronic, sloughing ulcers. Diluted with water in the proportion of about 1 part to 20, it is used in the treatment of stomatitis, spongy gums, relaxed uvula, and sore throat. It is rarely given internally. The dose is from 10 to 30 minims (0.60–2 Cc.).

TINCTURA NUCIS VOMICÆ, *U. S., Br.*—Tincture of Nux Vomica.

Tinctura strychni, P. G.—*Teinture de noix vomique*, Fr.; *Brechnusstinktur, Krähenaugentinktur*, G.

Preparation.—Extract of nux vomica (containing 5 per cent. of strychnine), 20 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Dissolve the extract of nux vomica in a sufficient quantity of a mixture of alcohol and water, made in the proportion of 750 Cc. of alcohol and 250 Cc. of water, to make the solution measure 1000 Cc., and filter through a well-covered paper filter.

Tincture of nux vomica, when assayed by the process given below, should contain in 100 Cc. 0.1 Gm. of strychnine.—U. S.

To make 1 pint of tincture of nux vomica, dissolve 146 grains of the prescribed extract of nux vomica in 14 fluidounces of menstruum (alcohol, 3 volumes; water, 1 volume), filter through paper, and wash the filter with sufficient menstruum to bring the volume up to 16 fluidounces.

Assay of Tincture of Nux Vomica.—Transfer 100 Cc. of tincture of nux vomica to a porcelain dish, evaporate it to dryness on a water-bath, and assay the resulting extract by the method given under EXTRACTUM NUCIS VOMICÆ (page 606), using the same details as there directed for 2 Gm. of extract of nux vomica, with the exception that the multiplication by 50 be omitted; the result will represent the weight in grammes of strychnine contained in 100 Cc. of tincture of nux vomica.—U. S.

Liquid extract of nux vomica, 2 fluidounces; distilled water, 3 fluidounces; alcohol (90 per cent.), a sufficient quantity. Mix the liquid extract of nux vomica with the distilled water, and add sufficient alcohol to produce 12 fluidounces. Finally filter. 100 Cc. of the tincture, when assayed, should yield not less than 0.24 Gm. nor more than 0.26 Gm. of strychnine.—Br.

The French and German Pharmacopœias direct the tincture to be made by maceration direct from the nux vomica seed, the former ordering 1 part of drug for 5 parts of 80 per cent. alcohol, and the latter 1 part of drug for 5 parts of 68½ per cent. alcohol. The German Pharmacopœia demands that if 50 Gm. of the tincture be assayed by the process given, an alkaloidal content of not less than 0.251 Gm. of total alkaloids shall be found to be present in 100 Gm.

Tincture of nux vomica has a yellowish color and a very bitter taste, and becomes opalescent when mixed with water. The different official tinctures do not agree in strength: thus the U. S. tincture, which is about ⅓ weaker than the tincture of 1890, is less than ½ as strong as the British tincture, and also somewhat weaker than the German tincture. It contains in each Cc. 0.001 Gm., or in each fluidrachm between $\frac{1}{18}$ and $\frac{1}{17}$ grain of strychnine.

Uses.—Tincture of nux vomica is an excellent preparation to be used when it is desired to add the drug to mixtures. The dose is from 5 to 20 minims (0.30–1.30 Cc.).

TINCTURA OPII, *U. S., Br.*—Tincture of Opium.

Tinctura opii simplex, P. G.—*Teinture d'extrait d'opium*, Fr. Cod.; *Tinctura extracti opii, Tinctura thebaica, Tinctura meconii.—Laudanum*, E.; *Teinture thébaïque*, Fr.; *Einfache Opiumtinktur*, G.; *Tintura de extracto de opio*, Sp.

Preparation.—Granulated opium (containing 12 to 12.5 per cent. of crystallizable morphine), 100 Gm.; alcohol, water, diluted alcohol, each a sufficient quantity to make 1000 Cc. Heat 400 Cc. of water to boiling, and pour it on the granulated opium contained in a tared vessel, weigh, and stir occasionally during 12 hours; then restore the original weight by the addition of cold water, add 400 Cc. of alcohol, pour the mixture into a bottle, and continue the maceration for 48 hours, occasionally shaking. Transfer the mixture to a percolator, return the first portion of the percolate until it runs through clear, and, when the liquid ceases to drop, continue the percolation slowly, pouring on sufficient diluted alcohol until 1000 Cc. are obtained.

Tincture of opium, when assayed by the process given below, should contain in 100 Cc. not less than 1.2 nor more than 1.25 Gm. of crystallized morphine.—U. S.

To make 1 pint of tincture of opium, mix 730 grains of the prescribed opium with 6½ fluidounces of boiling water in a tared dish and weigh; stir frequently during 12

hours, and restore the original weight by addition of cold water, transfer to a bottle, add 6½ fluidounces of alcohol, shake well, and macerate for 48 hours. Transfer the mixture to a percolator, allow percolation to go on slowly, and, when all liquid has disappeared from the surface, pour on sufficient diluted alcohol to bring the total volume of percolate up to 16 fluidounces.

Assay of Tincture of Opium.—Tincture of opium, 100 Cc.; ammonia-water, 3.5 Cc.; alcohol, ether, water, lime-water, each a sufficient quantity. Transfer 100 Cc. of tincture of opium to an evaporating dish and evaporate it on a water-bath to about 20 Cc., add 40 Cc. of water, mix thoroughly, and set the liquid aside for 1 hour, occasionally stirring to disintegrate the resinous flakes adhering to the dish. Then filter the liquid and wash the filter and residue with water until all soluble matter is extracted, collecting the washings separately. Evaporate in a tared dish, first, the washings to a small volume, then add the first filtrate and evaporate the whole to a weight of 14 Gm. Determine the morphine in this extract by the method given under OPIUM (page 1126, beginning with the word "Rotate" in the first paragraph), using the same details as there directed for 10 Gm. of opium, with the exception that the final multiplication by 10 be omitted. The result will represent the weight in grammes of crystallized morphine yielded by 100 Cc. of the tincture.—U. S.

The British Pharmacopœia directs a process similar to the above, using the same menstruum, and preparing from 3 ounces of opium a strong tincture, which is then assayed, and from the results of the assay the amount of diluted alcohol is calculated necessary to be added to the strong tincture in order to bring the strength of the finished product up to the official requirement, namely, that each Cc. shall contain 0.0075 Gm. of anhydrous morphine, or 0.75 Gm. in 100 Cc.

The French Codex orders 10 Gm. of extract of opium to be dissolved in 120 Gm. of 60 per cent. alcohol. No alkaloidal standard is prescribed.

Tincture of opium of the German Pharmacopœia is made by macerating 15 parts of opium with a mixture of 70 parts each of water and 68½ per cent. alcohol. It contains in 100 Gm. 1 to 1.2 Gm. of morphine, and as its specific gravity is given as 0.976 the strength corresponds nearly with that of the U. S. preparation.

Opium readily yields its active constituents to water, and the preliminary treatment of the drug with hot water is intended to facilitate complete exhaustion by the hydro-alcoholic menstruum used subsequently. The tincture has a deep reddish-brown color and the characteristic narcotic odor and bitter taste of opium. The official U. S. P. preparation contains in each fluidrachm very nearly ¾ grain of crystallized morphine.

Uses.—This is the preparation of opium which is used as an addition to anodyne liniments, poultices, etc. The tincture of deodorized opium is preferable for internal administration, because it is free from narcotine to which the nausea following the use of the drug is attributed. The dose is from 5 to 20 minims (0.30–1.30 Cc.).

TINCTURA OPII AMMONIATA, *Br.*—Ammoniated Tincture of Opium.

Teinture d'opium ammoniacale, Fr.; *Ammoniakalische Opiumtinktur*, G.

Preparation.—Tincture of opium, 3 fluidounces; benzoic acid, 180 grains; oil of anise, 1 fluidrachm; solution of ammonia, 4 fluidounces; alcohol (90 per cent.), a sufficient quantity. Dissolve the oil of anise and the benzoic acid in 12 fluidounces of the alcohol; then add the tincture of opium and solution of ammonia, and mix well. Filter and add enough alcohol to form 1 imperial pint of the tincture.—Br.

This preparation is very much weaker in morphine than the preceding tincture, representing in each fluidounce about 5 grains of opium containing 10 per cent. of anhydrous morphine. It contains the alkaloids of opium in solution in a free state, and is very similar to the preparation formerly known as *Scotch Paregoric Elixir*.

Uses.—This preparation corresponds to paregoric, and is used for the same purposes, in the dose of ½ to 1 drachm (2–4 Cc.).

TINCTURA OPII CAMPHORATA, *U. S.*—Camphorated Tincture of Opium.

Tinctura camphoræ composita, Br.; *Élixir parégorique*, Fr. Cod.; *Tinctura opii benzoica*, P. G.; *Elixir paregoricum, Tinctura extracti opii camphorata.—Paregoric, Paregoric elixir*, E.; *Teinture d'opium camphrée*, Fr.; *Benzoësäurehaltige Opiumtinktur*, G.

Preparation.—Powdered opium, 4 Gm.; benzoic acid, 4 Gm.; camphor, 4 Gm.;

oil of anise, 4 Cc.; glycerin, 40 Cc.; diluted alcohol, 900 Cc. Place all the ingredients in a stoppered container and macerate for 3 days with frequent agitation: then filter the mixture through a well-covered paper filter, adding sufficient diluted alcohol through the filter to make 1000 Cc. of tincture.—U. S.

To make 1 pint of paregoric macerate powdered opium, 30 grains; benzoic acid, 30 grains; camphor, 30 grains; oil of anise, 30 minims; and 5 fluidrachms of glycerin with 15 fluidounces of diluted alcohol for 3 days with frequent agitation; filter and pass enough diluted alcohol through the residue to bring the volume up to 16 fluidounces.

Tincture of opium, 585 minims; benzoic acid, 40 grains; camphor, 30 grains; oil of anise, 30 minims; alcohol (60 per cent.), a sufficient quantity. Having dissolved the benzoic acid, camphor, and oil of anise in 18 fluidounces of the alcohol add the tincture of opium and, finally, sufficient of the alcohol to make 1 imperial pint of the tincture.—Br.

Other pharmacopœias direct: Opium, powdered, 1 part; anethol, 1 part; camphor, 2 parts; benzoic acid, 4 parts; alcohol (68½ per cent.), 192 parts.—P. G. Extract of opium, 3 Gm.; benzoic acid, 3 Gm.; oil of anise, 3 Gm.; camphor, 2 Gm.; alcohol (60 per cent.), 650 Gm.—Fr. Cod.

Camphorated tincture of opium has a brownish-yellow color, an anise-like and camphoraceous odor, a sweetish, aromatic, somewhat pungent and slightly bitter taste, and an acid reaction. Upon the addition of water it turns milky, owing to the precipitation of the oil of anise, benzoic acid, and camphor. Each Cc. of the official tincture represents 0.004 Gm., or each fluidrachm very nearly ¼ grain, of opium and a like quantity of camphor and benzoic acid.

Uses.—Paregoric possesses anodyne and carminative properties, and is largely employed to relieve abdominal pain due to flatus, to check diarrhœa, to allay cough, and as a mild sedative for infants. The dose is from 1 to 4 drachms (4–16 Cc.).

TINCTURA OPII DEODORATI, *U. S.*—Tincture of Deodorized Opium.

Teinture d'opium sans odeur, Fr.; *Desodorirte Opiumtinktur*, G.

Preparation.—Granulated opium (containing 12 to 12.5 per cent. of crystallized morphine), 100 Gm.; purified petroleum benzin, 75 Cc.; alcohol, 200 Cc.; water, a sufficient quantity to make 1000 Cc. Heat 500 Cc. of water to boiling, and pour it on the granulated opium contained in a suitable vessel, stirring the mixture frequently during 24 hours. Then transfer the mixture to a percolator, return the first portion of the percolate until it runs through clear, and, when the liquid ceases to drop, continue the percolation with water until the opium is exhausted. Concentrate the percolate by evaporation on a water-bath until it measures 150 Cc., and, when cooled, shake it frequently and vigorously for 10 minutes with 65 Cc. of the purified petroleum benzin. Separate the benzin, repeat the shaking out for a few minutes with the remainder of the benzin, and, having carefully and completely separated this second portion of benzin, evaporate the remaining liquid in a warm place spontaneously until the odor of benzin has disappeared, removing the last traces by the heat of a water-bath. Mix the deodorized liquid so obtained with 600 Cc. of water, filter the mixture through a paper filter, and, having mixed the alcohol with the filtrate, wash the filter with sufficient water to make 1000 Cc. of tincture.—U. S.

To make 1 pint of the tincture, macerate 730 grains of the prescribed opium with 8 fluidounces of water, previously heated to boiling, for 24 hours, stirring the mixture frequently. Then proceed as directed above, and, when the opium is exhausted, concentrate the percolate to 2½ fluidounces, and when cold add 1 fluidounce of purified petroleum benzin and agitate vigorously for 10 minutes. Transfer to a separator and draw off the aqueous fluid, and again shake the same with 2 fluidrachms of the benzin. Again separate the benzin and drive off the last traces by the heat of a water-bath. To the deodorized liquid add 9 fluidounces of water, filter, add 3¼ fluidounces of alcohol to the filtrate, and pass enough water through the filter to bring the volume of finished tincture up to 16 fluidounces.

Assay of Tincture of Deodorized Opium.—If 100 Cc. of tincture of deodorized opium be assayed by the process given under TINCTURA OPII, it should yield from 1.2 to 1.25 Gm. of crystallized morphine.—U. S.

The present tincture of deodorized opium differs from previous preparations mainly in the use of purified petroleum benzin in place of ether, whereby deodorization is effected equally well and the narcotine is permitted to remain in solution. It is now claimed that narcotine is not the nauseating principle in opium, and that instead of being objectionable it is in reality a desirable constituent of the drug. Although the treatment of the concentrated infusion of opium with purified benzin is much less objectionable than with ether, as no annoying emulsion is formed, it is nevertheless undesirable on account of the persistent odor of the benzin. If deodorized opium, in fine or granulated powder, be used, the resulting infusion simply requires concentration, addition of the alcohol and filtration, and thus the process is greatly simplified.

Another unobjectionable method for preparing the tincture is to follow the suggestion of F. T. Gordon (1900), which consists in exhausting 730 grains of standard opium with water, concentrating the infusion to 8 fluidounces on a water-bath, and while still hot adding 2½ ounces of paraffin in small pieces. When the paraffin has melted, the mixture is thoroughly stirred for 10 to 15 minutes until the paraffin no longer seems to darken in color. After cooling, the hardened paraffin crust is broken and washed with a little cold water, the washings being added to the deodorized liquid. The mixture is filtered through paper, enough water passed through the filter to bring the volume, after addition of 3¼ fluidounces of alcohol, up to 16 fluidounces. We have found this method very satisfactory.

It must be borne in mind that the present tincture is somewhat weaker than that of 1890, due to the fact that the morphine standard for opium has been slightly lowered in the 1900 Pharmacopœia. At present tincture of deodorized opium should contain not less than 0.012 nor more than 0.0125 Gm. of crystallized morphine in each Cc., or nearly ¾ grain in each fluidrachm.

Uses.—This is the preferable fluid preparation of opium to be given internally, because it is less apt to cause nausea. The dose is from 5 to 20 minims (0.30–1.30 Cc.).

Allied Preparations.—Liquor Opii Compositus. Opium is exhausted with water, the infusion concentrated, precipitated by alcohol, the clear liquid evaporated to a small bulk equal in weight to that of the opium, and agitated with ether. The aqueous liquid, freed from the ether, is diluted with 1 part of its own weight of water, filtered, mixed with 1 part of stronger alcohol, and diluted with water to 5 parts. A portion of this is assayed, and the whole liquid is then mixed with the remaining ingredients in such proportions that 30 Cc., or 1 fluidounce, shall contain 6 grains of morphine, 1 Cc. of chloroform, 2 Cc. of acetic ether, and 13 Cc. of stronger alcohol, the remaining liquid being water. As originally suggested by Dr. Squibb, this preparation contained 4 grains of morphine in the fluidounce, but after the appearance of the Pharmacopœia of 1880 this amount was increased to 6 grains. (For details see *Amer. Jour. Phar.*, 1870, page 47.)

Battley's Sedative Drops.—Three ounces of extract of opium are dissolved in 30 ounces of hot water, and the solution filtered and mixed with 6 ounces of alcohol. This preparation is about 50 per cent. stronger than those above described.

TINCTURA PHYSOSTIGMATIS, *U. S.*—Tincture of Physostigma.

Teinture de fève du Calabar, Fr.; *Kalabarbohnentinktur*, G.

Preparation.—Physostigma, in No. 50 powder (containing 0.15 per cent. of ether-soluble alkaloids), 100 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the physostigma with 40 Cc. of alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient alcohol to obtain 1000 Cc. of tincture.

Tincture of physostigma, when assayed by the process given below, should contain in 100 Cc. 0.014 Gm. of the ether-soluble alkaloids from physostigma.—U. S.

To make 1 pint of tincture of physostigma, moisten 730 grains of the prescribed physostigma with 5 fluidrachms of alcohol, and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

Assay of Tincture of Physostigma.—Transfer 100 Cc. of tincture of physostigma to a porcelain dish, evaporate it to dryness on a water-bath, and assay the resulting extract by the method given under Extractum Physostigmatis (page 609), using the same details as

there directed for 1 Gm. of extract of physostigma, with the exception that the product must be multiplied by 2 instead of 200; the result will represent the weight in grammes of ether-soluble alkaloids from physostigma contained in 100 Cc. of tincture of physostigma.—U. S.

The present tincture of physostigma is about ⅓ weaker than that of 1890. It has a pale brownish-yellow color, and should be preserved in small, well-stoppered vials, protected against light, on account of the sensitiveness of the alkaloidal salts, when in solution, to the influence of air and light. Each Cc. of the tincture represents 0.00014 Gm. of the ether-soluble alkaloids, or each fluidrachm about $\frac{1}{120}$ grain.

Uses.—This tincture possesses all the medicinal virtues of the drug, and is given in the dose of 10 to 30 minims (0.60–2 Cc.).

TINCTURA PIMPINELLÆ, *P. G.*—Tincture of Pimpinell.

Teinture de grand boucage, Fr.; *Bibernelltinktur*, G.

Preparation.—Pimpinell root, cut moderately fine, 1 part; alcohol (68½ per cent.), 5 parts. Macerate for 7 days, strain and express; finally filter the mixed liquids. —P. G.

Tincture of pimpinell has a brownish-yellow color and a disagreeable acrid taste.

Uses.—Tincture of pimpinell is not used in this country. It is employed in Germany as a carminative, diuretic, and emmenagogue in the dose of ½ to 1 drachm (2–4 Cc.).

TINCTURA PODOPHYLLI, *Br.*—Tincture of Podophyllum.

Teinture de résine de podophyllum, Fr.; *Podophyllintinktur*, G.

Preparation.—Resin of podophyllum, 320 grains; alcohol (90 per cent.), a sufficient quantity. Add the resin of podophyllum to 18 fluidounces of alcohol and let the mixture stand, with occasional agitation, for 24 hours; then filter and pass enough alcohol through the filter to bring the volume of filtrate up to 1 imperial pint.—Br.

This tincture is simply a solution of resin of podophyllum in strong alcohol, representing 2 grains of the resin in each fluidrachm.

Uses.—This tincture may be given whenever podophyllum is indicated. The dose is from 1 to 2 drachms (4–8 Cc.).

TINCTURA PRUNI VIRGINIANÆ, *Br.*—Tincture of Virginian Prune.

Teinture d'écore de cerisier, Fr.; *Wildkirschenrindentinktur*, G.

Preparation.—Virginian prune bark, in No. 20 powder, 4 ounces; alcohol (90 per cent.), 12½ fluidounces; distilled water, 7½ fluidounces. After mixing the powder with the water, it is set aside for 24 hours; the alcohol is then added and the tincture prepared by maceration.—Br.

Uses.—This preparation is useful when it is desired to give wild cherry for its stomachic, tonic properties. Its dose is from 1 to 2 drachms (4–8 Cc.).

TINCTURA PYRETHRI, *U. S., Br.*—Tincture of Pyrethrum.

Tincture of pellitory, E.; *Teinture de pyrèthre*, Fr.; *Bertramwurzeltinktur*, G.

Preparation.—Pyrethrum, in No. 50 powder, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the pyrethrum with 80 Cc. of alcohol, transfer it to a percolator, and without pressing the powder allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of pyrethrum, moisten 3 avoirdupois ounces and 148 grains of the powdered drug with 10 fluidrachms of alcohol, and proceed as directed above, allowing percolation to continue until 16 fluidounces of percolate have been obtained.

Other pharmacopœias direct: Pyrethrum root, in No. 40 powder, 4 ounces; alcohol (70 per cent.)—Br. Pyrethrum root, 1 part; alcohol (80 per cent.), 5 parts.—Fr. Cod.

Tincture of pyrethrum has a brownish-yellow color and a very acrid taste, and on the addition of water becomes opalescent and milky.

Uses.—Tincture of pyrethrum is never given internally, but is used as a stimulant application in paralysis of the tongue, uvula, and pharynx.

TINCTURA QUASSIÆ, *U. S., Br.*—Tincture of Quassia.

Teinture de quassie amère, Fr.; *Quassiatinktur*, G.

Preparation.—Quassia, in No. 50 powder, 200 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 350 Cc. of alcohol with 650 Cc. of water. Moisten the quassia with 60 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of quassia moisten 3 avoirdupois ounces and 148 grains of the powdered drug with 1 fluidounce of menstruum (alcohol, 35 volumes; water, 65 volumes), and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

The British Pharmacopœia directs that the tincture be prepared by macerating 2 ounces of rasped quassia with 1 imperial pint of alcohol (45 per cent.). The French tincture is of the same strength.

Tincture of quassia has a light brownish-yellow color and a persistently bitter taste. It differs from most bitter tinctures in not being colored black or green by ferric salts, since it contains no tannin. The present tincture is twice as strong as that of 1890.

Uses.—Tincture of quassia is used as a bitter tonic, usually in combination with similar preparations. Diluted with water, it is sometimes employed in enema to destroy threadworms, but the infusion is better for this purpose. The dose is from 15 to 60 minims (1–4 Cc.).

TINCTURA QUILLAJÆ, *U. S.*—Tincture of Quillaja.

Tincture of soap-bark, E.; *Teinture d'écorce de quillaya*, Fr.; *Seifenrindentinktur*, G.

Preparation.—Quillaja, coarsely ground, 200 Gm.; alcohol, 350 Cc.; water, a sufficient quantity to make 1000 Cc. Boil the quillaja in a covered vessel with 800 Cc. of water for 15 minutes, strain while hot, and wash the residue on the strainer with 200 Cc. of water, previously heated to boiling. Then evaporate the strained liquid to 600 Cc., allow it to cool, add the alcohol, and set it aside for 12 hours. Decant the clear liquid, filter it through paper, then pour the residue on the filter, and, when the liquid ceases to drop, wash the filter with sufficient water to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of quillaja, boil 3 avoirdupois ounces and 148 grains of coarsely-ground soap-bark with 13 fluidounces of water for 15 minutes, strain while hot, and wash the residue with 3 fluidounces of water. Evaporate the strained liquid to 9½ fluidounces, cool, and add 5½ fluidounces of alcohol and set aside for 12 hours. Filter and wash the residue in the filter with sufficient water to obtain 16 fluidounces of tincture.

The British Pharmacopœia directs tincture of soap-bark to be made by moistening 1 ounce of quillaja, in No. 20 powder, with ½ fluidounce of alcohol (60 per cent.), and macerating for 24 hours, to percolate with the same menstruum until 1 imperial pint of tincture has been obtained.

Uses.—This tincture may be used for the purposes mentioned under QUILLAJA.

TINCTURA QUININÆ, *Br.*—Tincture of Quinine.

Teinture de quinine, Fr.; *Chinintinktur*, G.

Preparation.—Take of quinine hydrochloride 175 grains; Tincture of orange, 1 pint (imperial). Dissolve the quinine hydrochloride in the tincture.—Br.

Uses—This preparation is unnecessary. The dose is from 1 to 2 drachms (4–8 Cc.) as a bitter tonic.

TINCTURA QUININÆ AMMONIATA, *Br.*—Ammoniated Tincture of Quinine.

Teinture ammoniacale de quinine, Fr.; *Ammoniakhaltige Chinintinktur*, G.

Preparation.—Quinine sulphate, 175 grains; solution of ammonia, 2 fluidounces; alcohol (60 per cent.), 18 fluidounces. Mix the solution of ammonia with the alcohol and add the quinine sulphate; shake until a clear solution is obtained, then set aside for 3 days and filter.—Br.

Uses.—This combination is supposed to be of particular service as a tonic in nervous exhaustion. The dose is from ½ to 1 drachm (2–4 Cc.).

TINCTURA RHEI, *U. S.*—Tincture of Rhubarb.

Tinctura rhei composita.—Compound tincture of rhubarb, Br.; *Teinture de rhubarbe*, Fr.; *Rhabarbertinktur*, G.

Preparation.—Rhubarb, 200 Gm.; cardamom, 40 Gm.; glycerin, 100 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 500 Cc. of alcohol and 400 Cc. of water. Reduce the rhubarb and cardamom to a No. 40 powder and moisten it with 90 Cc. of the menstruum; transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 12 hours; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of alcohol and water, made in the same proportions as before, to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of rhubarb, mix 3 avoirdupois ounces and 148 grains of rhubarb, and 300 grains of cardamom, both in No. 40 powder, moisten with 1½ fluidounces of menstruum (alcohol, 5 volumes; glycerin, 1 volume; water, 4 volumes), and proceed as directed above, allowing percolation to continue, pouring on diluted alcohol after 16 fluidounces of original menstruum have been used until 16 fluidounces of tincture have been obtained.

The British Pharmacopœia directs that 18 fluidounces of tincture be made by percolation with alcohol (60 per cent.) from rhubarb 2 ounces, and ¼ ounce each of cardamom and coriander; this is set aside for 48 hours, filtered, and then mixed with 2 fluidounces of glycerin.

Tincture of rhubarb has a deep reddish-brown color, and the odor and taste of rhubarb, modified slightly by the cardamom. It becomes turbid when mixed with water, and deposits on standing, which latter tendency is materially reduced by the presence of glycerin. The present tincture contains twice as much rhubarb and cardamom as that of 1890.

Uses.—Tincture of rhubarb fully represents the properties of the drug, but is rarely employed. The dose as a purgative is from ½ to 1 ounce (16–30 Cc.); as a stomachic, from ½ to 1 drachm (2–4 Cc.).

Allied Tinctures.—TINCTURA RHEI AQUOSA, P. G.—*Aqueous tincture of rhubarb*, E.; *Wässerige Rhabarbertinktur*, G. Take of rhubarb, cut into thin pieces, 100 parts; powdered borax, potassium carbonate, each 10 parts; add boiling distilled water, 900 parts, and after 15 minutes alcohol, 90 parts; macerate for 1 hour, express slightly, and to 850 parts of liquid add cinnamon-water, 150 parts.

TINCTURA RHEI VINOSA, P. G.—*Vinous tincture of rhubarb*, E.; *Weinige Rhabarbertinktur*, G. Take of rhubarb, cut into slices, 8 parts; cardamom, bruised, 1 part; bitter orange peel, finely cut, 2 parts; sherry wine, 100 parts. Macerate for 7 days and filter. In the filtrate dissolve ⅐ of its weight of sugar.

TINCTURA RHEI AROMATICA, *U. S.*—Aromatic Tincture of Rhubarb.

Teinture de rhubarbe aromatique, Fr.; *Aromatische Rhabarbertinktur*, G.

Preparation.—Rhubarb, 200 Gm.; Saigon cinnamon, 40 Gm.; cloves, 40 Gm.; nutmeg, 20 Gm.; glycerin, 100 Cc.; alcohol, water, diluted alcohol, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 500 Cc. of alcohol and 400 Cc. of

water. Reduce the rhubarb, Saigon cinnamon, cloves, and nutmeg to a No. 40 powder, and moisten it with 90 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand for 12 hours; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of alcohol and water, made in the same proportions as before, to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of aromatic tincture of rhubarb, mix 3 avoirdupois ounces and 148 grains of rhubarb, 300 grains each of Saigon cinnamon and cloves, and 150 grains of nutmeg, all in No. 40 powder, with 1½ fluidounces of menstruum (alcohol, 5 volumes; glycerin, 1 volume; water, 4 volumes), proceed as directed above, and allow percolation to continue, pouring on diluted alcohol after 16 fluidounces of original menstruum have been used, until 16 fluidounces of tincture have been obtained.

This tincture, intended for preparing aromatic syrup of rhubarb, has a dark red-brown color, a pleasant aromatic odor, and a spicy and bitter taste. When mixed with syrup or aqueous fluids, it becomes turbid, which may be overcome by the previous addition of a little borax or alkali carbonate.

Uses.—This preparation may be used for the same purposes as the aromatic syrup when saccharine solutions are not desirable. The dose is from 15 to 60 minims (1–4 Cc.).

TINCTURA SANGUINARIÆ, *U. S.*—Tincture of Sanguinaria.

Tincture of bloodroot, E.; *Teinture de sanguinaire*, Fr.; *Blutwurzeltinktur*, G.

Preparation.—Sanguinaria, in No. 60 powder, 100 Gm.; acetic acid, 20 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 400 Cc. of water. Moisten the sanguinaria with the acetic acid and 30 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of sanguinaria, moisten 730 grains of the powdered drug with 2½ fluidrachms of acetic acid and ½ fluidounce of menstruum (alcohol, 6 volumes; water, 4 volumes), and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

Tincture of sanguinaria has a rich brownish-red color and the bitter, acrid taste of the drug. The addition of acetic acid not only facilitates the extraction of the alkaloidal constituents of the sanguinaria, but also materially aids in preventing or retarding precipitation. The present tincture is ⅛ weaker than that of 1890, representing in each Cc. 0.10 Gm., or in each fluidrachm about 5¾ grains, of sanguinaria.

Uses.—This tincture contains all the virtues of sanguinaria. The dose as an expectorant is from 10 to 30 minims (0.60–2 Cc.). In the dose of 1 drachm (4 Cc.) or more it is emetic.

TINCTURA SCILLÆ, *U. S., Br., P. G.*—Tincture of Squill.

Teinture de Scuille, Fr.; *Meerzwiebeltinktur*, G.

Preparation.—Squill, in No. 20 powder, 100 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water. Macerate the squill with 600 Cc. of the menstruum, in a closed vessel, in a moderately warm place for 3 days, occasionally stirring, and express strongly. Repeat this operation with 300 Cc. of menstruum, macerating 1 day before expression; and, finally, macerate the residue for 6 hours in sufficient menstruum to make the united expressed liquids measure about 1000 Cc. Express as before, mix the expressed liquids, filter through paper, and pass sufficient menstruum through the filter to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of squill, macerate 730 grains of squill, in No. 20 powder,

with 9½ fluidounces of menstruum (alcohol, 3 volumes; water, 1 volume) for 3 days and express strongly. Again macerate with 4½ fluidounces of menstruum for 1 day and express; finally macerate the residue for 6 hours with sufficient menstruum to make the united liquids measure 16 fluidounces. Express as before, mix the liquids, filter, and pass sufficient menstruum through the filter to make 16 fluidounces.

Other pharmacopœias direct: Squill, 4 ounces; alcohol (60 per cent.), 1 imperial pint.—Br. Squill, 100 Gm.; alcohol (60 per cent.), 500 Gm.—Fr. Cod. Squill, 1 part; alcohol (68½ per cent.), 5 parts.—P. G.

Tincture of squill has a light yellow color and the nauseous bitter taste of the drug. The strongly alcoholic menstruum is necessary to avoid extraction of much inert mucilaginous matter. The present tincture is ⅓ weaker than that of 1890.

Uses.—This tincture fully represents the diuretic and expectorant qualities of squill, and is given in the dose of 10 to 30 minims (0.60–2 Cc.).

TINCTURA SENEGÆ, *Br.*—Tincture of Senega.

Teinture de polygala de Virginie, Fr.; *Senegatinktur*, G.

Preparation.—Senega, in No. 40 powder, 4 ounces; alcohol (60 per cent.), a sufficient quantity. Moisten the powder with 4 fluidounces of the alcohol and prepare the tincture by percolation. The resulting tincture should measure 1 imperial pint.—Br.

Uses.—Tincture of senega possesses no advantages over the syrup or fluidextract. The dose is from ½ to 1 drachm (2–4 Cc.).

TINCTURA SENNÆ COMPOSITA, *Br.*—Compound Tincture of Senna.

Elixir salutis.—Teinture de séné composée, Fr.; *Zusammengesetzte Sennatinktur*, G.

Preparation.—Take of senna, broken small, 4 ounces; raisins, freed from seeds, 2 ounces; caraway-fruit, bruised, coriander-fruit, bruised, each ½ ounce; alcohol (45 per cent.), 1 pint. Prepare 1 pint (imperial) of tincture by maceration.—Br.

Uses.—This preparation is employed for the same purposes as the confection of senna. The dose is from 1 to 4 drachms (4–16 Cc.).

TINCTURA SERPENTARIÆ, *U. S., Br.*—Tincture of Serpentaria.

Tincture of serpentary, Br.; *Teinture de serpentaire*, Fr.; *Schlangenwurzeltinktur*, G.

Preparation.—Serpentaria, in No. 50 powder, 200 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 650 Cc. of alcohol with 350 Cc. of water. Moisten the serpentaria with 60 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of serpentaria, moisten 3 avoirdupois ounces and 148 grains of the ground drug with 1 fluidounce of menstruum (alcohol, 65 volumes; water, 35 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

The British Pharmacopœia directs that 4 ounces of ground serpentaria be moistened with 4 fluidounces of alcohol (70 per cent.), and the tincture prepared by percolation. The resulting tincture should measure 1 imperial pint.

Tincture of serpentaria has a brownish-yellow color and the characteristic camphoraceous odor and taste of the drug. The present tincture is twice as strong as that of 1890, representing in each Cc. 0.20 Gm., or in each fluidrachm about 12 grains, of serpentaria.

Uses.—Tincture of serpentaria is rarely prescribed alone, but in combination with other tonic drugs to promote their absorption and increase their effects. The dose is from ½ to 2 drachms (2–8 Cc.).

TINCTURA STRAMONII, *U. S., Br.*—Tincture of Stramonium.

Tincture of stramonium leaves, E.; *Teinture des feuilles de stramoine*, Fr.; *Stechapfelblättertinktur*, G.

Preparation.—Stramonium, in No. 60 powder (containing not less than 0.35 per cent. of mydriatic alkaloids), 100 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the stramonium with 40 Cc. of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 3 hours; then pack it firmly and pour on enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, gradually pouring on diluted alcohol until 1000 Cc. are obtained.—U. S.

Tincture of stramonium, when assayed by the process given below, should contain in 100 Cc. 0.03 Gm. of mydriatic alkaloids from stramonium.—U. S.

To make 1 pint of tincture of stramonium, moisten 730 grains of the prescribed stramonium leaves with 5 fluidrachms of diluted alcohol and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

Assay of Tincture of Stramonium.—Transfer 100 Cc. of tincture of stramonium to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Belladonnæ Radicis* (page 652), using the same details as there directed for 10 Cc. of fluidextract of belladonna root, with the exception that the multiplication by 10, as there directed, be omitted; the result will represent the weight in grammes of alkaloids contained in 100 Cc. of tincture of stramonium.—U. S.

The British Pharmacopœia directs that 4 ounces of coarsely ground stramonium leaves be moistened with 4 fluidounces of alcohol (45 per cent.), and the tincture prepared by percolation. The resulting tincture should measure 1 imperial pint. The French Codex orders 1 part of stramonium leaves and 5 parts of 60 per cent. alcohol.

Tincture of stramonium has a greenish-brown color and a heavy narcotic odor. The present tincture differs from that of 1890 in being made from the leaves instead of the seed. Each Cc. contains 0.0003 Gm., or each fluidrachm about $\frac{1}{50}$ grain, of the mydriatic alkaloids of the drug.

Uses.—Tincture of stramonium contains all the virtues of the drug, and may be used whenever stramonium is indicated, whether internally or externally. The dose is from 5 to 20 minims (0.30–1.30 Cc.).

TINCTURA STROPHANTHI, *U. S., Br., P. G.*—Tincture of Strophanthus.

Teinture des semences de strophantus, Fr.; *Strophanthussamentinktur*, G.

The present tincture of strophanthus is twice as strong as that of 1890.—U. S.

Preparation.—Strophanthus, in No. 60 powder, 100 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 650 Cc. of alcohol with 350 Cc. of water. Moisten the strophanthus with 50 Cc. of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of strophanthus, moisten 730 grains of the powdered seed with 6 fluidrachms of menstruum (alcohol, 65 volumes; water, 35 volumes), and proceed as directed above, continuing percolation until 16 fluidounces of tincture have been obtained.

Strophanthus seeds, in No. 30 powder, $\frac{1}{2}$ ounce; alcohol (70 per cent.), a sufficient quantity. Pack the powder in a percolator; moisten it with 1 fluidrachm of the alcohol; set aside for 48 hours; pour on successive quantities of the alcohol, allowing percolation to proceed slowly, until 10 fluidounces of percolate have been obtained; filter and add sufficient alcohol to produce 1 imperial pint of the tincture.—Br.

The German Pharmacopœia directs 1 part of strophanthus seeds, in moderately fine powder, to be macerated with 10 parts of alcohol (68½ per cent.).

The color of tincture of strophanthus will vary with the menstruum employed; if pure alcohol be used, the color will be greenish-yellow, whereas the official menstruum yields a brownish-yellow tincture. Its taste is very bitter. When freshly made it is apt to be cloudy, and gradually deposits fatty matter, slowly becoming brighter. Strophanthus seeds contain considerable fixed oil, which can be removed by ether, but a simpler plan is that suggested by Scoville and Loewe (1899). The tincture of strophanthus is placed in a flask and then buried in a mixture of crushed ice and salt, and allowed to remain there for 2 hours. The temperature rapidly sinks to —14 C. (6.8 F.), and at the end of the prescribed time an abundant semiflocculent grayish sediment will have formed, which is removed by filtration through paper in a funnel kept packed in ice and salt. The resulting product is bright in appearance, and leaves no fatty stain when evaporated on bibulous paper.

Each Cc. of tincture of strophanthus represents 0.100 Gm., or each fluidrachm about 5¾ grains, of the drug. The British tincture is ¼ as strong.

Uses.—This is the preparation of strophanthus nearly always employed. The dose is from 3 to 15 minims (0.20–1 Cc.).

TINCTURA SUMBUL, *Br.*—Tincture of Sumbul.

Teinture de sumbul, Fr.; *Sumbultinktur*, G.

Preparation.—Sumbul, bruised, 2 ounces; alcohol (70 per cent.), 1 imperial pint. Prepare the tincture by maceration.—Br.

Uses.—The dose of this tincture is from 1 to 4 drachms (4–16 Cc.).

TINCTURA TOLUTANA, *U. S., Br.*—Tincture of Tolu.

Teinture de baume de Tolu, Fr.; *Tolubalsamtinktur*, G.

Preparation.—Balsam of tolu, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Macerate the balsam of tolu in 900 Cc. of alcohol, shaking frequently until dissolved; then filter through paper, and wash the filter with sufficient alcohol to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of tolu, macerate 3 avoirdupois ounces and 148 grains of balsam of tolu with 15 fluidounces of alcohol, shaking frequently until dissolved; then filter through paper, and wash the filter with sufficient alcohol to bring the volume of the filtrate up to 16 fluidounces.

Other pharmacopœias direct: Balsam of tolu, 2 ounces; alcohol (90 per cent.), a sufficient quantity to make 1 imperial pint of tincture.—Br. Balsam of tolu, 1 part; alcohol (80 per cent.), 5 parts.—Fr. Cod.

Tincture of tolu has a yellowish color and a pleasant balsamic odor. It becomes milky on the addition of water, due to precipitation of resin. The present tincture is twice as strong as that of 1890.

Uses.—This tincture is sometimes used as a flavoring ingredient in expectorant mixtures. The dose is from 15 to 60 minims (1–4 Cc.). It is decomposed by aqueous solutions, the resin being precipitated.

TINCTURA VALERIANÆ, *U. S., P. G.*—Tincture of Valerian.

Teinture de valériane, Fr.; *Baldriantinktur*, G.

Preparation.—Valerian, in No. 60 powder, 200 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water. Moisten the valerian with 60 Cc. of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of valerian, moisten 3 avoirdupois ounces and 148 grains of the ground valerian with 1 fluidounce of menstruum (alcohol, 3 volumes; water,

1 volume), and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

Other pharmacopœias direct: Valerian, 100 Gm.; alcohol (60 per cent.), 500 Gm.—Fr. Cod. Valerian, 1 part; alcohol (68½ per cent.), 5 parts.—P. G.

Tincture of valerian is of a brown or reddish-brown color, varying with somewhat the variety of valerian employed, and has the characteristic odor and taste of the drug. On the addition of water it becomes opalescent and turbid.

Uses.—This tincture possesses all the properties of valerian, and is found useful as a sedative in hysterical disorders and as a rapidly acting stimulant in certain low states occurring during the course of acute febrile affections. The dose is from ½ to 2 drachms (2–8 Cc.).

Allied Tincture.—TINCTURA VALERIANÆ ÆTHEREA.—*Ethereal tincture of valerian*, E.; *Teinture éthérée de valériane*, Fr.; *Aetherische Baldriantinktur*, G.—Valerian, 1 part; spirit of ether, 5 parts.—P. G. Valerian, 2 parts; ether (sp. gr. 0.724), 7 parts; alcohol, 3 parts.—Fr. Cod. It is of a yellow or brownish-yellow color, and becomes opalescent and turbid on the addition of water.

TINCTURA VALERIANÆ AMMONIATA, *U. S., Br.*—Ammoniated Tincture of Valerian.

Teinture de valériane ammoniacale, Fr.; *Ammoniakalische Baldriantinktur*, G.

Preparation.—Valerian, in No. 60 powder, 200 Gm.; aromatic spirit of ammonia, a sufficient quantity to make 1000 Cc. Moisten the valerian with 60 Cc. of aromatic spirit of ammonia, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough aromatic spirit of ammonia to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient aromatic spirit of ammonia to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of ammoniated tincture of valerian, moisten 3 avoirdupois ounces of the ground drug with 1 fluidounce of aromatic spirit of ammonia and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

The British Pharmacopœia directs the tincture to be prepared by macerating valerian in No. 40 powder, 4 ounces, with a mixture of oil of nutmeg 30 minims, oil of lemon 20 minims, solution of ammonia 2 fluidounces, and alcohol (60 per cent.) 18 fluidounces.

Ammoniated tincture of valerian has a brown color and the odor and taste of valerian and ammonia.

Uses.—This preparation is more largely used than the simple tincture, especially in the treatment of hysterical females. The dose is from 15 to 60 minims (1–4 Cc.).

TINCTURA VANILLÆ, *U. S.*—Tincture of Vanilla.

Teinture de vanille, Fr.; *Vanilletinktur*, G.

Preparation.—Vanilla, cut into small pieces and bruised, 100 Gm.; sugar, in coarse powder, 200 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 650 Cc. of alcohol with 350 Cc. of water. Macerate the vanilla in 500 Cc. of the mixture for 12 hours; then drain off the liquid and set it aside. Transfer the vanilla to a mortar, beat it with the sugar into a uniform powder, then pack it in a percolator and pour upon it the reserved liquid. When this has disappeared from the surface, continue the percolation by pouring on gradually sufficient menstruum to make 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of vanilla, macerate 730 grains of vanilla beans, cut small and bruised, with 8 fluidounces of menstruum (alcohol, 65 volumes; water, 35 volumes) for 12 hours, and decant the liquid. Beat the residue with 3 avoirdupois ounces and 148 grains of sugar into a uniform powder, pack in a percolator and pour upon the reserved liquid. When this has passed through, pour on more of the menstruum and continue percolation until 16 fluidounces of tincture have been obtained.

The French Codex directs tincture of vanilla to be prepared by macerating 10 Gm. of cut vanilla bean with 100 Gm. of 80 per cent. alcohol for 10 days, and then expressing.

If prepared from prime vanilla bean, the above tincture will be an excellent preparation, but it should be borne in mind that all tinctures or so-called extracts of vanilla are greatly improved by age. If allowed to stand for 3 or 6 months before using, the odor is vastly improved.

Commercial extracts of vanilla are sometimes not made from vanilla bean, but are simply hydro-alcoholic solutions of vanillin suitably colored and sweetened. Such practice can be readily detected as follows: If some of the extract be freed from alcohol by evaporation on a water-bath, made up to its original volume by addition of water and acidified with acetic acid, a reddish-brown precipitate of resin will form in the case of the tincture made from vanilla bean; absence of such resin would indicate an artificial extract. The filtrate from this resin, in a tincture made from the bean, should give a copious precipitate with basic lead acetate solution. If the extract consist partly of vanillin solution and partly of tincture of vanilla bean, the detection becomes more difficult. Adulteration of extract of vanilla with coumarin may be detected by the method given under VANILLINUM (which see).

Uses.—Tincture of vanilla is used solely as a flavoring agent.

TINCTURA VERATRI, *U. S., P. G.*—Tincture of Veratrum.

Tincture of American hellebore, E.; *Teinture de vératre*, F.; *Nieswurzeltinktur*, G.

NOTE.—The strength of this tincture has been reduced from 40 Gm. to 10 Gm. of veratrum in 100 Cc.—U. S.

Preparation.—Veratrum, in No. 60 powder, 100 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the veratrum with 40 Cc. of alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of veratrum, moisten 730 grains of veratrum, in No. 60 powder, with 5 fluidrachms of alcohol, and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

The French and German Pharmacopœias both direct the tincture to be made from white hellebore by maceration, the former using 100 Gm. of the drug for 500 Gm. of 80 per cent. alcohol, and the latter 1 part of drug for 10 parts of 68½ per cent. alcohol.

The present tincture of veratrum is only ¼ as strong as that of 1890, and, besides, may be made either from the green or white veratrum, since both varieties are now officially recognized under the title Veratrum. It is of a reddish-brown color, and has a bitter and acrid taste, and becomes opalescent and turbid when mixed with water. Each Cc. of the official tincture represents 0.10 Gm., or each fluidrachm about 5¾ grains, of the drug.

Norwood's Tincture of Veratrum Viride, a semi-proprietary preparation, which at one time was largely used by physicians, has been almost entirely replaced by the official fluidextract of the drug. It was supposed to be a saturated tincture, and was prepared from the fresh root of veratrum viride by maceration with alcohol, in the proportion of 240 grains of drug for every fluidounce of alcohol. It can be safely asserted that Norwood's tincture was decidedly inferior to the present fluidextract, and that its strength was perhaps rarely uniform.

Uses.—The present tincture being only one-fourth the strength of the U. S. P., 1890, it is given in 4 times the quantity of the former tincture. The dose is from 10 to 30 minims (0.60–2 Cc.).

TINCTURA ZINGIBERIS, *U. S., Br., P. G.*—Tincture of Ginger.

Teinture de gingembre, Fr.; *Ingwertinktur*, G.

Preparation.—Ginger, in No. 50 powder, 200 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the ginger with 60 Cc. of alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for 6 hours; then pack it firmly and pour on enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and,

having closely covered the percolater, macerate for 24 hours. Then allow the percolation to proceed slowly, pouring on sufficient alcohol to obtain 1000 Cc. of tincture.—U. S.

To make 1 pint of tincture of ginger, moisten 3 avoirdupois ounces and 148 grains of the powdered drug with 1 fluidounce of alcohol, and proceed as directed above, allowing percolation to continue until 16 fluidounces of tincture have been obtained.

Other pharmacopœias direct: Ginger, 2 ounces; alcohol, sufficient to make 1 imperial pint of tincture by percolation.—Br. Ginger, 100 Gm.; alcohol (80 per cent.), 500 Gm. —Fr. Cod. Ginger, 1 part; alcohol (68½ per cent.), 5 parts.—P. G.

Tincture of ginger, also familiarly known as essence of ginger, if made with strong alcohol as officially directed, has a brownish yellow or reddish color, and the aromatic odor and hot taste of the root. When added to water a milky mixture results, owing to precipitation of the resin. If the tincture be made with diluted alcohol a darker but somewhat turbid tincture will be obtained.

Uses.—Tincture of ginger is employed as a carminative for the relief of abdominal pain due to flatus, and as an addition to tonic and purgative mixtures to enhance their efficiency. Locally, it is mildly irritant. The dose is from 20 to 60 minims (1.30–4 Cc.).

TINCTURÆ HERBARUM RECENTIUM, *U. S.*—Tinctures of Fresh Herbs.

Alcoolaturæ, Fr. Cod.; *Alcoolatures*, Fr.; *Tinkturen von frischen Pflanzen*, G.

Tinctures made from fresh herbs were to some extent prepared more than two hundred years ago, but were more prominently introduced by Hahnemann, and are extensively employed in homœopathic practice. They have attracted more or less attention in Europe since about 1817, when Schrader (*Buchner's Repertorium*, iii. 20) made a number of investigations, and recommended such tinctures prepared from the fresh juice and twice its weight of alcohol. A similar method was subsequently advocated by Béral and by Deschamps, while Soubeiran suggested the use of the fresh plants and their maceration with strong alcohol in definite proportions. This method was adopted in the French Codex of 1866, and has been retained in that of 1884. Tinctures made from fresh herbs have been retained in the new U. S. Pharmacopœia, which, however, gives only a general formula.

Preparation.—"These tinctures, when not otherwise directed, are to be prepared by the following formula: Take of the fresh herb, bruised or crushed, 500 Gm.; alcohol, 1000 Cc. Macerate the herb with the alcohol for 14 days; then express the liquid and filter."—U. S.

This is essentially the formula for preparing the third class of tinctures of the Homœopathic Pharmacopœia. The French Codex directs equal parts of the fresh drug and of 90 per cent. alcohol, the maceration to be continued for 10 days; in this manner alcoholatures are prepared from aconite leaves and root, arnica flowers, belladonna leaves and root, bryony, colchicum flowers and root, conium leaves, digitalis leaves, drosera (entire plant), eucalyptus leaves, hyoscyamus leaves, pulsatilla (flowering herb), spilanthes flowers, and stramonium leaves.

It is evident that these preparations must vary in strength at least to the same extent as juices (see p. 1471), and that they are of doubtful utility, except perhaps for such drugs which owe their virtues to very volatile uncombined principles.

TRAGACANTHA, *U. S., Br., P. G.*—Tragacanth.

Gummi tragacanthæ or *Astragalorum.*—*Traganth*, E.; *Gomme Adragante*, Fr.; *Goma Adraganta*, G.; *Draganta*, It.; *Alcatira, Alquitira*, Port.; *Goma Tragacanta, Alquitira*, Sp.

A gummy exudation from *Astragalus gummifer* Labill. and from other species of *Astragalus* (Fam. *Leguminosæ*).

Tragacanth is official in all pharmacopœias, a number of species being variously named by them.

Origin and Collection.—The species of Astragalus yielding this product are members of the subgenus *Tragacantha*, the petioles united with the permanent stipules, which become thorny, and which subgenus properly should be regarded as forming a distinct

genus. They are low shrubs, indigenous to a portion of the territory lying between eastern Persia and Greece. Boissier names 9 or 10 species.

The secretion of tragacanth is due to a transformation of the cell-walls, with their incrusting layers, of the pith and medullary rays contained in the stem and older branches, as was first observed by Hugo von Mohl (1857), whose observations were corroborated by Wigand (1861). The altered tissue is confined in the plant between the wood-wedges with considerable tension, and oozes out with some force on breaking a branch or making an incision. Tragacanth exudes spontaneously either from fissures or from punctures and longitudinal incisions made into the stem and older branches. From such incisions flake tragacanth is obtained, while the spontaneously exuding gum often forms irregularly globular or somewhat conical pieces. The rapidity with which the gum exudes chiefly determines the shape in which it ultimately hardens, and the time which elapses before it is sufficiently hard for collection influences the color of the product, which is white if congealed rapidly, and more or less yellowish and brown if hardened slowly. Tragacanth enters commerce from the ports of Asia Minor and from the Persian Gulf.

Fig. 450.

Tragacanth (Nat.).

Properties.—Tragacanth consists of different layers, either laid one upon another and spirally twisted, or confluent into tear-like masses, or extended into curved, narrow, or broad bands, varying in width between 6 and 25 Mm. ($\frac{1}{4}$ and 1 In.), and sometimes 10 to 13 Cm. (4–5 In.) long. These bands are rarely made up of a single layer, but usually are marked with several parallel ridges, indicating the various strata, which are united into broader and thicker laminæ. This form of tragacanth is known as flake tragacanth or leaf gum, and is the more valuable the whiter and more translucent it is. Smyrna tragacanth is mostly in rather broad and thick flakes, which are yellowish or of a brownish tint, and often prominently ridged. Thin, ribbon-like, and white flakes are produced in Kurdistan and Persia, but are sometimes distinguished in commerce as Syrian tragacanth. Another variety is vermiform tragacanth, also called vermicelli. It consists of very narrow, variously coiled, and contorted string-like pieces, the different coils of which are most frequently confluent. Common tragacanth, or sorts, in Europe known as traganton, is the product obtained by spontaneous exudation, forming subglobular, conical, or variously shaped tear-like pieces, with the surface rounded and more or less irregular, and usually of a brownish or brown color, and rather waxy in appearance; but it shows the stratification described above, and, like the white and thin bands, encloses starch.

Tragacanth is hard, tough, difficult to powder, inodorous, and tasteless, insoluble in alcohol and ether, and forms with 50 parts of water a thick, jelly-like mucilage. When diffused in a much larger quantity of water it forms a ropy liquid which may be passed through a filter, leaving behind an insoluble residue, which in contact with iodine acquires a blue color from the presence of starch. The mucilage acquires a yellow color on the addition of caustic soda, and the solution of tragacanth yields clear mixtures with borax, ferric chloride, and sodium silicate, is precipitated by alcohol, thickened by cold lead acetate and subacetate, and precipitated by these salts on heating (Flückiger).

Composition.—The soluble gum is not identical with arabin, though its solution is precipitated by alcohol and ammonium oxalate. The insoluble gum is known as bassorin, traganthin, adraganthin. It is soluble in hydrochloric acid and in ammonia, and is stated to have the composition $C_{12}H_{10}O_{10}$. By drying, tragacanth loses about 15 per cent. of moisture; the ash contains over half its weight of calcium carbonate.

Action and Uses.—Tragacanth is demulcent, and was formerly employed to allay the irritation and cough of bronchitis and sore throat. Its medicinal and pharmaceutical properties resemble those of acacia, but on account of its difficult solubility it is less eligible than gum arabic in most instances.

Allied Gums.—A large number of gums of more or less commercial importance have been described elsewhere, especially under Acacia. The following are of special interest in connection with Tragacanth.

Bassora or *Kutera Gum* is a Persian product of unknown derivation. It may be closely related to, or even identical with, the article known as *Persian Sarcocolla* (see below). It is met with in yellowish or brownish, semi-transparent, and tasteless masses, which swell considerably with water. It is used in Smyrna for adulterating the cheaper varieties of tragacanth, and is then usually broken into smaller pieces of about the same size as the tragacanth. Such broken pieces are angular, and are said to be sometimes artificially whitened with white lead. This fraud may be readily detected by treating the gum with cold dilute nitric acid.

Sarcocolla (*Fleischleimgummi, Fischleimgummi,* G.; *Sarcocolle,* Fr.) is the gummy exudation of *Penœa Sarcocolla* L. and *P. mucronata* L. (Fam. *Penœaceœ*), small shrubs of Central and South Africa. Dymock, however, believed the Persian variety to be derived from a species of *Astragalus*. Sarcocolla occurs in small, roundish, somewhat spongy, and friable grains which are sometimes agglutinated to larger masses, often mixed with fine hairs, and have a yellowish, reddish, or brownish color. It is inodorous, has an insipid, sweetish, afterward somewhat acrid and bitter taste, resembling that of licorice-root; is soluble in water, almost completely soluble in alcohol, except the impurities, and when heated burns and gives off the odor of burning sugar. On treating sarcocolla with ether, Pelletier (1834) separated a resin; the undissolved residue yielded to alcohol sarcocollin, and left gummy matter behind. Sarcocollin is uncrystallizable, soluble in alcohol and water, possesses a bitter-sweet taste, and when oxidized with nitric acid yields oxalic acid. Its composition is said to be $C_{13}H_{23}O_6$. The name of this substance, which means a "joiner" or "healer of the flesh," it has borne since an early period in the history of medicine. It was held in great repute for agglutinating wounds and curing defluxions of the eyes, and was applied to joints affected with chronic inflammation. It was reputed to be a depilatory, was used with honey to check otorrhœa, and was applied with nitre as a discutient of scrofulous glands.

TRIMETHYLAMINA.—Trimethylamine.

Triméthylamine, Fr.; *Trimethylamin,* G.

Formula, $N(CH_3)_3$. Molecular weight, 58.66.

Origin and Preparation.—This compound, frequently incorrectly called *propylamine*, with which it is isomeric, has been obtained from ergot (*secaline*), from the leaves of beta vulgaris and chenopodium vulvaria, from the flowers of arnica montana, pyrus communis, sorbus aucuparia, and cratægus oxyacantha, and from codliver oil, bone oil, and guano. It is also produced on heating codeine with potassium hydroxide, but may be economically obtained from herring-pickle, which contains this alkaloid in considerable quantity and owes to it its peculiar odor. A mixture of herring-pickle and lime is subjected to distillation, the alkaline distillate is neutralized with hydrochloric acid and evaporated, and the saline residue is treated with absolute alcohol, which leaves ammonium chloride undissolved. The alcoholic solution is evaporated, the residue redissolved in a little water, and again carefully distilled with lime. If the vapors are first passed through an empty bottle, before they are condensed by means of ice or conducted into water, several less volatile alkaloids are separated in the bottle. Large quantities of trimethylamine are now obtained from the residues left in the preparation of sugar from beets.

Properties.—In its pure state trimethylamine is a colorless, thin, strongly alkaline liquid which at 0° C. (32° F.) has a specific gravity of 0.673, and boils at 9.8° C. (49.6° F.). At ordinary temperatures it is a colorless inflammable gas. It has a strong ammoniacal odor modified by the peculiar odor of herring-pickle. It is readily soluble in water and alcohol. An impure aqueous solution of trimethylamine has been sold as *propylamine*. It combines with mineral acids to form salts which are soluble in alcohol. Its acid aqueous solutions yield precipitates with potassium ferrocyanide, iodine in potassium iodide, tannic acid, potassium mercuric iodide, and phosphomolybdic acid.

Trimethylamine chloroplatinate is soluble in alcohol and water, crystallizes in well-defined orange-colored octahedrons, and contains 37.21 per cent. of platinum. More characteristic, particularly in the presence of methylamine and allied bases, is the double salt with gold, which is very sparingly soluble in cold water, and has the composition $N(CH_3)_3HCl.AuCl_3$ (Hesse, 1857, 1883).

Trimethylamine Hydrochloride, $N(CH_3)_3HCl$, is obtained on neutralizing the alkaloid with hydrochloric acid and evaporating. It crystallizes in white or colorless prisms, is nearly inodorous, has a saline pungent taste, is very deliquescent on exposure, and dissolves freely in water and alcohol.

Action and Uses.—Trimethylamine and its chloride possess no properties which commend their employment in modern medicine. Upon the skin and mucous membranes trimethylamine itself has a decidedly irritant effect, resembling that of ammonia. In full medicinal doses it and its salt are likely to excite gastric pain and depress the heart and lower body temperature. They are claimed by some to decrease the excretion of urea in all cases, but that this effect is constant is denied by others. In the treatment of acute rheumatic fever and gout they were highly recommended 30 or 40 years ago, especially by Russian and French physicians. It was asserted that under the influence of these drugs the pain rapidly diminished, the swelling of the joints subsided, the temperature fell, and the duration of the disease was considerably shortened. Such beneficial results were not obtained from their employment by English and American physicians. The dose of trimethylamine is from 2 to 8 minims (0.10–0.50 Cc.) every 3 or 4 hours. Of the chloride, 2 to 5 grains (0.12–0.30 Gm.) may be given.

Allied Compounds.—AMYLAMINE, $NH_2C_5H_{11}$, is a colorless liquid, having a penetrating ammoniacal odor, and the density 0.7503 at 18° C. and boiling at 95° C. (203° F.). The hydrochloride crystallizes in octahedrons, is freely soluble in water and alcohol, and is insoluble in ether.

PROPYLAMINE, $NH_2C_3H_7$, is a colorless, strongly refracting, inflammable liquid of an ammoniacal odor, boiling at 50° C. (122° F.), and yielding with platinic chloride a double salt, which crystallizes in orange-yellow clinorhombic plates.

METHYLAMINE, NH_2CH_3, and DIMETHYLAMINE, $NH(CH_3)_2$, are colorless inflammable gases of an ammoniacal odor, very soluble in water, and condensing to colorless liquids, the former at —18° C. (0.4° F.), the latter below 8° C. (46.4° F.).

BILINEURINE, CHOLINE, $C_5H_{15}NO_2$, is obtained by boiling bile with caustic baryta, and in a similar manner from brain, yolk of egg (see VITELLUS), and mustard-seed (*sinkaline*). It is present also in cotton-seed, fenugreek, fly agaric, herring-pickle; is formed in the human corpse in the beginning of decomposition, and has also been prepared synthetically. It is a colorless, syrupy, non-volatile liquid of a strong alkaline reaction, very hygroscopic, combining readily with carbon dioxide, and soluble in alcohol or water in all proportions; on heating it gives off trimethylamine, and on boiling its aqueous solution the same alkaloid is given off and ethyleneglycol produced. On treating its hydroiodide with silver oxide, the anhydrous base, $C_5H_{13}NO$, is separated. By careful oxidation *betaine*, $C_5H_{11}NO_2$, is produced.

TRITICUM, *U. S.*—Triticum, Couch-grass.

Rhizoma (*Radix*) *graminis.*—*Quick-grass, Scotch-grass, Twitch-grass, Witch-grass, Quickens, Quitch,* E.; *Chiendent officinal, Petit chiendent,* Fr. Cod.; *Queckenwurzel, Grasswurzel,* G.; *Grama,* Sp.; *Grama Franceza,* Port.; *Gramigna,* It.

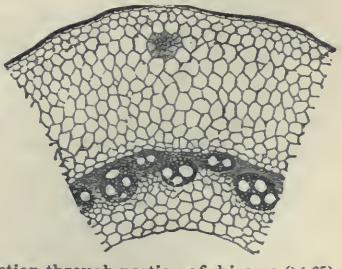
The dried rhizome of *Agropyron repens* (L.) Beauv. (*Triticum r.* L.—Fam. *Gramineæ*), collected in the spring and deprived of its roots.

Origin.—A tall, perennial, weedy grass, growing about buildings and troublesome in cultivated grounds, native of Europe and Asia, and widely naturalized in North

FIG. 451.

Triticum: rhizome; transverse section (× 3).

FIG. 452.

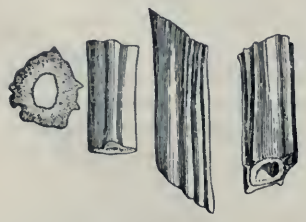


Section through portion of rhizome (× 65).

America. The compressed spikes somewhat resemble those of wheat, the spikelets being 4- to 8-flowered, the glumes mostly shortened or acute. The plant derived its names "Dog-grass" and "Couch-grass" from the fondness of dogs for lying in it; of quick-grass, from the rapidity with which its long, slender rhizomes extend its growth. The drug is almost wholly collected in central Europe.

Description.—About 2 Mm. ($\frac{1}{12}$ In.) thick, mostly cut into sections about 5 to 10 Mm. ($\frac{1}{5}$ to $\frac{2}{5}$ In.) long, pale straw colored, smooth and slightly shining, wrinkled, hollow, inodorous, gummy when chewed, and of a sweetish taste. The transverse section shows the central cavity surrounded by a narrow layer of delicate parenchyma, projecting somewhat into the equally narrow circle of fibro-vascular bundles, which is separated by the nucleus-sheath from the broad outer layer of parenchyma, containing about six or eight isolated, distant fibro-vascular bundles in a loose circle.

Fig. 453.



Commercial triticum (× 4).

Constituents.—The generally accepted analysis is that of Ludwig and Muller (1872): Dextrose and levulose 2.5–3.3 per cent., a dextrorotatory sugar (different from cane-sugar), triticin, acid malates, 11 per cent. of nitrogenous gummy matter (which forms an insoluble compound with acetate and subacetate of lead), and 4.5 per cent. of ash, containing much silica. Pope (1894) obtained inosit. Mannit, formerly thought to be present, has not been obtained by recent analysts, though it is said to sometimes form when fermentation occurs. Triticin is an amorphous, very hygroscopic and deliquescent white powder, without odor or taste, soluble in water and dilute alcohol, and insoluble in ether and absolute alcohol. It is oxidized to oxalic acid by nitric acid, and yields levulose on hydrolysis with water or strong alcohol.

Pharmaceutical Preparation.—Fluidextract of Triticum, U. S. P.

Action and Uses.—Triticum possesses only feeble medicinal qualities. In decoction or infusion it was formerly largely used as a domestic remedy in fevers, jaundice, bronchitis, gout, and a host of other diseases. Its sole employment to-day is as a gentle, soothing diuretic in acute inflammations of the urinary passages. It is best administered in decoction in any quantity. The fluidextract may be used in the dose of 1 to 2 drachms (4–8 Cc.), well diluted.

Allied Drugs.—The rhizome of a number of other grasses, notably of *Imperata Braziliensis* Trin., *T. exaltata* Brongn., *Capriola Dactylon* (L.) Kuntze (*Panicum D. L.*; *Cynodon D.* Pers.), the *Scotch* or *Bermuda Grass*, and one called "Grama Dulce," in the Andes, are similarly used. The grain of the sorghum, both the sugar and the broom-corn varieties, is commonly so used by our Southern negroes, and has been found by Dr. Garnett to have the properties in a mild degree. It is about 3 or 4 Mm. ($\frac{1}{8}$ to $\frac{1}{6}$ In.) long, broadly oval, obtuse, lightly flattened, enclosed in the glossy, somewhat granular palets, of varying shades, of yellow, red, or purple brown, internally white and mealy, inodorous, and of a farinaceous and sweetish taste. The seeds of *Coix Lachryma-Jobi* L. (*Lithagrostis L.* Gaertn.), the Job's tears, often used as beads for rosaries, are reputed diuretic and lithontriptic, though the idea appears to be rather imaginative, deduced apparently from their popular name. The Asiatic species, *C. gigantea* Roxb., called *Y-dzi* and *Bobo*, used as a food, are also reputed diuretic. Their meal is supposed to be useful in purifying water for drinking purposes when thrown upon its surface. They are rather rich in fat.

The seeds of *Phalaris Canariensis* L., the well-known canary seed, *Kanariensamen* (G.), *Aepiste* (Fr., Sp.), are rather nutritive, and have been used as food by man, as well as for birds.

TRITURATIONES, *U. S.*—Triturations.

Triturations, Fr.; *Triturationen*, G.

This term has been used in homœopathic pharmacy in the same sense in which it has been adopted by the U. S. Pharmacopœia—namely, for powders prepared by trituration of a medicinal substance with a definite quantity of milk-sugar. In homœopathy this is done with a view of developing the medicinal power, and two proportions are used, termed the centesimal and the decimal scales; 1 part of the substance being triturated with 99 parts or with 9 parts of the milk-sugar gradually added.

Preparation.—The directions for preparing these powders are very similar to those followed in homœopathic dispensing, excepting that the length of time for mixing and triturating has been omitted.

"Triturations are to be prepared by the following formula: Take of the substance 10 Gm.; sugar of milk, in moderately fine powder, 90 Gm.; to make 100 Gm. Weigh the substance and sugar of milk separately; then place the substance, previously reduced, if necessary, to a moderately fine powder, in a mortar; add about an equal bulk of sugar of milk, mix well by means of a spatula, and triturate them thoroughly together. Add

fresh portions of the sugar of milk from time to time until the whole is added, and continue the trituration, after each addition, until the substance is intimately mixed with the sugar of milk, and reduced to fine powder."—U. S.

Uses.—Triturations play quite an important part in the practice of pharmacy, and will often be found very convenient at the dispensing counter when small fractions of potent drugs are needed in prescriptions. Thus, if 0.100 Gm. of the drug be thoroughly mixed by trituration with 0.900 Gm. of milk-sugar, every 0.010 Gm. of the mixture will represent 1 milligramme of the drug, and therefore any given multiple of 0.010 Gm. may be used to obtain the corresponding number of milligrammes. Likewise, if $\frac{1}{2}$ grain of the drug be mixed with 4½ grains of milk-sugar, or 1 grain with 9 grains, each grain of the mixture will represent $\frac{1}{10}$ grain of the drug; or if 1 grain of the drug be mixed with 47 grains of milk-sugar, 1 grain of the mixture will be equal to $\frac{1}{48}$ grain of the drug, 1½ grains = $\frac{1}{32}$ grain, 2 grains = $\frac{1}{24}$ grain, 3 grains = $\frac{1}{16}$ grain, 4 grains = $\frac{1}{12}$ grain, 6 grains = $\frac{1}{8}$ grain, 8 grains = $\frac{1}{6}$ grain, 12 grains = $\frac{1}{4}$ grain, 16 grains = $\frac{1}{3}$ grain, and 24 grains = $\frac{1}{2}$ grain.

TRITURATIO ELATERINI, *U. S.*—Trituration of Elaterin.

Trituration d'élatérine, Fr.; *Elaterintrituration*, G.

Preparation.—Elaterin, 10 parts; sugar of milk, 90 parts; to make 100 parts. Mix them thoroughly by trituration.—U. S.

Uses.—The dose of this preparation is from ¼ to 1 grain (0.015–0.06 Gm.).

TROCHISCI, *U. S., Br.*—Troches.

Tablettes, Pastilles, Fr. Cod.; *Pastilli, Rotulæ*, P. G.—*Lozenges*, E.; *Tablettes*, Fr.; *Pastillen, Plätzchen*, G.

Troches or lozenges are solid, flattened masses of round, oval, or other desirable shape, not intended for mastication, but to be dissolved slowly in the mouth, therefore not adapted for medicines which are expected to undergo disintegration in the stomach prior to any therapeutic action. In one or two cases the cylindrical form is preferred, as for the well-known licorice lozenges. The remedial action of lozenges is generally designed to be purely local, either as an expectorant, demulcent, stimulant, sedative, astringent, or antiseptic.

The usual base or vehicle for lozenges is sugar (that known among confectioners as lozenge sugar being preferred), although powdered extract of licorice also is added at times, and, of late years, fruit paste, made from black or red currants, has come extensively into use for certain kinds of lozenges. Adhesiveness is obtained by the addition of tragacanth or acacia, and syrup or water (plain or aromatic) is used to supply the necessary moisture. All medicinal constituents, as well as the sugar or extract of licorice, should be in very fine powder to insure a smooth paste, and potent remedies, wherever possible, should be added either in the form of solution or triturated with a small quantity of sugar before being mixed with the other ingredients, so as to insure uniform distribution. Tragacanth is preferable to acacia for making a lozenge-mass, as the resulting paste is more tenacious; in both cases the mucilage is to be preferred to the powder with the subsequent addition of water, as in the latter case it is often difficult to avoid an excess of moisture, which retards subsequent drying.

The British Pharmacopœia (1898) admits acacia only as the adhesive agent for lozenges, and designates four distinct bases or vehicles of the following composition: *Simple basis*—Refined sugar, 17½ avoirdupois ounces; powdered acacia, 300 grains; mucilage of acacia, 1¼ fluidounces; distilled water, a sufficient quantity. *Fruit basis*—Refined sugar, 15½ avoirdupois ounces; powdered acacia, 300 grains; mucilage of acacia, 1¼ fluidounces; black-currant paste, 2 avoirdupois ounces; distilled water, a sufficient quantity. *Rose basis*—Refined sugar, 17½ avoirdupois ounces; powdered acacia, 300 grains; mucilage of acacia, 5 fluidrachms; rose water, a sufficient quantity. *Tolu basis*—Refined sugar, 17 avoirdupois ounces; powdered acacia, 300 grains; mucilage of acacia, 1¼ fluidounces; tincture of tolu, 3 fluidrachms; distilled water, a sufficient quantity; dissolve what salts of alkaloids may be ordered in 3 fluidrachms of distilled water, and mix this solution with the sugar. Instead of giving individual formulas for making the 17 varieties of lozenges recognized, a general formula, adjusted for 500 loz-

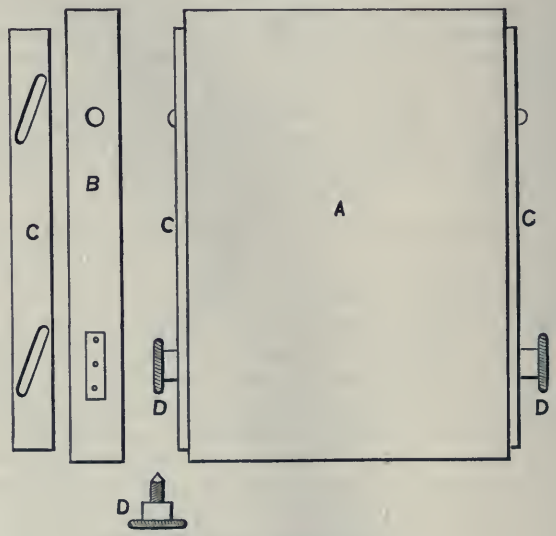
enges, is given under the head of each basis, as follows: 500 times the quantity of medicinal agent required for 1 lozenge is intimately mixed with the sugar and acacia, and a paste then made with the other ingredients, which is divided into 500 equal parts and dried at a moderate temperature.

Lozenge-masses are made after the manner of pill-masses, except that more adhesive material is used, and the paste is made somewhat softer. The proportion of powdered tragacanth necessary for a well-made plastic mass may vary from 1 to 3 per cent. of the total weight of the mixed powders (acacia about 3 or 4 times as much); and in making the mass the necessary water or syrup should be added cautiously, and the mixture well kneaded after each addition, so as to avoid too soft a condition, which readily occurs on account of the great solubility of the sugar. A good plan is to follow the suggestion of Hager, to reserve about $\frac{1}{5}$ of the powder, and when the remaining $\frac{4}{5}$ have been made into a plastic mass, quickly incorporate the reserve portion, which can be done without risk of the mass becoming dry and crumbly. For massing small quantities of material a Wedgewood mortar and pestle will be found quite convenient, while for large quantities hand- or steam-power machines, such as are used for pill-masses. are needed.

After a suitable mass has been made, it is transferred to a hardwood board or a stone slab, rolled out into either a flat sheet or a cylinder, and divided into the requisite number of parts. When cylindrical lozenges are to be made, the mass is rolled out without dusting and divided into pieces about $\frac{5}{8}$ of an inch in length, by means of a special cutter. In order to prevent the mass from adhering, the flat roller may be lightly rubbed with a very small quantity of oil of sweet almond. For flat lozenges the mass is conveniently rolled out into a sheet, the required thickness of which must be ascertained by experiment; this is done by dividing the weight of the whole mass by the number of lozenges to be made, then weighing off as many grains of the mass as correspond to the quotient obtained, and forming this into a lozenge by means of a punch or spatula. As every well-made lozenge-board is provided with guides and screws for regulating different thicknesses, no difficulty will be experienced in adjusting the side strips to the proper height, and then rolling out the mass by means of a cylindrical roller. To prevent adhesion of the mass, the board may be dusted with a little starch or a mixture of starch and sugar.

The lozenge-board designed by Wallace Procter is very useful and simple in construction, as shown in Fig. 454. A is a board of well-seasoned hard wood, 1½ inches

FIG. 454.



Procter's lozenge-board.

thick, 10 inches wide, and 14 inches long, planed perfectly flat, and both sides and ends made square and true. At each side, about 3 inches from one end, a plate is let in flush and tapped with a screw, as shown in B. On each side of the board a plate of brass, 1½ inches

wide, 14 inches long, and $\frac{3}{16}$ of an inch thick, is fitted. Each plate has two slots crossing it diagonally (see C) $\frac{3}{8}$ of an inch from each edge; these slots must have exactly the same slope, and the front slot should be ruled to divisions of $\frac{1}{32}$ of an inch. Through one slot of each plate a square-shouldered screw passes, and is screwed in until it presses the plate close to the side of the board, but still permits it to move easily; through the other slot in each plate passes a set-screw, which enters the screw-plate before mentioned. When the plates have been adjusted to a given height the set-screws are turned until they prevent motion of the plate.

The punches used for cutting lozenges are usually in the form of tapering cylinders, made of heavily tinned iron, and frequently provided with sharp cutters of hardened steel, the shape of which varies with the fancy of the operator; sometimes they are made with straight sides and fitted with a plunger, operated by a spring, for the ready expulsion of the lozenges. In large manufacturing establishments 10 or 12 cutters are frequently combined and operated as one, greatly expediting the work. Whenever it is desired to stamp lozenges with some special letter or design, this is done at the time of cutting them, the plunger being provided with the necessary die.

For a number of years lozenges have also been made by compression of the material in the form of a granular powder into lenticular-shaped disks by means of specially constructed apparatus operated by hand, steam, gas, or electric power. Such lozenges are more appropriately designated as compressed tablets, and vary from $\frac{3}{8}$ to $\frac{5}{8}$ of an inch in diameter.

Gelatin lozenges, variously medicated, have been in use for some time, more particularly in Europe. They are composed of a mixture of gelatin, glycerin, and water, holding the medicinal ingredients either in solution or simple admixture. The base is often termed glyco-gelatin, and is made by macerating gelatin with water on a water-bath, and then adding glycerin; two kinds, containing different proportions of gelatin and glycerin, are in use. A mixture of gelatin, 1 ounce; orange-flower water, 2½ ounces; and glycerin, 2½ ounces (by weight), yields the softer variety, which is very readily soluble in the mouth; whereas a mixture of gelatin, 5 ounces; orange-flower water, 6 ounces; and glycerin, 6 ounces (by weight), evaporated to 15 ounces, produces a much firmer mass, dissolving more slowly, but probably better adapted for stock lozenges in this latitude; in the latter case at least 12 hours' maceration should be given the gelatin and water before adding the glycerin and applying heat. Gelatin lozenges must always be made with the aid of heat, and the mass after thorough admixture with the medicinal ingredients, while still in a melted condition, is poured into suitable molds, where it rapidly congeals. A very convenient mold for a small number of the lozenges is found in the two side plates of the Konseal filling and closing apparatus mentioned on p. 1264. If either of these plates be laid upon a cold porcelain or glass plate, the mixture may be poured directly into the particular perforations selected, and when cold the lozenges are easily removed by being pushed through the perforations. The proper quantity of gelatin mass to use for any particular case is ascertained by filling the perforations with some of the melted plain mass, and when cold weighing the disk; by keeping a memorandum of the weight of such disks much annoyance and labor can be saved. Gelatin lozenges vary in weight from 5 to 15 grains (0.3–1.0 Gm.).

Gelatin lozenges, while admirably adapted for the exhibition of such substances as cocaine, boric acid, carbolic acid, etc., are unsuited for tannin, extract of rhatany, and other agents incompatible with gelatin.

Chocolate lozenges, also known as chocolate tablets and chocolate pastilles, or simply as chocolates, may be conveniently made at the dispensing-counter as follows: The medicinal ingredients are intimately mixed with powdered sugar previously flavored with vanilla, Ceylon cinnamon, peppermint, or other flavoring agent, and the mixture then added to three-fourths of its weight of chocolate, in mass or powder, contained in a mortar or porcelain dish. By means of water-bath heat a soft mass is obtained, which is thoroughly mixed, and when cool divided into the requisite number of parts on a lozenge-board or a pill-tile. Chocolate lozenges vary in weight from 5 to 15 grains (0.3–1 Gm.), and are not intended to be dissolved slowly in the mouth, but to be swallowed with or without previous mastication.

Lozenges intended for immediate use do not require much drying, but those intended for stock must be thoroughly dried before they are put away in glass containers, otherwise they are liable to soften and adhere, and may even become moldy. The drying

is best effected on perforated trays in a moderately warm room. To avoid cracking of the edges, which will sometimes occur when lozenges are dried, the addition of a small quantity of glycerin to the water used will be found advantageous, and does not interfere with proper desiccation.

The average weight of lozenges is between 10 and 20 grains, (0.650 and 1.30 Gm.), although in the fifteen working formulas of the Pharmacopœia the weight is found to vary between 6½ and 24 grains (0.42 and 1.59 Gm.).

TROCHISCI ACIDI BENZOICI.—Benzoic Acid Lozenges.

Trochiscus acidi benzoici.—Benzoic acid lozenge, Br.; *Tablettes de l'acide benzoique*, Fr.; *Benzoesäurepastillen*, G.

Preparation.—Benzoic acid, ½ grain or 0.0324 Gm. Mix with the fruit basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—This is a useful voice lozenge, 1 to be taken every 2 or 3 hours.

TROCHISCI ACIDI CARBOLICI.—Carbolic Acid Lozenges.

Trochiscus acidi carbolici.—Phenol lozenge, Br.; *Tablettes de l'acide phénique*, Fr.; *Phenolpastillen*, G.

Preparation.—Phenol, 1 grain or 0.0648 Gm. Mix with the tolu basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—These lozenges may be used as a mild sedative and antiseptic in inflammations of the mouth or throat. 1 every 2 or 3 hours.

TROCHISCI ACIDI TANNICI, *U. S.*—Troches of Tannic Acid.

Trochiscus acidi tannici.—Tannic acid lozenge, Br.; *Tablettes de tannin*, Fr.; *Tanninpastillen*, G.

Preparation.—Tannic acid, 6 Gm.; sugar, in fine powder, 65 Gm.; tragacanth, in fine powder, 2 Gm.; stronger orange-flower water, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then with orange-flower water form a mass, to be divided into 100 troches.—U. S.

To make 25 tannin lozenges use 25 grains of tannic acid, 250 grains of sugar, and 8 grains of powdered tragacanth.

Tannic acid, ½ grain or 0.0324 Gm. Mix with the fruit basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—Tannic acid troches are suitable to allay cough and irritation and huskiness of the voice due to relaxed states of the mouth, throat, and larynx.

TROCHISCI AMMONII CHLORIDI, *U. S.*—Troches of Ammonium Chloride.

Tablettes de sal ammoniac, Fr.; *Salmiakpastillen*, G.

Preparation.—Ammonium chloride, in fine powder, 10 Gm.; extract of glycyrrhiza, in fine powder, 20 Gm.; sugar, in fine powder, 40 Gm.; tragacanth, in fine powder, 2 Gm.; syrup of tolu, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then with syrup of tolu form a mass, to be divided into 100 troches.—U. S.

To make 25 ammonium chloride lozenges use 40 grains of ammonium chloride, 80 grains of extract of licorice, 160 grains of sugar, and 8 grains of powdered tragacanth.

Uses.—These troches are used to relieve subacute and chronic inflammations of the throat and lungs.

TROCHISCI BISMUTHI.—Bismuth Lozenges.

Trochiscus bismuthi compositus.—Compound bismuth lozenge, Br.; *Tablettes de sous-nitrate de bismuth*, Fr. Cod.; *Wismuthpastillen*, G.

Preparation.—Bismuth oxycarbonate, 2 grains or 0.1296 Gm.; heavy magnesium carbonate, 2 grains or 0.1296 Gm.; precipitated calcium carbonate, 4 grains or

0.2592 Gm. Mix with the rose basis to form a lozenge.—Br. (See general directions on page 1579.)

The corresponding lozenges of the French Codex contain 1.5 grains (0.10 Gm.) of bismuth subnitrate, but no magnesia or calcium carbonate.

Uses.—Bismuth troches may be used to correct acidity of the stomach and to relieve diarrhœa. 1 to 3 will usually be sufficient.

TROCHISCI CUBEBÆ, *U. S.*—Troches of Cubeb.

Pastilles de cubèbe, Fr.; *Kubebenpastillen*, G.

Preparation.—Oleoresin of cubeb, 2 Gm.; oil of sassafras, 1 Cc.; extract of glycyrrhiza, in fine powder, 25 Gm.; acacia, in fine powder, 12 Gm.; syrup of tolu, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then add the oleoresin and oil and incorporate them with the mixture. Lastly, with syrup of tolu form a mass, to be divided into 100 troches.—U. S.

To make 25 cubeb lozenges use 8 grains of oleoresin of cubebs, 6 drops of oil of sassafras, 100 grains of extract of licorice, and 48 grains of powdered acacia.

This is a modification of the formula for Spitta's lozenges, from which it differs essentially in the substitution of oleoresin for powdered cubebs. The lozenges are usually made of a cylindrical shape, and each contains about ½ grain of oleoresin of cubeb.

The present lozenges contain ½ as much oleoresin of cubeb as those of the 1890 Pharmacopœia.

Uses.—These troches are useful in subacute inflammations of the pharynx and larynx.

TROCHISCI EUCALYPTI.—Eucalyptus Lozenges.

Trochisci eucalypti gummi.—Eucalyptus gum lozenge, Br.; *Tablettes d'eucalypte*, Fr.; *Eucalyptuspastillen*, G.

Preparation.—Eucalyptus gum, 1 grain or 0.0648 Gm. Mix with the fruit basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—Troches of eucalyptus, popularly known as "red gum lozenges," are employed to allay the irritation and cough of pharyngitis and laryngitis.

TROCHISCI FERRI REDUCTI.—Reduced Iron Lozenges.

Trochiscus ferri reducti.—Reduced iron lozenge, Br.; *Tablettes de fer réduit par l'hydrogène, Pastilles chalybées*, Fr.; *Eisenpastillen*, G.

Preparation.—Reduced iron, 1 grain or 0.0648 Gm. Mix with the simple basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—This is an unnecessary preparation. The dose is 1 to 3 lozenges.

TROCHISCI GAMBIR, *U. S.*—Troches of Gambir.

Trochisci catechu, U. S., 1890.—*Trochiscus catechu, Catechu lozenge*, Br.; *Tablettes de cachou*, Fr. Cod.; *Katechupastillen*, G.

Preparation.—Gambir, in fine powder, 6 Gm.; sugar, in fine powder, 65 Gm.; tragacanth, in fine powder, 2 Gm.; strong orange-flower water, a sufficient quantity to make 100. Rub the powders together until they are thoroughly mixed; then, with stronger orange-flower water, form a mass, to be divided into 100 troches.—U. S.

Catechu, 1 grain or 0.0648 Gm. Mix with the simple basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—These troches are employed for the same purposes as troches of TANNIC ACID (which see).

TROCHISCI GLYCYRRHIZÆ ET OPII, *U. S.*—Troches of Glycyrrhiza and Opium.

Licorice and opium lozenges, E.; *Pastilles de réglisse opiacées*, Fr.; *Opiumpastillen*, G.

Preparation.—Extract of glycyrrhiza, in fine powder, 15 Gm.; powdered opium, 0.5 Gm.; acacia, in fine powder, 12 Gm.; sugar, in fine powder, 20 Gm.; oil of anise,

0.2 Cc. ; water sufficient to make 100 troches. Rub the powders together until they are thoroughly mixed ; then add the oil of anise (equivalent to about 4 drops), and incorporate it with the mixture. Lastly, with water form a mass, to be divided into 100 troches.—U. S.

To make 25 licorice-and-opium lozenges use 58 grains of extract of licorice, 2 grains of powdered opium, 48 grains of acacia, 78 grains of sugar, and 1 drop of oil of anise.

The lozenges contain about $\frac{1}{12}$ grain of powdered opium. They are much used under the name of *Wistar's cough lozenges*, and are prepared of a cylindrical shape.

Uses.—These troches are excellent to allay the cough of bronchitis and inflammation of the throat. If taken too often they will cause constipation. 1 every hour or two usually suffices.

TROCHISCI GUAIACI.—Troches of Guaiac.

Trochiscus guaiaci resinæ. — Guaiacum resin lozenge, Br. ; *Tablettes de résine de gayac*, Fr. ; *Guajakharzpastillen*, G.

Preparation.—Guaiacum resin, 3 grains or 0.1944 Gm. Mix with the fruit basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—This is a useful expectorant lozenge.

TROCHISCI IPECACUANHÆ.—Troches of Ipecac.

Trochiscus ipecacuanhæ.—Ipecacuanha lozenge, Br. ; *Tablettes d'ipecacuanha*, Fr. Cod. ; *Brechwurzelpastillen*, G.

Preparation.—Ipecacuanha root, in powder, ¼ grain or 0.0162 Gm. Mix with the fruit basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—Troches of ipecac are useful in laryngeal and bronchial inflammation before secretion has been established. If taken too often nausea will result.

TROCHISCI KRAMERIÆ, *U. S.*—Troches of Krameria.

Trochiscus krameriæ.—Krameria lozenge, Rhatany lozenge, Br. ; *Tablettes de ratanhia*, Fr. ; *Ratanhiapastillen*, G.

Preparation.—Extract of krameria, 6 Gm. ; sugar, in fine powder, 65 Gm. ; tragacanth, in fine powder, 2 Gm. ; orange-flower water, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed ; then with orange-flower water form a mass, to be divided into 100 troches.—U. S.

To make 25 rhatany lozenges use 25 grains of extract of rhatany, 250 grains of sugar, and 8 grains of powdered tragacanth.

Extract of krameria, 1 grain or 0.0648 Gm. Mix with the fruit basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—Krameria lozenges may be used, like those of tannic acid and gambir, to constringe the mucous membranes of the mouth, pharynx, and larynx, and to check diarrhœa.

TROCHISCI KRAMERIÆ ET COCAINÆ.—Troches of Krameria and Cocaine.

Trochiscus krameriæ et cocainæ.—Krameria and cocaine lozenge, Rhatany and cocaine lozenge, Br. ; *Tablettes de ratanhia et de cocaine*, Fr. ; *Ratanhia und Cocainpastillen*, G.

Preparation.—Extract of krameria, 1 grain or 0.0648 Gm. ; cocaine hydrochloride $\frac{1}{20}$ grain or 0.00324 Gm. Mix with the fruit basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—These lozenges are indicated when much pain accompanies inflammation of the throat.

TROCHISCI MENTHÆ PIPERITÆ.—Troches of Peppermint.

Tablettes de menthe, Fr. Cod.; *Rotulæ menthæ piperitæ*, P. G.—*Peppermint lozenge*, E.; *Pastilles de menthe anglais*, Fr.; *Pfefferminzplätzchen*, G.

Preparation.—Oil of peppermint, 10 Gm.; powdered sugar, 1000 Gm.; mucilage of acacia, 100 Gm. Prepare a lozenge paste in the usual manner, having previously triturated the oil of peppermint with $\frac{1}{10}$ of the total weight of sugar. Divide into lozenges weighing 1 Gm. each.—Fr. Cod.

The directions of the German Pharmacopœia are somewhat different, and correspond to those of the French Codex given for PASTILLES DE MENTHE À LA GOUTTE. Plain sugar lozenges are first made by mixing 1000 Gm. of sugar with 125 Gm. of hot water until a semifluid, non-transparent mass results, which is then allowed to fall upon an iron plate in such a manner that small semicircular masses result. When these have become firm 1 Gm. of oil of peppermint, dissolved in 2 Gm. of alcohol, is sprinkled over 200 Gm. of the lozenges, and the whole is then exposed to the air for a short time to allow the alcohol to evaporate.

Uses.—Peppermint lozenges are used as a pleasant confection and to relieve nausea and flatulence.

TROCHISCI MORPHINÆ.—Troches of Morphine.

Trochiscus morphinæ.—Morphine lozenge, Br.; *Tablettes de morphine*, Fr.; *Morphinpastillen*, G.

Preparation.—Morphine hydrochloride, $\frac{1}{360}$ grain or 0.0018 Gm. Mix with the tolu basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—Each lozenge contains $\frac{1}{360}$ of a grain of morphine hydrochlorids. They are used chiefly to relieve the cough of laryngeal and bronchial irritation.

TROCHISCI MORPHINÆ ET IPECACUANHÆ.—Troches of Morphine and Ipecac.

Trochiscus morphinæ et ipecacuanhæ.—Morphine and ipecacuanhæ lozenge, Br.; *Tablettes de morphine et d'ipecacuanha*, Fr.; *Morphin und Brechwurzelpastillen*, G.

Preparation.—Morphine hydrochloride, $\frac{1}{360}$ grain or 0.0018 Gm.; ipecacuanha root, in powder, $\frac{1}{12}$ grain or 0.0054 Gm. Mix with the tolu basis to form a lozenge.—Br. (See general directions on page 1579.)

Uses.—These troches are used to allay cough and promote secretion in the early stage of bronchitis.

TROCHISCI POTASSII CHLORATIS, *U. S.*—Troches of Potassium Chlorate.

Trochiscus potassii chloratis.—Potassium chlorate lozenge, Br.; *Tablettes de chlorate de potasse*, Fr. Cod.; *Kaliumchloratpastillen*, G.

Preparation.—Potassium chlorate, in fine powder, 15 Gm.; sugar, in fine powder, 60 Gm.; tragacanth, in fine powder, 3 Gm. Mix the sugar with the tragacanth by trituration in a mortar; then transfer the mixture to a sheet of paper, and by means of a bone spatula mix with it the potassium chlorate, being careful to avoid trituration and pressure, to prevent the mixture from igniting or exploding. Lastly, with water form a mass, to be divided into 100 troches.—U. S.

To make 25 potassium chlorate lozenges use 58 grains of finely powdered potassium chlorate, 233 grains of sugar, and 12½ grains of tragacanth.

Potassium chlorate, 3 grains or 0.1944 Gm. Mix with the rose basis to form a lozenge.—Br. (See general directions on page 1579.)

The corresponding lozenges of the French Codex contain 0.10 Gm. (1½ grains) of potassium chlorate.

Uses.—These lozenges are extensively employed in the treatment of aphthous stomatitis and sore throat.

TROCHISCI SANTONINI, *U. S.*—Troches of Santonin.

Trochiscus santonini.—Santonin lozenge, Br.; *Tablettes de santonine*, Fr.; *Pastilli santonini*, P. G.; *Santoninpastillen, Santoninzeltchen*, G.

Preparation.—Santonin, in fine powder, 3 Gm.; sugar, in fine powder, 110 Gm.; tragacanth, in fine powder, 3 Gm.; stronger orange-flower water a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then with stronger orange-flower water form a mass, to be divided into 100 troches. Santonin troches should be kept in dark, amber-colored bottles.

To make 25 santonin lozenges use 12 grains of santonin, 425 grains of sugar, and 12 grains of tragacanth.

Santonin, 1 grain or 0.0648 Gm. Mix with the simple basis to form a lozenge.—Br. (See general directions on page 1579.)

The official santonin lozenges of the U. S. contain about ½ grain of santonin, while those of the Br. contain 1 grain, and those of the P. G. nearly ½ grain (0.025 Gm., or $\frac{5}{13}$ grain).

Uses.—This is a very pleasant form in which to administer santonin. The dose is from 1 to 4 troches.

TROCHISCI SODII BICARBONATIS, *U. S.*—Troches of Sodium Bicarbonate.

Trochiscus sodii bicarbonatis.—Sodium bicarbonate lozenge, Br.; *Tablettes de bicarbonate de soude*, Fr. Cod.; *Pastilles de Vichy*, Fr.; *Natriumbicarbonatpastillen, Natronpastillen*, G.

Preparation.—Sodium bicarbonate, 18 Gm.; sugar, in fine powder, 54 Gm.; nutmeg, in fine powder, 1 Gm.; mucilage of tragacanth, a sufficient quantity to make 100 troches. Triturate the nutmeg with the sugar, gradually added, until they are reduced to a fine powder, and mix this intimately with the sodium bicarbonate; then, with the mucilage of tragacanth, form a mass, to be divided into 100 lozenges.—U. S.

To make 25 sodium bicarbonate lozenges use 68 grains of sodium bicarbonate, 216 grains of sugar, and 4 grains of nutmeg.

Sodium bicarbonate, 3 grains or 0.1944 Gm. Mix with the rose basis to form a lozenge.—Br. (See general directions on page 1579.)

The corresponding lozenges of the French Codex contain nearly ½ grain (0.025 Gm.) or $\frac{5}{13}$ grain of sodium bicarbonate.

Uses.—Troches of sodium bicarbonate are useful to correct acidity of the stomach and eructations.

TROCHISCI SULPHURIS.—Troches of Sulphur.

Trochiscus sulphuris.—Sulphur lozenge, Br.; *Tablettes de soufre*, Fr. Cod.; *Schwefelpastillen*, G.

Preparation.—Precipitated sulphur, 2500 grains; acid potassium tartrate, in powder, 500 grains; refined sugar, in powder, 4000 grains; acacia, in powder, 500 grains; tincture of orange, 500 minims; mucilage of acacia, 500 minims. Mix the tincture of orange with the powders, add the mucilage of acacia to form a suitable mass. Divide into 500 lozenges. Dry them in a hot-air chamber at a moderate temperature.—Br.

The corresponding lozenges of the French Codex contain 1½ grains (0.10 Gm.) of sulphur each, but no potassium bitartrate, and are flavored with orange-flower water, while the Br. lozenges contain 5 grains of sulphur each.

Uses.—Each lozenge contains 5 grains (0.30 Gm.) of sulphur. Dose, 1 to 6 lozenges.

TUBERCULIN.

Tuberculin is a glycerin extract of the soluble substances produced by the *Bacillus tuberculosis* when grown in 5 per cent. glycerin-beef bouillon.

R. Koch, 1882, showed that tuberculosis was a disease produced by a bacillus, which he named *Bacillus tuberculosis*. The same investigator several years later announced the discovery of a product derived from cultures of tubercle bacilli, which, when injected in minute, gradually increasing doses, produced curative action in patients suffering from

consumption, lupus, and other diseases produced by the germ. Extensive experiments in nearly all countries of the world showed that the application of the remedy was attended with considerable danger and but little benefit to the patient. While tuberculin did not prove a success as a curative agent, it was soon discovered that it produced a characteristic febrile reaction in tubercular patients which did not occur in those not infected with the germ. Likewise, it was found that the reaction was constant for the lower animals, especially cattle, and soon it came to be extensively used for the purpose of detecting tuberculosis in milch cows, being employed almost exclusively for this purpose at the present time.

Various methods have been employed for producing tuberculin, but the following is the one generally employed: Cultures of *Bacillus tuberculosis* are grown in 5 per cent. glycerin-beef bouillon (see ANTITOXINS), kept at body temperature, the growth being very slow and taking place mainly on the surface. After several months the cultures are removed from the incubator, examined microscopically, concentrated to one-tenth their volume by heat, and filtered. The resulting dark-brown syrupy fluid constitutes the tuberculin generally found upon the market. This is sometimes called "crude tuberculin." A purified product may be obtained by precipitating the crude product with 94 per cent. alcohol.

Uses.—Occasionally tuberculin is employed for diagnosis, and very rarely for the treatment of tuberculosis in human beings, being diluted sufficiently with sterile normal saline solution, so that a dose of 0.5 milligram or more is contained in about 1 Cc. of fluid. Tuberculin is employed mainly for the purpose of diagnosing tuberculosis in cattle in doses of 0.25 or more of the crude product diluted to a 10 per cent. solution with 0.5 per cent. carbolic acid, or sterilized normal saline solution. The temperature of the animals is taken before the tuberculin is injected, and repeatedly after injection. A rise in temperature of more than 1½ degrees F. is to be taken as evidence of tuberculosis.

Tuberculin is a fairly stable product, but should not be exposed to light. The value of tuberculin in aiding in the diagnosis of obscure tuberculosis in human beings is still *sub judice*. Some practitioners believe its use to be most valuable, while others believe that reaction sometimes takes place in non-tubercular patients, and that in some cases its use is followed by symptoms too severe to justify its employment.

TUSSILAGO.—Coltsfoot.

Horse-, Ass-, Foal-, or *Bull's-foot, Horse-hoof, Coughwort, Clay-weed, British Tobacco, Dove-dock,* etc., E.; *Huflattig, Rosshuf,* G.; *Tussilage, Pas d'ane,* Fr.; *Tusilago una de Caballo,* Sp.

The dried plant *Tussilago Farfara* L. (Fam. *Compositæ*). The leaves are used separately as *Folia farfaræ* or *tussilaginis,* and the rhizomes as *Radix* or *Rhizoma farfaræ* or *tussilaginis.*

The drug is official in none of the leading pharmacopœias, but it is very extensively used, especially in domestic practice.

Origin and Description.—The plant is a perennial, somewhat succulent, white-floccose herb, spreading by long fleshy rhizomes, which are usually deeply buried in clay or sand, especially in moist places. It is native of Europe and northern Asia, and is somewhat naturalized in northeastern North America. The rhizome is creeping, 30 to 45 Cm. (12–18 In.) long, branching, about 3 Mm. (⅛ In.) thick, with joints about 5 Cm. (2 In.) long, annulate on the nodes, and of a grayish-white or pale-brownish color. It is fragile when dry, has a thick bark, with whitish section, yellowish porous wood-wedges, and a prominent pith, is inodorous, and has a mucilaginous, bitterish, and astringent taste. The leaves appear after the flowers, and are radical, long-petiolate, about 10 Cm. (4 In.) long and broad, roundish heart-shaped, angular-toothed, dark green and smooth above, and white-tomentose beneath. They are rather fleshy while fresh, and fragile after drying. The flower-heads (*Tussilage capitule,* Fr. Cod.) are smaller than those of dandelion, make their appearance in early spring upon scaly scapes, and have a cylindrical involucre of lance-linear scales in a single row, numerous yellow narrowly ligulate pistillate ray-florets in several rows, and about 20 tubular staminate disk-florets. The pappus is long, silky-hairy, and white. The dried flowers and leaves are inodorous and have a mucilaginous, bitterish, and somewhat astringent taste.

Constituents.—All parts of the plant contain a bitter, water-soluble glucoside, a little tannin, resin, gum, and one or more aromatic principles. From the leaves have

been obtained a small amount of an acrid volatile oil, wax, caoutchouc, and 17 per cent. of ash. The odor of the drug indicates the presence of a volatile constituent other than the volatile oil above referred to, which, reasoning by analogy, may be supposed to result from decomposition, probably of the glucoside.

Fig. 455.

Tussilago: rhizome (Nat.).

Fig. 456.

Tussilago: leaf (½ Nat.).

Action and Uses.—Coltsfoot is demulcent and slightly tonic. It is popularly used in the treatment of bronchitis and other pulmonary affections, taken usually in decoction or infusion (1 ounce to the pint [30 Gm: 480 Cc.]). The dried root is sometimes smoked by the natives of Germany and Sweden for the relief of cough. The dose of the decoction is from ½ to 1 ounce (16–30 Cc.). The expressed juice is also employed.

Allied Products.—Several species of the closely related genus *Petasites* are similarly used. In Japan, the flower-shoots of *P. Japonica* Miq. are used in decoction for treating heavy colds, under the name *Makayo*.

U.

ULMUS, *U. S.*—Elm; Slippery Elm.

Ulmi cortex, Cortex ulmi interior.—Elm-bark, Red, Sweet, Moose, or *Rock Elm,* E.; *Ulmeurinde, Rüsterrinde,* G.; *Orme fauve, Orme champêtre,* Fr.; *Olmo,* Sp.; *Ulmeiro,* Port.

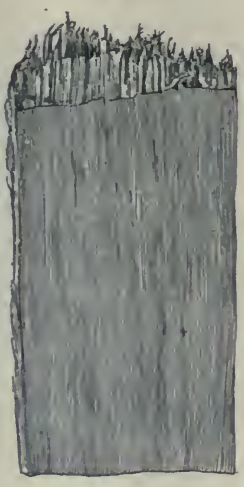
The bark of *Ulmus fulva* Mx. (Fam. *Ulmaceæ*), deprived of its periderm.

The French Codex recognizes also that of *U. campestris* L. of Europe.

Origin.—The Red elm is a tree of eastern and central North America, growing usually in rocky soil, and reaching an extreme height of about 25 M. (75 to 80 Ft.) and a trunk diameter of 1 M. (3 Ft.). It is distinguished by the rough-hairy twigs and leaves, the red wood, which is much less tough and durable than that of the American elm, and the mucilaginous inner bark. The whole of the outer bark should be removed. The inner bark of the trunk and large branches is usually dried under pressure, to preserve its flat or "slab" form. Sometimes the bark of smaller branches is torn off in strips, with the outer bark imperfectly removed.

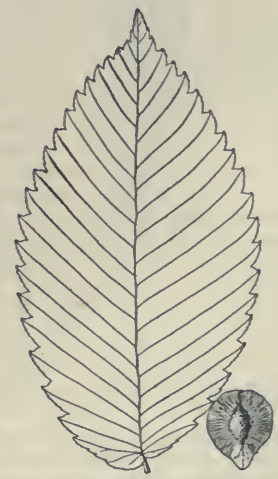
Description.—In flat pieces, varying in length and width, 3 to 4 Mm. thick; outer surface light brown, with occasional dark-brown patches of the periderm; inner surface yellowish brown; fracture fibrous and somewhat mealy; odor slight but distinct; taste mucilaginous. Ground elm contains a few nearly spherical starch grains from 0.005 to 0.010 Mm. in diameter. It should be nearly free from cork-cells. Ground elm-bark is very largely subject to

FIG. 457.



Ulmus (Nat.).

FIG. 458.



Ulmus leaf (½ Nat.); fruit (⅔ Nat.).

adulteration with damaged flour and other starchy substances. *European elm-bark,* chiefly from *U. campestris* L., but occasionally from the *European Black elm, U. effusa* Willd., is of a darker cinnamon-brown on both surfaces and is less mucilaginous, and bitterish and somewhat astringent.

Constituents.—The only important constituent of elm-bark is its large quantity of gum, forming a mucilage which is precipitated by lead acetate, but from which alcohol separates a gelatinous liquid. There is very little starch. The European varieties contain a glucosidal tannin, a bitter principle, and no starch. There appears to be a slight amount of tannin in the official elm-bark also, but not enough to be of practical importance. The ash should not exceed 10 per cent. and is usually less than 9 per cent.

Action and Uses.—Slippery elm bark is demulcent and somewhat nutritious. Made into lozenges with sugar, it is employed to relieve the irritation and cough of

pharyngitis, laryngitis, and bronchitis. In diarrhœa, dysentery, and inflammations of the urinary passages, the mucilage of slippery elm will frequently act as a soothing, diuretic draught. In some parts of the United States slippery elm poultices are popular in the treatment of abscesses, felons, and other local inflammations. It has been asserted to be a remedy in tape worm. The bark, either whole or shredded, and made into tents, has been used to dilate the os uteri, fistulæ of the rectum and other fistulous openings. The mucilage is given in the dose of from ½ to 2 ounces (16–60 Cc.).

The family *Ulmaceæ*, or *Elm family*, is of little economic importance outside of the genus *Ulmus*.

The bark of various species of *Celtis* is rich in tannin and is used as an astringent, and the fruits of one or two species are barely edible.

UMBELLIFERÆ (The Parsley Family).

This is a very large and important family of plants, comprising about 180 genera and more than ten times that number of species, mostly inhabiting temperate regions. The family is chiefly distinguished for its aromatic properties. Outside of their medicinal uses, these aromatic constituents are considerably employed in perfumery, and impart agreeable flavor and wholesomeness to such edible products as carrots, celery, parsley, parsnips, and the delicious but little known Andean rhacachi. Except for these uses, the economic value of the Umbelliferæ is almost wholly medicinal. Although the medicinal properties are in no instance of first rank, yet the number of species which have been employed is very large, and their historic interest is both ancient and great. A few species contain poisonous, bitter constituents, either alkaloids or amaroids, and have been considered under CONIUM. Elsewhere, the medicinal constituents are volatile oils, oleo-resins, variously associated with one another and with gum. The general nature and properties of these constituents have been considered under AJOWAN, AMMONIACUM, ANETHUM, ANGELICA, ANISUM, ASAFŒTIDA, CARUM, CORIANDRUM, CUMINUM, FŒNICULUM, GALBANUM, LEVISTICUM, and SUMBUL, and in our general article on VOLATILE OILS. Of the large number of secondary drugs, the properties and uses agree so closely with those of the preceding, chiefly as carminatives and diuretics, that they are specially interesting from the standpoint of identification and constituents. Every now and again one of them is introduced to pharmaceutical literature with strong claims to the possession of special properties, as was recently the case with the "Osha, or Colorado cough cure," only to fall later to the level of the aromatic stimulants of the family in general. The following unofficial drugs of this family are worthy of special notice:

Thapsia, Fr. Cod. (*Thapsia*, G.; *Faum fenouil*, Fr.; *Tapsia*, Sp.), is the resin of *Thapsia garganica* L., a stout, yellow-flowered perennial of the Mediterranean region. The name is also applied to the root, which is sometimes used under the name *Spanish Turpeth-root*. There is some question whether the African *T. Silphium Viv.* is a distinct species, as we believe to be true. Its resin is more active than that of the former. The fresh root acts as a cutaneous poison, and its collectors suffer severely from symptoms similar to those of rhus-poisoning. The activity resides chiefly in the bark, which is largely collected separately for native use. *T. maxima* Lam. and *T. villosa* Mill., of the same region, are similarly employed. The root is sometimes nearly a yard in length, tapering from a thickness of 2 or 3 inches, and little branched. It is whitish internally. Commercial thapsia resin varies exceedingly in physical properties, according to the method of preparation and consequent degree of purity. The undried root should be washed with cold water, dried, powdered, and extracted with alcohol, which is then evaporated to obtain the crude resin. This is repeatedly washed with boiling water to remove the gum, then again dissolved in alcohol, and the latter evaporated. It should be of a golden-yellow color, softening at a temperature of about 60° F.(15.5° C.) It consists of two acids, a liquid one (*coprylic* or *octoxic*) and a crystalline one (*thapsic*), which is probably an oxidation product of the former. In many samples there is found a third substance, intensely irritant. The powdering of the bark and preparation of the resin usually cause intense cutaneous irritation to the operators. The crude resin yields a highly aromatic volatile oil, which imparts a blue color to ether.

Opopanax, Fr. Cod. (*Hercules' All-heal*, E.; *Opoponaso*, Sp.), is an oleo-gum-resin, obtained from incisions made in the root and stem-base of *Opopanax Opopanax* (L.) Lyons (*Pastinaca O.*—L., *Ferula O.* L.; *O. Chironium* Koch), a large, perennial, yellow-flowered, and yellow-juiced herb of southern Europe.

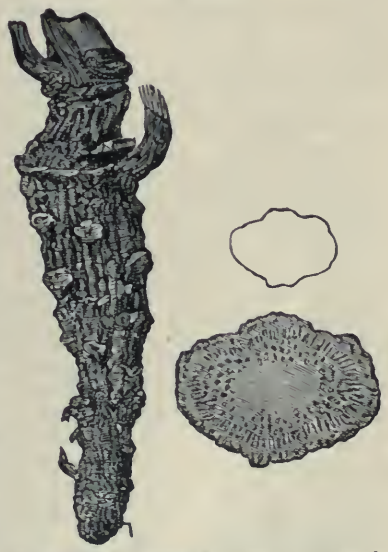
The best quality of opopanax is in irregular, angular, or subglobular pieces, from the size of a pea to that of a waluut, red brown or yellowish brown, friable, breaking with a flat, somewhat waxy fracture, and frequently with vegetable fragments adhering. It has a strong, unpleasant odor, a balsamic bitter taste, yields with water a yellowish emulsion, and when heated softens and exhales a peculiar, not unpleasant, sometimes slightly alliaceous odor. It consists of about one-third gum and nearly one-half resin, with a small quantity of wax and

volatile oil. The volatile oil yields a light portion smelling like lovage oil, a heavier blue portion, and a white, crystalline, sublimable body, *oponal* ($C_{20}H_{10}O_7$), melting at 133° to 134° C. (271.4°–273.2° F.). Genuine opopanax is now rare in commerce, being replaced, according to Holmes, by a myrrh-like substance from *Commiphora Kataf* (Kunth) Engler. This yields up to 10 per cent. of a greenish-yellow lævogyre volatile oil of a specific gravity of 0.870 to 0.905, the "opopanax oil" of commerce. Opopanax had many uses among the ancients, but is now only occasionally employed, then much like ammoniac.

Sagapenum is a similar oleo-gum-resin, obtained in Persia from *Ferula Persica* Willd. It is met with in yellowish-brown, somewhat translucent small tears, and is frequently agglutinated to larger pieces, of a bitter, acrid taste, and a faint, alliaceous odor, which becomes prominent in heating. Cake sagapenum is soft, adhesive, brown, nearly free from tears, mixed with foreign matters. A mixture of galbanum and asafœtida is sometimes sold in place of sagapenum. Pelletier and Brandes found in sagapenum 50 to 54 per cent. of gum, with small quantities of volatile oil, bassorin, etc.

Imperatoria (*Rhizoma imperatoriæ, ostruthii* or *astrantiæ; Masterwort, Felonwort,* E.; *Meisterwurz, Kaiserwurz, Ostranz,* G.; *Imperatoire,* Cod.) is the rhizome of *Imperatoria Ostruthium* L. (*Peucedanum O.*—Koch; *Oreoselinum officinale* Link) of Europe. The drug is dark gray brown, 5 to 10 Cm. (2 to 4 In.) long, up to 1.5 Cm. ($\frac{3}{5}$ In.) thick, tapering, heavily wrinkled longitudinally, finely annulate, heavily scarred; internally whitish, the bark thin, the pith large, the yellowish wood-bundles small, in a loose circle, the bark and pith containing numerous brown resin-cells. Imperatoria is aromatic and of a bitter and pungent taste. The drug contains crystalline ostruthin and imperatorin, and 0.75 per cent. of volatile oil composed of a hydrocarbon and an oxygenated body, probably angelic aldehyd. *Ostruthin* ($C_{18}H_{20}O_3$), when fused with caustic potash, yields a resorcin and acetic and butyric acids. *Imperatorin* occurs in shining crystals, which are generally tasteless, but acquire a pungent taste when dissolved in alcohol.

Fig. 459.



Imperatoria Ostruthium Linné: root-stock (Nat.): transverse section (Nat.).

Peucedanum officinale L., similarly employed, is a root. It is darker without and within, and contains resin-cells in the medullary rays of the wood. More than a dozen other of the 160 species of *Peucedanum* have similar properties, of some the roots, of others the fruits, being employed.

Pimpernel or *Pimpinella* (*Radix Pimpinellæ,* P. G.; *Burnet saxifrage, Small saxifrage* or *Pimpernel, Breakstone,* E.; *Pimpernell, Bibernell,* G.; *Grand Boeage,* Fr.) is the dried rhizome and root of *Pimpinella Saxifraga* L. or of *P. magna* L., of Europe. It tapers from a thickness of about 1 to 1.5 Cm. ($\frac{2}{5}$–$\frac{3}{5}$ In.). It is brownish, wrinkled, and above somewhat annulate. The wood is yellowish and nearly as thick as the whitish bark. It is aromatic, sweetish, pungent, and bitterish. It contains considerable resin and volatile oil. The latter is of a golden yellow, has a specific gravity of 0.959, a disagreeable odor, and a bitter and somewhat acrid taste.

Black Pimpinella (*P. nigra* Willd.) yields a blue oil which turns green in the sunlight.

Eryngium or *Eryngo* (*Button-* or *Corn-snakeroot, Rattlesnake-master, -flag* or *-weed*) is the rhizome of *Eryngium aquaticum* L. (*E. yuccæfolium* Mx.) of the eastern and central United States. The plant grows in rather low grounds. It bears a dense tuft of radical leaves which are 1 or 2 feet long, linear, tapering, pungently serrate-toothed and pale green. The stout stem is 2 or 3 feet high, clothed with similar leaves, which are successively smaller upward, and terminates in a panicle of dense ovate heads of greenish-white flowers. The rhizome is 6 to 12 Mm. ($\frac{1}{4}$–$\frac{1}{2}$ In.) long, with numerous short branches, terminating with a more or less deeply cup-shaped scar. A transverse section exhibits a large whitish central pith and several short wood-wedges, separated from the bark by a brown cambium-line. Below, the root-stock is divided into a large number of nearly simple roots from 5 to 8 Cm. (2–3 In.) long, containing a rather thick and soft whitish meditullium. Button snakeroot has a dark-brown color externally, a slight but rather heavy aromatic odor, and a sweetish and somewhat acrid and aromatic taste, recalling that of parsnip. Its constituents are unknown, but it doubtless contains volatile oil, resin, and bitter substances.

The genus *Eryngium* contains probably 175 species, nearly a score of which have been medicinally employed, especially *E. campestre* L., the European *Eryngo* (*Mannstren, Buchdistil,* G.; *Chardon-Roland, Penicant,* Fr.), the root of which is cylindrical, about 2.5 Cm.

(1 In.) thick and a foot or two long, several headed, dark brown, the thick bark white internally, the wood yellowish.

Laserpitium, Laserwort, White Gentian, or *Herb Frankincense* (*Radix gentianæ albæ* or *R. Cervariæ a.*—*Weisser Enzian, Laserkraut,* G.) is the root of *Laserpitium latifolium* L., an European perennial herb. In shape it resembles gentian root, but it is externally brownish white, internally white, and contains yellow resin-cells in the thick spongy bark. Kutz (1883) isolated from it bitter *laserpitin* ($C_{15}H_{22}O_4$), which separates from hot benzine in monoclinic crystals, and is easily soluble in chloroform, ether, benzol, and carbon disulphide.

Sanicula or *Sanicle* (*Black Snakeroot, Pool-root,* E.; *Sanikel,* G.; *Sanicle,* Fr.; *Sanicula,* Sp.) is the root of *Sanicula Marilandica* L., and of other species of *Sanicula,* which have been collected for or with it. The genus is composed of perennial herbs with palmately divided and coarsely serrate radical leaves and irregular or compound umbels, having polygamous, rather capitate flowers, and few-leaved involucels. The fruit is nearly globular, and has the mericarps closely united, without prominent ribs, covered with hooked prickles, and containing 5 oil-tubes. *S. Marilandica* has the radical stem-leaves 5- or 7-parted and the divisions rather narrow. The staminate flowers are numerous and on slender pedicels (the variety *Canadensis* has few and short-pedicelled sterile flowers) and the perfect flowers have elongated and recurved styles. The blackish root and the leaves are nearly inodorous, and have a somewhat bitter and persistent acrid taste. The sanicles were important aboriginal remedies and appear to have rather active aromatic bitter properties. European sanicle is the rhizome and roots of *S. Europæa* L. The term "Black sanicle" is applied to the root of *Astrantia major* L., which is also called *Radix imperatoriæ nigræ.* The oblique rhizome is about 10 Cm. (4 In.) long, and 6 Mm. (¼ In.) thick, blackish brown, annulated and wrinkled, internally whitish. The roots are shrivelled and fragile. Several other species of Astrantia are also used.

Osha, or *Colorado Cough-cure,* is the root of *Ligusticum filicinum* Wats., a perennial herb of Colorado, Utah, and the adjacent region, and is a highly prized expectorant among the aborigines. The entire root is about 1 foot in length, but usually comes in short pieces, sometimes ½ or even ¾ of an inch in diameter. It is usually simple, but occasionally has one or more small parallel branches. It is very dark brown, strongly wrinkled, and somewhat annulate above, where it often presents several crowns. The thick bark is yellow, the wood pale yellow or whitish. The root is highly aromatic and of a pungent taste. Nearly a dozen species of *Ligusticum* are employed for their similar aromatic properties.

Petroselinum or *Parsley* (*Petersilie,* G.; *Persil,* Fr.; *Peregil,* Sp.) is the root of the well-known parsley, *Petroselinum Petrosolinum* (L.) Lyons (*Apium P.*—L.; *Carum P.*—Benth.; *P. sativum* Hoffm.). One of its cultivated varieties produces a large conical root, resembling a carrot. This is cut lengthwise into two or four sections and dried. The entire dried root often exceeds 2.5 Cm. (1 In.) in thickness at the crown, and is 15 to 20 Cm. (6 to 8 In.) long. It is wrinkled, above annulate, and bears transverse corky ridges. In damp weather it is flexible, but when dry it is brittle, with a short fracture, exhibiting a very thick whitish bark, with an inner zone consisting of a dense radiation of rows of resin-cells, with a brown cambium line separating it from the yellow, obscurely radiate meditullium. It is aromatic, sweetish, and somewhat pungent. Besides gum, starch, sugar, and ordinary constituents, parsley root contains a very little volatile oil and *apiin* ($C_{24}H_{28}O_{13}$), which is extracted by hot water or alcohol, becomes gelatinous on cooling, and when dry is converted into a white, tasteless, and odorless powder. Parsley root has little medicinal activity. When fresh it is boiled and eaten as a vegetable. The herbage of the plant is somewhat more aromatic, and is of a greenish-yellow color, a specific gravity of 0.900 to 0.925, and is dextrogyre. It contains little apiol.

FIG. 460.

Parsley root; transverse section (× 3).

Parsley Fruit ("Parsley Seed") is a cremocarp, about 2 Mm. ($\frac{1}{12}$ In.) long and nearly as broad, of a dark brown-gray color, when freshly dried having a greenish tinge. It is ovate, laterally compressed, and each mericarp bears five pale-brown, slender ribs, except for which they are smooth. Each contains 2 vittæ in the face, 4 in the back. The fruit is hard, or slightly gritty between the teeth, and is aromatic, pungent, and slightly sweetish. Parsley fruit has a different taste and odor from the leaves, and the root is much more active. The same is true of its oil, which is sometimes yielded to the extent of 5 or 6 per cent. The oil is thick, greenish yellow, heavier than water (specific gravity 1.05 to 1.10) and slightly lævogyre. Its important constituent is a large but variable amount of apiol, associated with a terpene, and probably pinene. Apiol is also obtained from *Anethum,* but this is not identical with that from parsley, and is more specifically designated as dill-apiol.

More or less confusion exists in regard to the substances commercially known as apiol. True apiol, or parsley camphor, as it is also called, is a crystallizable compound first obtained in 1823 from the volatile oil of parsley seed by Stange, of Basel, Switzerland. Its true chemical character and properties were carefully studied by Ciamician and Silber in 1888 and

1890, and it was shown to be the dimethoxy-methylene ether of allyl-tetraoxybenzene. Its formula is $C_{12}H_{14}O_4$ or $C_3H_5.H\langle\begin{matrix}O\\O\end{matrix}\rangle CH_2.(OCH_3)_2$. Apiol may be obtained from the distilled oil of parsley seed by exposing the same to low temperatures; the German oil frequently being so rich in apiol as to cause it to assume a semifluid condition at ordinary temperature. It occurs in brittle, white, needle-shaped crystals, which melt at 30° C. (86° F.) and boil at 294° C. (561.2° F.), are insoluble in water, but readily soluble in alcohol or ether. It has a slight parsley-like odor and an aromatic burning taste, and is not easily volatilized with the vapor of boiling water. When treated with potassium permanganate, apiol is converted into *apiolic acid*, $C_{10}H_{10}O_6$, which melts at 175° C. (347° F.). Boiling alcoholic solution of potassium hydroxide converts apiol into its isomer, *isoapiol*, melting at 56° C. (132.8° F.) and boiling at 304° C. (579.2° F.).

In 1852 Homolle and Joret applied the name apiol to a liquid obtained by them from an alcoholic extract of parsley seed by means of ether, and subsequently freed from fat by treatment with lead oxide. According to H. C. Whitney, this liquid consists of volatile oil holding a soft resin and true apiol in solution. It is of yellowish color, has a specific gravity of 1.078, and is immiscible with water. It does not congeal even if cooled to —12° C. (22.4° F.).

It is evident that the name apiol should be applied only to the chemical compound described above, and not to the liquid mixture.

A greenish-yellow liquid, said to be obtained by saponification and subsequent distillation of crude oil of parsley seed, has been placed on the market under the name *apiolin*, and is used as an emmenagogue.

Apium or Celery fruit ("Celery Seed," *Fructus apii, Selerie, Eppich*, G.; *Ache celeri*, Fr.; *Apio silvestro*, Sp.) is the fruit of *Apium graveolens*, L., a European biennial herb, well known in cultivation. It is about 1–1.5 Mm. ($\frac{1}{25}$ to $\frac{1}{16}$ In.) long, roundish-ovate, laterally flattened, brown, with lighter-colored ribs, and smooth; the mericarps are usually separate, somewhat curved, flat on the face, and contain about 12 thin oil-tubes; odor and taste agreeably aromatic. The fruit yields 2 or 3 per cent. of a colorless volatile oil, having the characteristic odor and taste of the plant, dextrogyre, and of a specific gravity of 0.870 to 0.895. It is of complex composition, and its characteristic odorous principle is not well known. There is in the market an oil of the fresh herbage which is of more pleasant odor and taste than that of the fruit. Four other species of Apium are reported as in medicinal use.

Carota or *Carrot* (*Fructus carotæ* or *daucæ; Mohre, Gelbe Rübe*, G.; *Carrote*, Fr.; *Zanahoria*, Sp.) is the fruit of *Daucus Carota* L., a biennial herb of Europe and Asia, and the origin of the cultivated vegetable of that name. The fruit is, for medicinal purposes, chiefly collected from wild plants. The plant is a widely diffused and troublesome weed in the eastern United States, covering wide areas of neglected meadowland until the surface is completely white during the flowering period. The strong incurving of the marginal rays of the fruiting umbel has given the name of *Birds'-nest plant*. The fruit is about 3 Mm. ($\frac{1}{8}$ In.) long, oval, dorsally compressed, and grayish brown; each mericarp has five hispid filiform primary ribs, two of which are lateral, the remaining three upon the back; between these are four secondary ribs, two lateral and two upon the back, each beset with long, spiny bristles, and covering one small oil-tube, two additional oil-tubes being upon the nearly flat face. The fruit has a slight aromatic odor and a pungent aromatic taste. It is said to yield up to 1.5 per cent. of a pale-yellow or colorless volatile oil, which is lævogyre, has a specific gravity of 0.870 to 0.923, and a carrot-like odor and taste. It consists chiefly of pinene.

Carrot-root, except for its edible properties, is chiefly valuable for its yellow coloring-matter, *carotin*, which is inert, and is largely used for coloring butter, cheese, and other foods. The root yields 0.011 per cent. of volatile oil, fixed oil, crystallizable and uncrystallizable sugar, mannite, starch, pectose, and malic acid, besides *carotin* ($C_{15}H_{24}O$), which is a peculiar ruby-red, tasteless, and odorless neutral principle occurring in crystals in the root and soluble in ether, chloroform, and soap solution, and with difficulty in water, and *hydrocarotin* ($C_{18}H_{30}O$), in silky, colorless, tasteless crystals.

Fig. 461.

Fruit of phellandrium (× 4½).

Phellandrium (*Fructus phellandrii; Semen fœniculi aquaticæ; Waterdropwort fennel*, E.; *Wasserfenchel, Rossfenchel, Pferdfenchel*, G.; *Pfellandrie aquatique, Fenouil d'eau*, Fr.) is the fruit of *Œnanthe Phellandrium* Lam. (*Phellandrium aquaticum* L.), a biennial herb of Asia and Europe, where it grows in wet places. The fruit (see Fig. 461) is 3 to 5 Mm. ($\frac{1}{8}$–$\frac{1}{5}$ In.) long, ovate-oblong in shape, scarcely compressed, and narrowed above. The three dorsal ribs are broad and obtuse, the two lateral ones larger, the four grooves narrow, each with a single oil-tube, and two additional oil-tubes in the face of each mericarp. It is of a brown, and when collected in an unripe state, of a blackish-brown color, and has an unpleasant odor, recalling that of caraway, and a bitterish, somewhat acrid taste.

It yields up to 2.5 per cent. of a volatile oil, of a light-yellow to a brownish color, according to age, a strong and penetrating odor and burning taste. It has a specific gravity of 0.85 to 0.89, is dextrogyre, and consists chiefly of phellandrene.

Hydrocotyle (*Water* or *Indian Pennywort, Shilling-grass, Fairy tables,* E.; *Wassernabel,* G.; *Bevilacqua,* Fr.; *Hydrocotila,* Sp.) is the herbage of *Centella Asiatica* (L.) Urban (*Hydrocotyle Asiatica* L.; *H. repanda* Pers.), an herb of wet places in most tropical and subtropical regions. The stem is creeping, the leaves smooth, situated in tufts on the nodes of the stem, have petioles with a sheathing base, are roundish-reniform in outline, with a somewhat crenate margin, about 25 Mm. (1 In.) broad, rather thick, radiately veined, and dark green. The pink-colored flowers are in small umbellate clusters of about 3, and produce small, laterally flattened, suborbicular fruits without oil-tubes. The plant is inodorous, but in bruising the fresh leaves a peculiar odor is developed; the taste is bitterish and pungent. The active principle is supposed to be *villerin,* an oily liquid having a bitter taste, a strong, peculiar odor, becoming viscous on exposure, insoluble in potassa solution, and soluble in ammonia, diluted alcohol, and ether. A dozen species of the closely related genus *Hydrocotyle* have similar uses in various countries.

Heracleum or *Cow-parsnip, Madness* or *Madnep,* is the leaves and root of *Heracleum lanatum* Mx., a gigantic perennial woolly herb of North America, which possesses acrid and poisonous properties. The root is many-headed, fleshy, nearly simple, or composed of many thinner branches, 12 Mm. ($\frac{1}{2}$ In.) or less in diameter, brownish yellow externally, white internally, with a rather thick bark containing resin-cells. The leaves are large, ternately dissected, on very broad and sheathing petioles, the segments often 25 Cm. (10 In.) long, the middle one usually three-lobed. The umbels are from 30 to 38 Cm. (12–15 In.) broad, with an involucre of oblong-lanceolate leaves and involucels composed of 5 to 8 lanceolate, slender, acuminate leaves. The flowers are white. The fruit is 8 Mm. ($\frac{1}{3}$ In.) long, oval, flattened on the back, broadly winged on the margin, each mericarp with 5 slender ribs, the lateral ones being close to the margin, and in upper half with 6 clavate oil-tubes, 2 of which are in the commissure. All parts of it have a rank odor and a pungently acrid taste. In their fresh state the leaves and also the root, applied to the skin, may produce vesication, and have been used as counter-irritants. Some of the European species are still more irritant, and contain a juice which has been applied to warts as an escharotic. The American plant has been used with alleged curative effect in epilepsy, apparently depending upon gastro-intestinal irritation. It is given both in substance and in infusion, and is thought to correct dyspeptic disorders. 1 drachm (4 Gm.) of the root or its equivalent in infusion may be taken several times a day. The *European Cow-parsnip* (*Bärenklaue,* G.; *Berce, Fausse acanthe,* Fr.), having similar properties, is *H. spondylium* L.

Selinum or *Marsh-parsley* (*Radix olsnitii; Sumpfsilge, Elsinich,* G.; *Selin de marais,* Fr.), the root of *Selinum palustre* L. (*Thysselinum p.*—Hoffm.; *Peucedanum p.*—Moench), of wet lands in Europe, has quite similar properties to those of Heracleum, and the fresh juice is similarly vesicant. The root is about 15 Cm. (6 In.) long, in the upper part nearly 25 Mm. (1 In.) thick, 1- or several-headed, annulate above, with deep longitudinal wrinkles, grayish brown, and with scattered whitish suberous warts. The bark is thick, spongy, and brown, and contains a circle of rather large laticiferous vessels; the meditullium is soft and often radially cleft. The root has a strong, disagreeable, somewhat terebinthinate odor and a pungent and acrid taste.

The root of *S. Benthami* Watson is used in Japan under the name *Seng-kin.* More than 100 other species of this family, chiefly in the genera *Lichtensteinia, Bupleurum, Ammi, Sium, Scandix, Anthriscum, Chærophyllum, Prangos, Æthusa, Seseli, Athamanta, Thaspium, Pastinaca, Caucalis,* and *Bifora,* might be named as possessing similar constituents, properties, and uses, either among medical men or by aborigines.

UNGUENTA.—Ointments.

Pommades, Onguents, Fr.; *Salben,* G.; *Unguentos,* Sp.

Ointments are unctuous preparations of such consistence as to permit of their application to the skin by friction or inunction; in contact with the body they are gradually liquefied.

In the preparation of ointments it is of importance that perfectly smooth, homogeneous mixtures be obtained, and that the fatty vehicle be absolutely free from rancidity, since they are often applied to tender excoriated surfaces, and would otherwise prove a source of irritation instead of a soothing application.

Ointments should be preserved in well-glazed, covered porcelain jars, and kept in a dry, moderately cool place. The true porcelain jars, although somewhat expensive, are to be preferred, as they are strictly impermeable to grease and can be thoroughly cleaned with hot water and lye whenever empty. Glass stock jars are offered at a much lower

price, but will often crack while being cleaned, particularly with hot water, yet they are vastly superior to the ordinary white china or queensware covered jar, since the glazing of the latter soon becomes full of fine cracks, through which the fat permeates and, gradually turning rancid, contaminates the contents of the jar; moreover, no amount of washing will remove the rancid grease entirely from the pores of the jars, hence they soon become unfit for use. The sweet condition of ointments cannot be preserved without proper care and cleanliness.

Ointments may be conveniently divided into distinct classes in regard to their therapeutic effect, thus: 1. Protective ointments, which are non-absorbable in character and act strictly epidermatically—that is, on the outer skin or cuticle. 2. Emollient ointments, which have nutritive or absorbefacient properties and act endermatically or by penetrating into the skin. 3. Ointments which produce systemic or constitutional effects, and must therefore be absorbable, penetrating not only into, but through, the skin. This difference in the therapeutic effects desired necessitates careful selection of the vehicle intended for exhibition of the medicinal agents. Non-absorbable ointments intended to produce some medicinal effect on the outer skin, such as astringent, counterirritant, antiseptic germicidal or similar effect, or possibly as protective agents, may therefore be made with petrolatum or a mixture of the same with hard paraffin, which latter combination is to be preferred in warm weather on account of its higher fusing-point. (See UNGUENTUM PARAFFINI.) For emollient ointments designed to penetrate the skin for the purpose of producing a deeper local effect, such as anodyne, stimulant, resolvent, etc., preference should be given to lard, lard mixed with wax, lard and oil, oil and wax, or oil, wax, and spermaceti. The lard to be used for ointments should be free from water and other impurities. The absorbent properties of these bodies permit the admixture of medicinal agents in the form of solution either in water, alcohol, glycerin, oleic acid, or oil. In the last group of ointments, which are intended to produce systemic or constitutional effects, vehicles should be employed which penetrate not only into, but through, the skin, thereby permitting the absorption of the remedial agent present. No substance is known to possess these properties to a greater degree than wool-fat and its official representative, lanolin, which is itself closely related to the fat secreted by the sebaceous glands of the human body. Lanolin can readily be combined with its own weight of water and even larger quantities, whereas lard takes up only about ½ of its weight of water and soft paraffins not more than 10 per cent.

The official glycerite of starch is sometimes used by physicians under the name of *plasma* or *plasma glycerini* as a vehicle for ointments, in place of lard or petrolatum. It possesses the advantage of not being of a fatty nature, and hence easily removed by washing with water, and never becoming rancid; but as it is somewhat hygroscopic it must be preserved in well-closed jars.

As regards the mode of preparation of ointments, three distinct methods are followed, namely, by fusion, by incorporation of the medicinal agent with a suitable vehicle, and by chemical action. When ointments are to be made by fusion, those constituents having the highest fusing-point, as wax and spermaceti, should be heated first, and when nearly melted the lard or oil added, bearing in mind that as long as some of the particles remain unmelted there is no danger from the continued application of heat, which should, however, be withdrawn in time to avoid a rise in temperature of the melted fats. Fusion of ointments is preferably performed on a water-bath, in round-bottom pans or evaporating-dishes, and if dirt be present the melted mixture may be decanted, or, if necessary, strained through cheesecloth into a previously warmed dish or mortar; the liquid should then be stirred until a homogeneous soft mass results, after which it may be set aside and allowed to stiffen by further gradual cooling. The stirring of melted fats while cooling is essential to insure a perfectly smooth product, since fats are composed of solid and liquid bodies, which, during the cooling process, become partially separated, producing a granular solid on congealing, if allowed to cool at perfect rest, as may be seen in the case of plain lard; moreover, in a mixture of melted fats those having a higher fusing-point would naturally congeal earlier than the rest; therefore, unless an intimate mixture be kept up by constant stirring, separation would ensue and a lumpy ointment result. The point of danger may be said to have been passed when the melted ointment has so far cooled under continued stirring that a uniform thick, creamy mass is obtained; for stirring, a broad wooden spatula will be found advantageous. When large quantities of aqueous liquids are to be incorporated with melted fats, as in the case of rosewater

ointment, the liquid should be warmed and then slowly added, with constant trituration, to the mixed fats previously somewhat cooled; otherwise the less fusible constituents will be chilled by the cold liquid and separate in granular form, thus preventing a smooth ointment.

Ointments prepared by incorporation of medicinal agents with an appropriate vehicle comprise by far the larger number of official ointments, and practically all those prescribed extemporaneously. Benzoinated lard and simple ointment are alone directed by the Pharmacopœia as vehicles, although physicians frequently use petrolatum or the commercial products known as vaseline and cosmoline; when absorption of the ointment is desired, wool-fat, known as lanolin, is decidedly to be preferred. All substances to be mechanically incorporated in an ointment must be in the form either of solution or an impalpable powder; the latter condition, in the case of vegetable substances, can be attained only by passing the powder through a fine bolting-cloth sieve (about No. 120). The incorporation may be effected either in a mortar or on a heavy glass slab by means of a broad spatula, the finely powdered substance being first mixed with a small quantity of the vehicle, and, when a smooth mixture has been obtained, the remainder added; while an ointment slab is, as a rule, preferred in this country, the mortar is used almost exclusively in Europe, and for some ointments is in fact indispensable, particularly when solutions are to be added.

When the quantity of powder to be added is large, it will prove advantageous to melt some of the vehicle and mix this with the powder, in a warm mortar, before adding the remainder. Some substances can be conveniently brought into a smooth condition by triturating with a little olive, or expressed almond, oil, such as calomel, lead carbonate, bismuth subnitrate, zinc oxide, etc., as well as certain crystallizable bodies, like mercuric chloride and silver nitrate; for the latter a little oil is decidedly better than water, since upon the gradual evaporation of the latter a return to the crystalline state is probable, giving rise to the presence of minute gritty particles which would cause irritation. Opium should be rubbed smooth with about an equal weight of water, and then at once incorporated with the fatty vehicle before the paste begins to dry. Some salts may be dissolved in water, provided they are very soluble, as potassium iodide, while others must be reduced to an impalpable condition by trituration, as lead acetate, tartar emetic, zinc sulphate, etc. Red mercuric oxide, iodoform, naphthalene, and boric acid may be triturated with a few drops of alcohol, in a mortar, until rendered impalpable; camphor should be powdered, by the aid of alcohol, just before it is to be used, and added to the ointment after all other ingredients have been incorporated, since it is soluble in the fat and materially softens its consistence, which, in the case of solid extracts, would interfere considerably with their perfect admixture.

Whenever extracts, such as belladonna, opium, stramonium, and the like, are to be exhibited in ointments, the pilular extracts are to be preferred, for, after having been softened with a small quantity of water or diluted alcohol, they are readily incorporated with the fatty vehicle, producing a perfectly smooth mixture free from gritty particles. For the extracts of belladonna leaves and of opium, water is to be preferred; but for extract of stramonium leaves diluted alcohol should be used; and in every case an excess of solvent must be avoided, for if the extract be converted into a fluid it cannot be well mixed with the fat; the consistence of a paste resembling honey or thick syrup is best. Another important point in the admixture of solid extracts with ointments is to mix the former with a small portion of the vehicle immediately after they have been softened, and not to allow them to remain on the ointment slab, so as to avoid the drying out of the paste around the edges, which would cause separate particles to appear in the finished products.

Iodine, before admixture with fats, is preferably dissolved in a small quantity of water, with the aid of a little potassium iodide, as it cannot readily be rubbed into a very fine powder by itself.

Substances which are wholly or partly soluble in fats, such as menthol, salol, chrysarobin, benzoic and carbolic acids, aristol, naphthol, and the like, should be triturated in fine powder form with a portion of the vehicle liquefied by heat, and, after addition of the remainder, the mixture must be continually stirred until cold. If chloral, thymol, naphthol, or salol be ordered, together with camphor, in an ointment, the two substances must be triturated together until an oily fluid results, which can then be readily incorporated with the vehicle.

Alkaloidal salts may be incorporated in ointments in solution in water or, if present in large quantity, may be added in the form of a very fine powder; but whenever pure alkaloids are ordered by physicians these should be triturated with a small quantity of warm oleic acid before they are mixed with the fatty vehicle, as more intimate distribution is thus effected than if the alkaloids be merely rubbed into a smooth paste with olive or almond oil.

Glycerin should never be used in place of oil or water to produce a smooth paste with vegetable or mineral powders, because, although derived from fats, it can be incorporated with them permanently only with difficulty. When glycerin in considerable quantity is ordered to be added to an ointment consisting chiefly of lard or a mixture of lard or oil with wax, the addition of a small proportion of anhydrous wool-fat, in place of a like quantity of the regular vehicle, will overcome all difficulty of incorporation. A similar expedient will prove most valuable when large quantities of aqueous fluids are to be incorporated in ointments, or in the case of alcoholic liquids, which ordinarily mix with fats with great difficulty. The pharmacist, in preparing ointments containing fluids, must so combine the constituents that a permanent homogeneous mixture results, from which the fluids will not separate on standing.

Whenever substances likely to attack metal are ordered in ointments, the incorporation with the fatty vehicle should never be made with steel spatulas, but always with horn or rubber-coated ones; the latter can now be had quite pliable, and are admirably adapted for ointments containing salicylic acid, tannic acid, iodine, mercuric chloride, etc.

Ointments should always be dispensed in glass or porcelain jars provided with suitable covers; if the latter be of metal or wood, a disk of heavy paraffin paper should be inserted, to avoid contact with the fatty substance. The compressible tubes used by artists have been found very desirable for dispensing soft ointments. Under no circumstances, *except when intended for immediate use*, should ointments be put up in wood boxes, as the fat will readily penetrate the material and thus become exposed to oxidation by the air. When ointment jars are returned to be refilled, they should be carefully wiped out with soft paper and washed thoroughly before the new ointment is put in; a fresh disk of paraffin paper should also be inserted, and a new label be put on the jar if the old one has become soiled.

To clean the apparatus in or on which ointments have been prepared, the best plan is first to wipe off all remaining grease with clean sawdust of soft paper, and then to wash it well with warm water and lye or soap. In the case of iodoform ointment a few drops of oil of turpentine will readily remove the characteristic odor.

UNGUENTUM, *U. S.*—Ointment.

Unguentum cereum, P. G.; *Unguentum simplex; Unguentum adipis.—Pomade simple*, Fr.; *Simple ointment*, E.; *Wachssalbe*, G.

Preparation.—White wax, 200 Gm.; benzoinated lard, 800 Gm. Melt the white wax, add the benzoinated lard, and heat gently until liquefied; then stir the mixture until it congeals.—U. S.

Simple ointment of the German Pharmacopœia consists of 30 per cent. of yellow wax and 70 per cent. of olive oil.

Uses.—White wax has been substituted for yellow in the present Pharmacopœia. Simple ointment is used as an emollient application to excoriations and sores, but more frequently as a base for other substances intended for local application.

UNGUENTUM ACIDI BORICI, *U. S., Br., P. G.*—Ointment of Boric Acid.

Pommade de l'acide borique, Fr.; *Borsalbe*, G.

Preparation.—Boric acid, in fine powder, 100 Gm.; paraffin, 100 Gm.; white petrolatum, 800 Gm. Melt the paraffin, add the white petrolatum, and heat gently for 10 minutes. Then gradually add the hot liquid to the boric acid, contained in a warm mortar, triturating thoroughly, and stir the mixture until it congeals.—U. S.

To make 1 troyounce of the ointment, melt 48 grains of paraffin, add 384 grains of white petrolatum, and heat gently for 10 minutes; gradually add the warm liquid to 48 grains of very finely powdered boric acid and stir until cold.

The British and German pharmacopœias both direct 1 part of finely powdered boric acid to be mixed with 9 parts of paraffin ointment.

Uses.—This is a mildly antiseptic ointment, to be used in burns, abrasions, inflammations of the eyelids, etc.

UNGUENTUM ACIDI SALICYLICI, *Br.*—Salicylic Acid Ointment.

Pommade de l'acide salicylique, Fr.; *Salicylsalbe*, G.

Preparation.—Salicylic acid, in powder, 10 grains; paraffin ointment, 490 grains. Mix.—Br.

Uses.—This preparation may be applied to skin eruptions in which salicylic acid will be of benefit.

UNGUENTUM ACIDI TANNICI, *U. S.*—Ointment of Tannic Acid.

Pommade de tannin, Fr.; *Tanninsalbe*, G.

Preparation.—Tannic acid, 20 Gm.; glycerin, 20 Gm.; ointment, 60 Gm. Dissolve the tannic acid in the glycerin, with the aid of a gentle heat, and mix the solution thoroughly with the ointment in a mortar, avoiding the use of iron utensils.—U. S.

To make a troyounce of the ointment, dissolve 96 grains of tannic acid in 96 grains of glycerin and incorporate the solution with 288 grains of ointment.

Uses.—The addition of glycerin in this formula enhances the effect of the tannic acid. The ointment is of service in hemorrhoids, prolapse of the rectum, chronic vaginitis, and sluggish ulcers.

UNGUENTUM ACONITINÆ, *Br.*—Aconitine Ointment.

Pommade d'oléate d'aconitine, Fr.; *Akonitinoleatsalbe*, G.

Preparation.—Aconitine, 10 grains; oleic acid, 80 grains; lard, 410 grains. Rub the aconitine with the oleic acid and gently warm; when solution has been effected, add the lard and mix.—Br.

It would seem proper to designate this preparation as ointment of aconitine oleate, the alkaloid to the extent of 2 per cent. being held in solution by an excess of the acid.

Uses.—Ointment of aconitine is a powerful local anæsthetic, used chiefly for the relief of supraorbital neuralgia. If applied to the mucous membranes or abraded skin surfaces, enough aconitine may be absorbed to produce symptoms of poisoning.

UNGUENTUM ADIPIS LANÆ, *P. G.*—Wool-fat Ointment.

Pommade de gras de laine, Fr.; *Wollfetssalbe*, G.

Preparation.—Anhydrous wool-fat, 20 parts; water, 5 parts; olive oil, 5 parts. Melt the wool-fat with the aid of gentle heat and incorporate the oil and water.—P. G.

Uses.—This ointment corresponds to Adeps Lanæ Hydrosus, U. S. P. (which see).

UNGUENTUM ANTIMONII ET POTASSII TARTRATIS.—Antimonial Ointment.

Pommade stibiée, Fr. Cod.; *Unguentum tartari stibiati*, P. G.; *Ointment of tartrated antimony*, E.; *Pommade d'Autenrieth*, Fr.; *Brechweinsteinsalbe, Pockensable*, G.

Preparation.—Antimony and potassium tartrate, in very fine powder, 2 parts; paraffin ointment, 8 parts. Mix.—P. G.

The ointment of the French Codex is somewhat stronger than the German, being made by mixing 1 part of the finely powdered tartar emetic with 3 parts of benzoinated lard.

Uses.—Antimonial ointment may be employed whenever a powerful counterirritant effect is desired, but the painful ulcers and sloughs it sometimes occasions have caused its use to be generally abandoned.

UNGUENTUM AQUÆ ROSÆ, *U. S., Br.*—Ointment of Rose Water.

Cold Cream, Fr. Cod.; *Unguentum leniens*, P. G.; *Unguentum emolliens.*—*Cold Cream*, E., Fr., G.

Preparation.—Spermaceti, 125 Gm.; white wax, 120 Gm.; expressed oil of almond, 560 Gm.; sodium borate, in fine powder, 5 Gm.; stronger rose water, 190 Gm.; to make about 1000 Gm. Reduce the spermaceti and the white wax to fine shavings and melt them at a moderate heat, add the expressed oil of almond and stir, continuing the heat until the mixture is uniform; then gradually add the stronger rose water, previously warmed, in which the sodium borate has been dissolved, stirring the mixture rapidly and continuously until it congeals and becomes of uniform consistence.

When this ointment is to be used as a vehicle for metallic salts, the sodium borate should be omitted.—U. S.

To make 1 pound of cold cream use 2 avoirdupois ounces of spermaceti, 835 grains of white wax, 8 avoirdupois ounces and 420 grains of expressed oil of almond, 3 avoirdupois ounces and 18 grains of stronger rose water, and 40 grains of sodium borate.

Both the British and German pharmacopœias omit the sodium borate and use a larger proportion of water. The former directs that 1½ ounces each of spermaceti and white wax be melted with 9 ounces of almond oil, the mixture poured into a warmed mortar and 7 fluidounces of rosewater and 8 minims of oil of rose then incorporated therewith. The German directions are to melt together 7 Gm. of white wax, 8 Gm. of spermaceti, and 57 Gm. of oil of almond, add 28 Gm. of water, beat the whole to a creamy consistence and add 2 drops of oil of rose.

Uses.—This elegant preparation enjoys deserved popularity as a soothing, cooling application for chapping of the hands and face, abrasions, and other superficial lesions of the skin.

UNGUENTUM ATROPINÆ, *Br.*—Atropine Ointment.

Pommade d'oléate d'atropine, Fr.; *Atropinoleatsalbe*, G.

Preparation.—Atropine, 10 grains; oleic acid, 40 grains; lard, 450 grains. Rub the atropine with the oleic acid and gently warm; when solution has been effected, add the lard and mix.—Br.

As in the case of aconitine ointment, the alkaloid is here held in solution in an excess of oleic acid, and the name ointment of atropine oleate appears more appropriate. The ointment contains 2 per cent. of atropine.

Uses.—This preparation is preferable to belladonna ointment in superficial neuralgias and other local pains because a smaller quantity is necessary to produce results.

UNGUENTUM BELLADONNÆ, *U. S., Br.*—Belladonna Ointment.

Pommade belladonée, Fr. Cod.; *Belladonnasalbe*, G.

Preparation.—Extract of belladonna leaves, 10 Gm.; diluted alcohol, 5 Cc.; hydrous wool-fat, 20 Gm.; benzoinated lard, 65 Gm., to make about 100 Gm. Triturate the extract with the diluted alcohol until a smooth mixture is obtained; with this incorporate the hydrous wool-fat; then add the benzoinated lard and mixtho roughly.—U. S.

Using the above proportions in grains and multiplied by 5 will produce a little over a troyounce of the official belladonna ointment.

Liquid extract of belladonna, 2 fluidounces; benzoinated lard, 2¼ ounces. Evaporate the liquid extract of belladonna on a water-bath until it is reduced to ¼ ounce; add the lard and mix.—Br. This ointment should contain $\frac{6}{10}$ per cent. of the alkaloids of belladonna root.

Uses.—This ointment may be employed when the sedative effect of belladonna is desired in the treatment of painful conditions, especially of the rectum, urethra, and vagina.

Allied Ointment.—UNGUENTUM POPULEUM.—*Pommade de bourgeon de peuplier, Onguent populeum*, Fr. Cod. Digest the fresh leaves of belladonna, hyoscyamus, black nightshade, and poppy, of each 5 parts, in lard, 40 parts; when the moisture has completely evaporated, add poplar buds, 8 parts; digest for a day, express, and strain.

UNGUENTUM CANTHARIDIS, *Br.*—Ointment of Cantharides.

Unguentum cantharidum, P. G.; *Pommade épispastique*, Fr. Cod.; *Unguentum irritans, Unguentum ad fonticulos.—Spanischfliegensalbe*, G.

Preparation.—Cantharides, bruised, 1 ounce; benzoinated lard, 10 ounces. Melt the lard, add the cantharides, and digest at a temperature of about 48.9° C. (120° F.) for 12 hours. Strain through calico and press the residue gently; stir until cold.—Br.

Coarsely powdered cantharides, 3 parts; olive oil, 10 parts; digest for 10 hours in a corked flask on a water-bath, with repeated agitation, express and filter. To 12 parts of the filtrate add 8 parts of yellow wax.—P. G.

Uses.—The preparation of this ointment in the present British Pharmacopœia differs from that in the preceding one, which directed the flies to be digested in olive oil. It is not powerful enough to be employed as a vesicant, but is intended to prolong the effect of a previously applied blister, or to act as a rubefacient upon sound skin when blistering is not desired.

UNGUENTUM CAPSICI, *Br.*—Capsicum Ointment.

Pommade de piment des jardins, Fr.; *Spanisch-Pfeffersalbe*, G.

Preparation.—Capsicum fruit, bruised, 120 grains; spermaceti, 60 grains; olive oil, 1 ounce. Digest on a water-bath for 1 hour, occasionally stirring; then strain and set aside to cool without stirring.—Br.

Uses.—Capsicum ointment may be used as a counterirritant in place of a mustard poultice or capsicum plaster.

UNGUENTUM CHRYSAROBINI, *U. S., Br.*—Chrysarobin Ointment.

Pommade de chrysarobine, Fr.; *Chrysarobinsalbe*, G.

Preparation.—Chrysarobin, 6 Gm.; benzoinated lard, 95 Gm., to make about 100 Gm. Triturate the chrysarobin with the benzoinated lard, previously melted, and heat the mixture on a water-bath, with occasional stirring, for 20 minutes; then strain and stir until it congeals.—U. S.

To make 1 troyounce of the ointment use 30 grains of chrysarobin and 460 grains of benzoinated lard.

The British Pharmacopœia directs 20 grains of chrysarobin to be triturated with 480 grains of benzoinated lard, previously melted by heat; the heat is to be continued until the chrysarobin is dissolved, and the solution then stirred until cold.

In our experience none of the chrysarobin to be found on the market is perfectly soluble in melted lard, nor in boiling chloroform. It is, therefore, necessary to strain the mixture before stirring. The amount of insoluble matter has been found to be about 20 or 25 per cent.

Uses.—The uses for this ointment are discussed under CHRYSAROBINUM (which see).

UNGUENTUM COCAINÆ, *Br.*—Cocaine Ointment.

Pommade d'oléate de cocaine, Fr.; *Cocainoleatsalbe*, G.

Preparation.—Cocaine, 20 grains; oleic acid, 80 grains; lard, 400 grains. Rub the cocaine with the oleic acid, and gently warm until dissolved; add the lard and mix.—Br.

This ointment is practically an ointment of cocaine oleate and contains 5 per cent. of the alkaloid in combination.

Uses.—This ointment may be employed as a local anæsthetic over inflamed nerves and in painful conditions of the rectum, urethra, nose, and eye.

UNGUENTUM CONII, *Br.*—Conium Ointment.

Pommade de grande ciguë, Fr.; *Schirlingsalbe*, G.

Preparation.—Juice of conium, 2 fluidounces; hydrous wool-fat, ¾ ounce. Evaporate the juice of conium on a water-bath to ½ its volume, at a temperature not exceeding 60 C. (140 F.); add the hydrous wool-fat and mix by trituration.—Br.

Uses.—The applications of conium in ointment are described on p. 485.

UNGUENTUM CREOSOTI, *Br.*—Ointment of Creosote.

Pommade crêosotée, Fr.; *Kreosotsalbe*, G.

Preparation.—Creosote, 1 ounce; hard paraffin, 4 ounces; soft paraffin, 5 ounces. Add the creosote to the paraffins previously melted together, and stir until cold.—Br.

Uses.—Creosote ointment is stimulant and antiseptic, and is used as an application to chilblains, sluggish ulcers, especially those with fungous granulations, and to various cutaneous eruptions as eczema, sycosis, prurigo, etc.

UNGUENTUM DIACHYLON, *U. S., P. G.*—Diachylon Ointment.

Unguentum plumbi Hebræ.—Hebra's lead ointment, E.; *Onguent diachylon*, Fr.; *Bleipflastersalbe, Diachylonsalbe*, G.

Preparation.—Lead plaster, 50 Gm.; oil of lavender flowers, 1 Gm.; olive oil, 49 Gm. Melt the lead plaster by applying a gentle heat, add the olive oil, and mix thoroughly; then allow the mixture to cool, add the oil of lavender flowers, and stir the ointment until it congeals. It should be prepared extemporaneously.—U. S.

To make 1 troyounce of the ointment, use 240 grains of lead plaster, 5 drops of oil of lavender flowers, and 235 grains of olive oil.

The German Pharmacopœia directs that equal weights of lead plaster and olive oil be melted together and the mixture then stirred until cold.

Uses.—Following the recommendation of Hebra, diachylon ointment is largely employed in eczema, and to some extent in fetid or profuse sweating of the feet and hands.

UNGUENTUM EUCALYPTI, *Br.*—Eucalyptus Ointment.

Pommade d'eucalypte, Fr.; *Eukalyptussalbe*, G.

Preparation.—Oil of eucalyptus, 1 ounce; hard paraffin, 4 ounces; white soft paraffin, 5 ounces. Melt the hard and soft paraffins together; add the oil of eucalyptus and stir until cold.—Br.

Uses.—Eucalyptus ointment is sometimes applied to slugglish skin diseases and ulcers.

UNGUENTUM GALLÆ, *U. S., Br.*—Nutgall Ointment.

Gall ointment, E.; *Pommade de noix de galle*, Fr.; *Galläpfelsalbe*, G.

Preparation.—Nutgall, in No. 80 powder, 20 Gm.; ointment, 80 Gm.; to make 100 Gm. Rub the nutgall with the ointment, gradually added, until they are thoroughly mixed.—U. S.

Each troyounce of nutgall ointment contains 96 grains of nutgall and 384 grains of ointment; the nutgall is preferably passed through a bolting cloth before adding the lard.

The British Pharmacopœia directs that 1 ounce of very finely powdered nutgall be mixed with 4 ounces of benzoinated lard.

Uses.—Ointment of nutgall is used like ointment of Tannic Acid (which see).

UNGUENTUM GALLÆ CUM OPIO, *Br.*—Ointment of Galls and Opium.

Preparation.—Take of ointment of galls 925 grains; opium, in powder, 75 grains. Mix thoroughly.—Br.

Uses.—This ointment is considered of especial value in painful hemorrhoids.

UNGUENTUM HAMAMELIDIS, *Br.*—Hamamelis Ointment.

Pommade de hamamélis, Fr.; *Hamamelissalbe*, G.

Preparation.—Liquid extract of hamamelis, ½ fluidounce; hydrous wool-fat, 2½ ounces. Mix.—Br.

Uses.—This ointment is nearly if not quite devoid of active medicinal virtue. It may be used in hemorrhoids.

UNGUENTUM HYDRARGYRI, *U. S., Br.*—Mercurial Ointment.

Pommade mercurielle à parties égales, Fr. Cod.; *Unguentum mercuriale, Unguentum neapolitanicum.— Onguent napolitain, Onguent mercuriel double*, Fr.: *Quecksilbersalbe*, G.

Preparation.—Mercury, 500 Gm.; oleate of mercury, 20 Gm.; prepared suet, 230 Gm.; benzoinated lard, 250 Gm., to make 1000 Gm. Triturate the oleate of mercury in a warm mortar, add the mercury gradually by means of a pipet, and when the globules are completely divided and distributed, set it aside for about 15 minutes. Melt the lard and suet, allow the mixture to partially cool, and add about 25 Gm. of it to the mercurial mixture, and continue the trituration until globules are no longer visible under a lens magnifying 10 diameters. Then add the remainder of the lard and suet and mix thoroughly.

Assay of Mercurial Ointment.—Weigh 10 Gm. of mercurial ointment in a tared dish, melt it, then remove it from the fire and add 50 Cc. of warm petroleum benzin. Stir the mixture well, allow the mercury to settle completely, and decant the petroleum benzin. Wash the residue with successive portions of 10 Cc. each of warm petroleum benzin until it is entirely free from fatty matter, carefully retain all of the separated mercury in the dish, and allow all traces of the benzin to evaporate. Add to the residue 10 Cc. of diluted hydrochloric acid, heat it gently, and stir with a glass rod until the mercury collects in a large globule. Pour off the acid, warm the mercury with a little distilled water, dry the globule on bibulous paper, and weigh. The mercury should weigh not less than 4.9 Gm.—U. S.

Each troyounce of mercurial ointment contains 240 grains of pure mercury, 120 grains of lard, 115 grains of suet, and 5 grains of mercuric oleate.

The British Pharmacopœia directs that 1 pound each of mercury and lard be triturated together with 1 ounce of prepared suet until metallic globules are no longer visible. The ointment thus obtained is of nearly the same strength as the above, containing 1 part of mercury in $2\frac{1}{16}$ parts of finished product.

The French Codex directs that 500 Gm. of mercury be uniformly mixed with an equal weight of benzoinated lard. The extinguishment of the mercury by this method is a very tedious operation.

Uses.—Ointment of mercury is used in syphilis for the purpose of influencing the general system, either alone where mercury is not well borne by the stomach, or in combination with the internal administration of the medicine when it is desired to secure a rapid, powerful mercurial effect. In these cases it should be thoroughly rubbed into the skin of various parts of the body successively, as the axillæ, groins, abdomen, etc. If applied to the same area too often it is apt to cause decided irritation of the skin. This treatment is usually instituted by two inunctions a day of 1 drachm (4 Gm.) each of the ointment, the quantity to be increased if necessary to produce the desired effect, or diminished if symptoms of mercurialism appear. If the patient be able he should apply the ointment himself; if not, the hands of the attendant who makes the application should be protected by rubber gloves. In infantile syphilis the ointment may be applied as above directed, or spread upon a flannel binder kept constantly in position around the body. In addition to this employment of mercurial ointment, it is useful to reduce inflammatory enlargements, especially of glandular tissue, whether due to syphilis or other inflammatory processes. It has been highly recommended as an application to the papules of small-pox upon the face, to prevent their maturing and forming unsightly scars. Subacute and chronic arthritis from any cause is sometimes benefited by wrapping the joint in cloths spread with the ointment. Its use in erysipelas is of doubtful value. It will destroy pediculi and other parasites that infest the region of the genitalia, but, while efficacious, its use for this purpose is obnoxious to many individuals, and can be successfully supplanted by almost any fixed or volatile oil.

UNGUENTUM HYDRARGYRI AMMONIATI, *U. S., Br.*—Ointment of Ammoniated Mercury.

Unguentum hydrargyri album, P. G.—*Ointment of white precipitate*, E.; *Pommade de mercure précipité blanc*, Fr.; *Weisse Quecksilbersalbe*, G.

Preparation.—Ammoniated mercury, in a very fine powder, 10 Gm.; white petrolatum, 50 Gm.; hydrous wool-fat, 40 Gm., to make 100 Gm. Rub the ammoniated

mercury with an equal weight of melted white petrolatum, then add the remainder of the melted white petrolatum, mix thoroughly with the hydrous wool-fat, and stir the mixture until it congeals.—U. S.

To make 1 troyounce of the ointment, use 48 grains of ammoniated mercury, 240 grains of white petrolatum, and 192 grains of hydrous wool-fat.

Both the British and German Pharmacopœias direct white precipitate ointment to be made with paraffin ointment in the proportion of 1 part of ammoniated mercury to 9 parts of the ointment.

Uses.—Ointment of ammoniated mercury is used as a stimulant application in sluggish cutaneous affections, as psoriasis, indurated eczema, and in those of parasitic origin, as ringworm and petyriasis versicolor. It is sometimes applied to tubercular syphilitic eruptions.

UNGUENTUM HYDRARGYRI COMPOSITUM, *Br.*—Compound Ointment of Mercury.

Pommade mercurielle composée, Fr.; *Kampher-Quecksilbersalbe*, G.

Preparation.—Take of ointment of mercury 10 ounces; yellow wax, olive oil, each 6 ounces; camphor, 3 ounces. Melt the wax with a gentle heat, and add the oil; then, when the mixture is nearly cold, add the camphor in powder and the ointment of mercury, and mix the whole thoroughly together.—Br.

The ointment has a greenish tint, and is softened by the camphor.

Uses.—The addition of camphor to this formula increases the absorption of the mercury, but is apt to produce irritation of the skin if the ointment is used by inunction to obtain the constitutional effect of mercury.

UNGUENTUM HYDRARGYRI DILUTUM, *U. S.*—Blue Ointment.

Pommade mercurielle faible, Fr. Cod.; *Unguentum hydrargyri cinereum*, P. G.; *Unguentum hydrargyri mite.—Onguent mercuriel simple, Onguent gris*, Fr.; *Graue Quecksilbersalbe*, G.

Preparation.—Mercurial ointment, 670 Gm.; petrolatum, 330 Gm. Mix them thoroughly.—U. S.

Other pharmacopœias direct: Mercury, 100 parts; anhydrous wool-fat, 15 parts; olive oil, 3 parts; lard, 112 parts; suet, 70 parts.—P. G. Mercurial ointment, 100 Gm., benzoinated lard, 300 Gm.—Fr. Cod.

Blue ointment is identical in mercury strength with the preparation formerly known as mild mercurial ointment. The different pharmacopœias prescribe the same strength, namely, 33⅓ per cent. of metallic mercury, with exception of the French Codex, which directs only 12½ per cent.

Uses.—The uses of blue ointment do not differ from those of the stronger mercurial ointment.

UNGUENTUM HYDRARGYRI IODIDI RUBRI, *Br.*—Ointment of Red Iodide of Mercury.

Pommade d'iodure mercurique, Fr.; *Jodquecksilbersalbe*, G.

Preparation.—Take of mercuric iodide, in fine powder, 20 grains; benzoinated lard, 480 grains. Mix thoroughly.—Br.

Uses.—This ointment is used to stimulate indolent syphilitic and scrofulous ulcers, and to resolve tuberculous adenitis. A similar preparation is employed in India for the cure of goitre, by rubbing a quantity of the ointment over the tumor and exposing the patient for several hours to the sun's rays.

UNGUENTUM HYDRARGYRI NITRATIS, *U. S., Br.*—Ointment of Mercuric Nitrate.

Pommade citrine, Fr. Cod.; *Unguentum hydrargyri citrinum, Unguentum citrinum.—Citrine ointment*, E.; *Onguent citrin*, Fr.; *Quecksilbernitratsalbe*, G.

Preparation.—Mercury, 70 Gm.; nitric acid, 175 Gm.; lard, free from water, 760 Gm. To make about 1000 Gm. Heat the lard in a capacious glass or porcelain vessel

to a temperature of 105 C. (221 F.), then withdraw the heat and gradually add 70 Gm. of nitric acid. When the reaction moderates, reapply the heat until effervescence ceases, and allow the mixture to cool to about 40° C. (104 F.). Having dissolved the mercury in the remainder of the nitric acid, with the aid of sufficient heat to prevent the solution from crystallizing, add this solution to the lard mixture. When the mass begins to stiffen, stir it thoroughly with a wooden spatula until it is of bright citrine color. Contact with metallic utensils should be avoided.—U. S.

To make 4 avoirdupois ounces of citrine ointment, use 123 grains of mercury, 306 grains of nitric acid, and 1330 grains of lard: 123 grains of the acid are used for treatment of the lard, and the remainder for the solution of the mercury. It is important that the nitric acid should be of official strength, and that the oxidation of the fat be completed before the addition of the mercurial solution, so as to avoid reduction of the mercurial salt and consequent discoloration. When carefully made the ointment is of a bright lemon-yellow color and keeps well, gradually, however, darkening somewhat in color.

The directions of the British Pharmacopœia are entirely different: 1 ounce of mercury is dissolved in 3 fluidounces of nitric acid without the aid of heat, forming a solution of mercurous nitrate; 4 ounces of lard and 7 ounces of olive oil are then heated together on a sand-bath to a temperature of 143.3° C. (290° F.); the cold mercurial solution is then added very gradually, stirring constantly to promote liberation of fumes. After frothing has ceased, the mixture, which should have a temperature of not less than 93.3° C. (200° F.), must be stirred until it is cold.

On mixing melted fats with a solution of mercuric nitrate containing free nitric acid, a very complicated reaction takes place, resulting, on the one hand, in the oxidation of the fat and the evolution of nitric oxide (nitrogen dioxide) and nitrogen tetroxide, and, on the other hand, in the conversion by the latter of the olein contained in the fat into solid elaidin. The products of oxidation of the fat contain various volatile fatty acids, but must necessarily vary with the nature of the fat, the amount of free nitric acid, and the degree of the heat. Should the nitric acid be insufficient in quantity or the temperature rise to too high a degree, the oxidation is effected in part at the expense of the mercuric nitrate, which is thereby reduced to mercurous salt. In our experience an equally good and permanent ointment is obtained by heating both the mercuric solution and the fat to about 70° C. (158° F.) before mixing them; and even a lower degree of heat, about 50° C. (122 F.), will produce good results if the reaction is completed before the ointment is permitted to cool. All difficulties are, however, overcome by following the process adopted by the U. S. P. The French Codex directs 1 part of mercury and 2 parts of nitric acid to 20 parts of fat composed of equal weights of lard and olive oil; this salve is firm, and is sold in the form of square cakes.

Citrine ointment should be prepared in glass or porcelain vessels, and should not be brought into contact with iron or other metal.

Uses.—Ointment of mercuric nitrate is a very stimulating application, useful in chronic and parasitic skin diseases, as psoriasis, indurated eczema, ringworm of the scalp, pityriasis; in indolent syphilitic and scrofulous ulcers, and in fissures of the lips and anus. It generally requires dilution with lard unless a very active effect is desired. It may occasion salivation if used too freely.

Allied Ointment.—Unguentum Hydrargyri Nitratis Dilutum, Br. Mix nitrate-of-mercury ointment 1 ounce with soft paraffin 4 ounces.

UNGUENTUM HYDRARGYRI OLEATIS, *Br.*—Mercuric Oleate Ointment.

Pommade d'oléate mercurique, Fr.; *Quecksilberoleatsalbe*, G.

Preparation.—Mercuric oleate, 1 ounce; benzoinated lard, 3 ounces. Mix.—Br.

Since the official mercuric oleate of the British Pharmacopœia is the normal oleate, representing about 26.23 per cent. of mercury, this ointment may be considered as a 25 per cent. ointment of mercuric oleate.

Uses.—The properties of this preparation closely resemble those of mercurial ointment. It is considered to be more readily absorbed by the skin and to more rapidly produce constitutional effects.

UNGUENTUM HYDRARGYRI OXIDI FLAVI, *U. S.*—Ointment of Yellow Mercuric Oxide.

Pommade d'oxyde jaune de mercure, Fr.; *Gelbe Quecksilberoxydsalbe*, G.

Preparation.—Yellow mercuric oxide, in very fine powder, 10 Gm.; distilled water, 10 Gm.; hydrous wool-fat, 40 Gm.; petrolatum, 40 Gm.; to make 100 Gm. Triturate the yellow mercuric oxide with the water until the mixture is perfectly smooth and absolutely free from gritty particles, then add the petrolatum and the hydrous wool-fat in divided portions, and incorporate them thoroughly, avoiding contact with metallic utensils.—U. S.

To prepare 1 troyounce of the ointment, 48 grains of yellow oxide of mercury should be triturated with an equal weight of distilled water until perfectly smooth, and then incorporated with 192 grains each of petrolatum and hydrous wool-fat in divided portions.

Other pharmacopœias direct: Yellow mercuric oxide, 10 grains; soft paraffin (yellow), 490 grains.—Br. Yellow oxide of mercury, 1 Gm.; vaseline, 15 Gm.—Fr. Cod.

The object of triturating the oxide with distilled water is to insure reduction to an impalpably fine powder, and the hydrous wool-fat facilitates the incorporation of the petrolatum in the presence of the water. Only glass, porcelain, and horn utensils should be used, and the ointment should be protected against direct sunlight and high temperatures.

Uses.—This ointment is better than that of the red oxide in the treatment of blepharitis and conjunctivitis, and to abort styes, because the oxide is in a finer state of division, and is less apt to irritate the conjunctiva. It is too strong for ordinary use, and should be diluted from 5 to 10 times.

UNGUENTUM HYDRARGYRI OXIDI RUBRI, *U. S., Br.*—Ointment of Red Mercuric Oxide.

Unguentum hydrargyri rubrum, P. G.; *Pommade d'oxyde rouge de mercure*, Fr. Cod.; *Unguentum precipitati rubri.—Pommade de Lyon, Baume ophthalmique rouge*, Fr.; *Rothe Quecksilbersalbe*, G.

Preparation.—Red mercuric oxide, in very fine powder, 10 Gm.; distilled water, 10 Gm.; hydrous wool-fat, 40 Gm.; petrolatum, 40 Gm.; to make 100 Gm. Triturate the red mercuric oxide with the water until the mixture is perfectly smooth and absolutely free from gritty particles, then add the petrolatum and the hydrous wool-fat in divided portions, and incorporate them thoroughly. Contact with metallic utensils should be avoided.—U. S.

To prepare 1 troyounce of the ointment, 48 grains of red mercuric oxide should be triturated with an equal weight of distilled water until perfectly smooth, and then incorporated with 192 grains each of petrolatum and hydrous wool-fat in divided portions.

Other pharmacopœias direct: Red mercuric oxide, ¼ ounce; paraffin ointment (yellow), 2¼ ounces.—Br. Red oxide of mercury, 1 Gm.; vaseline, 15 Gm.—Fr. Cod. Red oxide of mercury, 1 part; paraffin ointment, 9 parts.—P. G.

The comments made under the previous preparation apply also to this ointment.

Uses.—This ointment is applied as a stimulant to sluggish ulcers, particularly those of syphilitic origin. If spread over too large a surface, enough mercury may be absorbed to produce characteristic effects of the drug upon the system. In the treatment of chronic inflammations of the eyelids it has been supplanted by the ointment of the yellow oxide.

UNGUENTUM HYDRARGYRI SUBCHLORIDI, *Br.*—Mercurous Chloride Ointment.

Unguentum calomelanos.—Calomel ointment, E.; *Pommade de chlorure mercureux, Pommade de calomel*, Fr.; *Quecksilberchlorürsalbe*, G.

Preparation.—Take of mercurous chloride ¼ ounce; benzoinated lard, 2¼ ounces. Mix thoroughly.—Br.

Calomel, 1 part, benzoinated lard, 9 parts.—Fr. Cod. This ointment, being known in France also as *pommade au précipité blanc*, should not be confounded with the ointment of ammoniated mercury.

Uses.—Calomel ointment is the least irritating of the mercurial preparations intended for external use. It is used for the same purpose as the others, but is less efficacious.

UNGUENTUM IODI, *U. S.*, *Br.*—Iodine Ointment.

Unguentum iodinii.—Pommade d'iode, Fr.; *Jodsalbe*, G.

Preparation.—Iodine, 4 Gm.; potassium iodide, 4 Gm.; glycerin, 12 Gm.; benzoinated lard, 80 Gm., to make 100 Gm. Triturate the iodine and potassium iodide in a glass mortar with the glycerin until dissolved, then gradually incorporate the benzoinated lard and mix thoroughly, avoiding the use of a metallic spatula. This ointment should be freshly made when required.—U. S.

Each troyounce of iodine ointment contains 19¼ grains each of iodine and potassium iodide, 58 grains of glycerin, and 383½ grains of benzoinated lard.

The directions of the British Pharmacopœia are identical with the above, except that plain lard instead of the benzoinated is ordered.

Uses.—Iodine ointment is employed to reduce the swelling occurring in subacute or chronic inflammation of glandular tissues, as of the tonsils, thyroid and lymphatic glands. It sometimes promotes the absorption of the inflammatory effusions of arthritis, pericarditis and pleurisy, and it enjoys quite a reputation as a remedy in chilblains.

UNGUENTUM IODOFORMI, *U. S.*, *Br.*—Iodoform Ointment.

Pommade d'iodoforme, Fr.; *Jodoformsalbe*, G.

Preparation.—Iodoform, in very fine powder, 10 Gm.; lard, 90 Gm., to make 100 Gm. Rub the iodoform with the lard, gradually added, until they are thoroughly mixed.—U. S.

Each troyounce of the ointment contains 48 grains of iodoform and 432 grains of lard. An impalpable powder of iodoform is readily obtained by trituration with alcohol.

Iodoform, ¼ ounce; paraffin ointment (yellow), 2¼ avoirdupois ounces.—Br.

The ointment should be perfectly smooth and free from grittiness; it has a light-yellow color and the peculiar odor of iodoform.

Uses.—For the applications of this ointment see IODOFORMUM.

UNGUENTUM PARAFFINI, *Br.*, *P. G.*—Paraffin Ointment.

Pommade de paraffin, Fr.; *Paraffinsalbe*, G.

Preparation.—Hard paraffin, 3 ounces; soft paraffin, 7 ounces. Melt together in a shallow evaporating dish; as the liquid cools triturate constantly until, when cold, a uniform plastic ointment is produced.—Br.

The German Pharmacopœia directs that 1 part of hard paraffin and 4 parts of liquid paraffin be melted together. The resulting ointment is white, and should melt between 40° and 50° C. (104° and 122° F.).

The two ointments differ from each other merely in degree of firmness, that of the Br. P. having the higher melting point.

Uses.—This is a simple, emollient ointment resembling petrolatum in its properties.

UNGUENTUM PHENOLIS, *U. S.*—Ointment of Phenol.

Unguentum acidi carbolici, Br., U. S., 1890.—*Phenol ointment, Ointment of carbolic acid*, E.; *Pommade de phénol, Pommade phéniquée*, Fr.; *Phenolsalbe, Karbolsalbe*, G.

Preparation.—Phenol, 3 Gm.; white petrolatum, 97 Gm. To the melted white petrolatum add the phenol, and stir the mixture until it begins to congeal.—U. S.

To prepare 1 troyounce of phenol ointment, add 14½ grains of phenol to 465½ grains of white petrolatum previously melted.

The British Pharmacopœia directs that ½ ounce of phenol be dissolved in 1½ ounces of glycerin and the solution mixed with 10½ ounces of white paraffin ointment.

The present official ointment of carbolic acid is only ⅗ as strong as that of 1890, which contained 5 per cent. of phenol. The British ointment contains 4 per cent. of phenol.

Uses.—This is an antiseptic preparation largely employed in domestic practice as an application to burns, superficial wounds, sores, etc.

UNGUENTUM PICIS LIQUIDÆ, *U. S., Br.*—Tar Ointment.

Pommade de goudron, Fr. Cod.; *Theersalbe*, G.

Preparation.—Tar, 500 Gm.; yellow wax, 125 Gm.; lard, 375 Gm.; to make 1000 Gm. Melt together the yellow wax and the lard at a moderate heat. Then incorporate the tar, previously warmed, strain the mixture through muslin, and stir the ointment until it is cool.—U. S.

Each troyounce of tar ointment contains 240 grains of tar, 60 grains of yellow wax, and 180 grains of lard.

Tar, 5 ounces; yellow wax, 2 ounces; melt the wax with a gentle heat, add the tar, and stir the mixture briskly while it cools.—Br. Tar, 1 part; lard, 9 parts. Mix.—Fr. Cod.

Uses.—Tar ointment is largely employed as an application in psoriasis and other scaly and sluggish eruptions, and in eczema rubrum after the liquid secretion has ceased. In ringworm, especially of the scalp, its use is frequently attended by happy results.

UNGUENTUM PLUMBI ACETATIS.—Lead Acetate Ointment.

Pommade d'acétate de plomb, Fr.; *Bleizuckersalbe*, G.

Preparation.—Lead acetate, in fine powder, 20 grains; paraffin ointment (white), 480 grains. Mix.—Br.

Uses.—The uses of this ointment are similar to those of the CERATUM PLUMBI SUBACETATIS, U. S. P.

UNGUENTUM PLUMBI CARBONATIS, *Br.*—Lead Carbonate Ointment.

Unguentum cerussæ, P. G.; *Ointment of white lead*, E.; *Pomma de carbonate de plomb, Pommade de céruse, Onguent blanc de Rhazès*, Fr.; *Bleiweissalbe*, G.

Preparation.—Lead carbonate, in fine powder, ½ ounce; paraffin ointment (white), 2½ ounces. Mix.—Br.

The ointment of the German Pharmacopœia is 3 times as strong as that of the British, but is made with the same vehicle. The French Codex directs 10 Gm. of lead carbonate to be mixed with 50 Gm. of benzoinated lard.

Uses.—This ointment is particularly serviceable as a soothing application to recent superficial burns. It may also be applied to wounds and inflamed surfaces.

Allied Ointment.—UNGUENTUM CERUSSÆ CAMPHORATUM.—*Camphorated Ointment of Lead Carbonate*, E.; *Kampherhaltige Bleiweissalbe*, G.

This ointment is prepared by incorporating 1 part of very finely powdered camphor with 19 parts of ointment of lead carbonate.

UNGUENTUM PLUMBI IODIDI, *Br.*—Lead Iodide Ointment.

Pommade d'iodure de plomb, Fr.; *Jodbleisalbe*, G.

Preparation.—Lead iodide, in fine powder, ½ ounce; paraffin ointment (yellow), 2½ ounces. Mix.—Br.

The French Codex directs lead iodide, 10 Gm., to be mixed with 90 Gm. of benzoinated lard.

Uses.—The uses of this ointment are considered under PLUMBI IODIDUM (which see).

UNGUENTUM PLUMBI TANNATIS.—Ointment of Lead Tannate.

Unguentum plumbi tannici, P. G.; *Pommade de tannate de plomb*, Fr.; *Gerbsäure-Bleisalbe*, G.

Preparation.—Tannic acid, 1 part; solution of lead subacetate, 2 parts; lard, 17 parts. Add the tannic acid to the solution of lead subacetate and triturate until a perfectly smooth magma results, which is then incorporated with the lard. The ointment should be prepared fresh when called for.—P. G.

Uses.—This ointment may be used with benefit in hemorrhoids and other conditions in which a local astringent effect is desired.

UNGUENTUM POTASSII IODIDI, *U. S., Br.*—Ointment of Potassium Iodide.

Unguentum kalii iodati, P. G.; *Pommade d'iodure de potassium*, Fr. Cod.; *Jodkaliumsalbe*, G.

Preparation.—Potassium iodide, 10 Gm.; potassium carbonate, 0.6 Gm.; water, 10 Gm.; benzoinated lard, 80 Gm.; to make about 100 Gm. Dissolve the potassium iodide and potassium carbonate in the water by trituration, then gradually add the benzoinated lard and incorporate thoroughly. This ointment should be prepared extemporaneously.—U. S.

To prepare 1 troyounce of the ointment, dissolve 48 grains of potassium iodide and 3 grains of potassium carbonate in 50 minims of water, and gradually incorporate the solution with 381 grains of benzoinated lard.

Other pharmacopœias direct: Potassium iodide, 50 grains; potassium carbonate, 3 grains; distilled water, 47 grains; benzoinated lard, 400 grains.—Br. Potassium iodide, 10 Gm.; water, 10 Gm.; benzoinated lard, 80 Gm.—Fr. Cod. Potassium iodide, 20 parts; sodium thiosulphate, ¼ part; water, 15 parts; lard, 165 parts.—P. G.

The object of adding potassium carbonate or sodium thiosulphate to the ointment is to prevent discoloration of the same by free iodine.

Uses.—It is proposed to employ this preparation like ointment of iodine to resolve glandular inflammations, but to our mind it is greatly inferior to the latter for this purpose.

UNGUENTUM ROSMARINI COMPOSITUM, *P. G.*—Compound Rosemary Ointment.

Onguent de romarin composé, Fr.; *Rosmarinsalbe*, G.

Preparation.—Suet, 8 parts; yellow wax, 2 parts; lard, 16 parts; expressed oil of nutmeg, 2 parts; oil of rosemary, 1 part; oil of juniper, 1 part. Melt the suet, wax, lard, and expressed oil of nutmeg together, strain, and stir until cool; then while still soft incorporate the oils of rosemary and juniper.—P. G.

Uses.—An aromatic, emollient ointment which may be applied to slight inflammations of the skin.

UNGUENTUM STAPHISAGRIÆ, *Br.*—Stavesacre Ointment.

Onguent de staphisaigre, Fr.; *Stephanskörnersalbe*, G.

Preparation.—Stavesacre seeds, 2 ounces; yellow wax, 1 ounce; benzoinated lard, 8½ ounces. Crush the stavesacre seeds and digest with the benzoinated lard for 2 hours on a water-bath; strain and express; add the wax and heat gently until the wax is melted, then stir until cold.—Br.

Uses.—Stavesacre ointment is useful to destroy pediculi or other vermin that might infest the body.

UNGUENTUM STRAMONII, *U. S.*—Stramonium Ointment.

Pommade de stramoine, Fr.; *Stechapfelsalbe*, G.

Preparation.—Extract of stramonium, 10 Gm.; diluted alcohol, 5 Gm.; hydrous wool-fat, 20 Gm.; benzoinated lard, 65 Gm.; to make 100 Gm. Triturate the extract with the diluted alcohol until a smooth mixture is obtained; with this incorporate the hydrous wool-fat, then add the benzoinated lard and mix thoroughly.—U. S.

To make 1 troyounce of stramonium ointment, rub 48 grains of extract of stramonium with 30 minims of diluted alcohol into a smooth paste, and with this incorporate 96 grains of hydrous wool-fat; then add 312 grains of benzoinated lard and mix thoroughly.

The present official stramonium ointment differs from that of 1890 in being made with extract of stramonium leaves, and it will therefore have a deep-green color. Stramonium seed and the extract made therefrom are no longer recognized.

Uses.—Stramonium ointment may be used like belladonna ointment as a local anodyne in case of hemorrhoids, cancer of the rectum, irritable ulcers and fissures, etc.

UNGUENTUM SULPHURIS, *U. S.*, *Br.*—Sulphur Ointment.

Pommade soufrée, Fr. Cod.; *Pomatum sulfuratum; Unguentum sulfuratum simplex. Schwefelsalbe*, G.

Preparation.—Washed sulphur, 150 Gm.; benzoinated lard, 850 Gm.; to make 1000 Gm. Rub the sulphur, with the benzoinated lard gradually added, until they are thoroughly mixed.—U. S.

Each troyounce of the ointment contains 72 grains of washed sulphur and 408 grains of benzoinated lard.

Sublimed sulphur, 1 ounce; benzoinated lard, 4 ounces.—Br. Washed sulphur, 10 parts; almond oil, 10 parts; benzoinated lard, 80 parts.—Fr. Cod.

Uses.—Sulphur ointment is a specific for scabies, and is useful also in certain chronic skin diseases. For its mode of application in scabies see SULPHUR SUBLIMATUM.

Allied Ointments.—UNGUENTUM SULPHURIS ALKALINUM. *Alkaline sulphur ointment*, E.; *Helmerich's Salbe*, G.—Washed sulphur, 20 parts; potassium carbonate, 10 parts; water, 5 parts; benzoinated lard, 65 parts; to make 100 parts. Rub the sulphur with the potassium carbonate and the water, gradually add the benzoinated lard, and mix thoroughly.

UNGUENTUM SULPHURIS IODIDI, *Br.*—Ointment of Iodide of Sulphur.

Pommade d'iodure de soufre, Fr.; *Jodschwefelsalbe*, G.

Preparation.—Sulphur iodide, 20 grains; glycerin, 20 grains; benzoinated lard, 460 grains. Triturate the sulphur iodide and glycerin in a slightly warmed mortar to a smooth paste, then add the lard gradually, and stir until the ointment is cold.—Br.

Uses.—This ointment may be applied with good results in some cases of chronic skin lesions, as psoriasis, lepra, acne, and in eczema and impetigo after the stage of secretion.

UNGUENTUM TEREBINTHINÆ, *P. G.*—Turpentine Ointment.

Onguent térébenthine, Fr.; *Terpentinsalbe*, G.

Preparation.—Turpentine, 1 part; yellow wax, 1 part; oil of turpentine, 1 part. Melt the turpentine and wax together, strain and cool, and while still soft incorporate the oil of turpentine.—P. G.

Uses.—The uses of this ointment resemble those of the CERATUM RESINÆ COMPOSITUM, U. S. P. (which see).

Allied Ointment.—UNGUENTUM DIGESTIVUM SIMPLEX.—*Onguent digestif simple*, Fr. Cod.—Venice turpentine, 40 Gm.; yolk of egg, 20 Gm.; olive oil, 10 Gm. Mix the yolk of egg and Venice turpentine in a mortar, and little by litle incorporate the olive oil.—Fr. Cod.

UNGUENTUM VERATRINÆ, *U. S.*, *Br.*—Veratrine Ointment.

Pommade de vératrine, Fr.; *Veratrinsalbe*, G.

Preparation.—Veratrine, 4 Gm.; expressed oil of almonds, 6 Gm.; benzoinated lard, 90 Gm., to make 100 Gm. Rub the veratrine with the expressed oil of almond, then gradually add the benzoinated lard, and mix thoroughly.—U. S.

To make 1 troyounce of the ointment, rub 20 grains of the veratrine with 30 grains of expressed oil of almond perfectly smooth, and gradually add 430 grains of benzoinated lard.

Veratrine, 10 grains; oleic acid, 40 grains; lard, 450 grains. Rub the veratrine with the oleic acid and gently warm the mixture until dissolved; then add the lard and mix.—Br.

The U. S. P. ointment is about twice as strong as the British, and, besides, the latter contains the veratrine in combination as oleate.

Uses.—The uses of this ointment are described under VERATRINA (which see).

UNGUENTUM ZINCI OLEATIS, *Br.*—Zinc Oleate Ointment.

Pommade d'oléate de zinc, Fr.; *Zinkoleatsalbe*, G.

Preparation.—Zinc sulphate, 2 ounces; hard soap, 4 ounces; boiling distilled water, white soft paraffin, of each a sufficient quantity. Dissolve the zinc sulphate in 4 fluidounces of the water, and the soap in 40 fluidounces of the water. Mix the solutions; collect the precipitated zinc oleate and wash with hot water until little or no reaction for sulphate is obtained; dry on a water-bath and mix with an equal weight of previously melted soft paraffin.—Br.

Since in the above operation normal zinc oleate is formed, the finished product constitutes a 50 per cent. ointment of the same. In order to secure a perfectly smooth ointment it will be found advantageous to melt the zinc oleate after drying, then to add the melted paraffin, and stir the mixture until cold.

Uses.—The properties of this preparation are similar to those of the ointment of zinc oxide.

UNGUENTUM ZINCI OXIDI, *U. S.*—Ointment of Zinc Oxide.

Unguentum zinci, Br., P. G.—*Zinc ointment*, E.; *Pommade d'oxyde de zinc*, Fr.; *Zinksalbe*, G.

Preparation.—Zinc oxide, in very fine powder, 200 Gm.; benzoinated lard, 800 Gm. Rub the zinc oxide, which must be free from gritty particles, with an equal weight of the melted benzoinated lard, and with this incorporate the remainder of the benzoinated lard previously melted; if necessary, strain the ointment while warm, and stir thoroughly until it congeals.—U. S.

To make 1 pound of zinc ointment, use 3 avoirdupois ounces and 88 grains of zinc oxide, and 12 avoirdupois ounces and 350 grains of benzoinated lard.

The British Pharmacopœia directs that 3 ounces of zinc oxide be mixed with 17 ounces of benzoinated lard. The German Pharmacopœia orders zinc oxide, 1 part; and lard, 9 parts.

It is important that the zinc oxide be in impalpably fine powder, and for this purpose it should be passed through a fine (No. 100) bolting-cloth sieve.

Uses.—This mildly astringent and stimulant ointment is extensively employed as a soothing, protective agent in superficial burns, ulcers, fissures of the nipples and anus, excoriations, and for the local eruptions of eczema, herpes, impetigo, and other skin lesions.

UNGUENTUM ZINCI STEARATIS, *U. S.*—Ointment of Zinc Stearate.

Pommade de stéarate de zinc, Fr.; *Zinkstearatsalbe*, G.

Preparation.—Zinc stearate, in fine powder, 50 Gm.; white petrolatum, 50 Gm. To the white petrolatum, melted on a water-bath, add the zinc stearate. Continue the heat until the mixture becomes smooth, then stir while cooling until it congeals.—U. S. This preparation represents a 50 per cent. ointment of zinc stearate, the latter salt being preferred by many to zinc oleate on account of its greater permanency.

Uses.—Ointment of zinc stearate is feebly antiseptic and astringent. The indications for its use are practically those for which the ointment of zinc oxide will be found of service.

URANIUM.—Uranium.

Urane, Fr.; *Uran*, G.

Symbol, U. Atomic weight, 236.7. Valence, 2 to 8.

History.—Uranium is one of the less abundant elements, occurring chiefly in the mineral known as pitchblende or uraninite, which is found in Bohemia, Saxony, Cornwall, Colorado, Utah, etc. Several other minerals, which are rarer than pitchblende, also contain uranium. Pitchblende is practically the only source of uranium salts on the market; it is a very complex mixture, containing, besides uranium oxide, U_3O_8, as chief constituent, smaller or larger quantities of oxides of many other metals, as lead, barium, bismuth, iron, zinc, radium, polonium, etc. Uranium compounds were first isolated by Klaproth in 1789 from pitchblende. For a long time the iron-gray crystal-

line uranous oxide, UO_2, was thought to be an element, and Péligot was the first to succeed in obtaining the metal in 1841 as a grayish-black powder, and in 1856 as a bright compact mass. Uranium is obtained as nitrate from pitchblende by treating the finely powdered mineral with concentrated nitric acid, and removing from the solution by various treatments the numerous other metals. The nitrate is the starting-point for the other compounds of uranium. When heated it is decomposed, leaving the trioxide, UO_3. If this be mixed with charcoal and heated to a high temperature in an atmosphere of chlorine, the tetrachloride, UCl_4, is formed. To obtain the metal, the chloride is reduced by sodium under a cover of molten sodium chloride, or, better, by igniting in a crucible a mixture of uranium oxide and aluminum powder wetted with one-third its volume of liquefied air.

Properties.—Uranium is a very heavy and very hard metal, with a color and lustre like that of nickel or iron, but black in a finely divided state. At white heat it burns in air with great brilliancy. It has the density 18.4, and dissolves in dilute acids with evolution of hydrogen. Marked characteristics of the element are its variable valence, and the fact that it has the highest atomic weight; also the fact that it is radio-active (see also RADIUM). Soluble uranium compounds are poisonous, and produce, especially when injected subcutaneously, even in small doses, symptoms of diabetes.

Chlorides.—Uranium forms three chlorides; the *trichloride*, UCl_3, a brownish-red mass obtained by reduction of UCl_4 with hydrogen, is unstable and oxidized by water; the *tetrachloride*, UCl_4, brilliant, dark-green crystals, soluble in water, and obtained as described above; the *pentachloride*, UCl_5, obtained in the same way as the tetrachloride and separated from it by its greater volatility, is a brown crystalline substance, decomposed in water into chlorine and the tetrachloride.

Oxides.—Four oxides are known. *Uranous oxide*, UO_2, is a gray or reddish-brown powder, obtained by reduction of the trioxide with hydrogen. *Urano-uranic oxide*, U_3O_8, is the last product of the action of oxygen on uranium or the other oxides when these are heated in the air. It also occurs naturally as the chief constituent of pitchblende. When it is dissolved in nitric acid, it is converted into uranyl nitrate, $UO_2(NO_3)_2$, which is a derivative of the higher oxide, UO_3. *Uranium trioxide*, UO_3, is a yellow powder obtained by heating the nitrate, which at higher heat loses oxygen and leaves the oxide, U_3O_8. *Uranium tetroxide*, UO_4, is known only in combination, in peruranic acid.

Action and Uses.—Uranium is not used medicinally. Its salts, some of which have been given in disease, are all powerful, corrosive poisons, producing in poisonous doses severe gastro-enteritis, retardation in the reduction of oxyhæmoglobin in the blood, degeneration of blood-vessels and the viscera, especially the kidney. The urine is increased in quantity and specific gravity and contains albumin and glucose, the last being perhaps the result of the lessened oxidation. Uranyl acetate has been recommended in coryza, being used either as a snuff after dilution with some inert powder, or in solution as a nasal douche. Uranyl nitrate has been used in diabetes in the dose of $\frac{1}{8}$ to $\frac{1}{4}$ grain (0.01–0.015 Gm.).

SALTS OF URANIUM.

Ammonium diuranate, $(NH_4)_2U_2O_7$, is also manufactured in large quantity. It is soluble in ammonium carbonate, which fact is utilized in analysis to separate uranium from other metals.

Sodium diuranate, $Na_2U_2O_7$, is a fine yellow powder, and is manufactured and sold under the name *uranium yellow*. It is precipitated when an excess of sodium hydroxide is added to a solution of uranyl nitrate. It is used to color glass, etc., light yellow; at the same time a brilliant greenish fluorescence is produced. Uranous salts produce a black color, and are used to paint porcelain ware.

Uranous salts are derived from quadrivalent uranium, and may be obtained by dissolving the metal, or the dioxide in acids, or by reduction of the uranyl salts. They are green and are oxidized in solution by the air. Not many salts of this order are known, the best-known one being the sulphate, $U(SO_4)_2.4H_2O$. With alkalies they precipitate brown uranous hydroxide, $U(OH)_4$.

Uranyl acetate, $UO_2(C_2H_3O_2)_2+2$ or $3H_2O$, may be obtained by heating anhydrous uranium nitrate to redness until all nitric acid has been dissipated, and then dissolving the residuary uranium oxide in 30 per cent. acetic acid. The resulting solution is evaporated and set aside to crystallize. If allowed to crystallize from dilute solutions, the salt will contain 3 molecules of water, but if crystallized from concentrated hot solutions it contains only 2. It occurs in rhombic crystals of yellow color, which are readily soluble in water. Should the salt contain basic uranyl acetate, a perfectly clear solution will result only after addition

of a little acetic acid. Solutions of uranyl acetate undergo decomposition when exposed to light, or if allowed to stand in a warm place for some time.

Uranyl nitrate, $UO_2(NO_3)_2 + 6H_2O$, is obtained from pitchblende, as already described. It crystallizes in large, greenish-yellow, fluorescent prisms, which are soluble in water and alcohol. It is used in quantitative analysis to titrate phosphates. Uranyl forms in phosphoric acid the salt $(UO_2)HPO_4$, or when ammonium salts are present the double salt, $(UO_2)NH_4PO_4$, both of which are insoluble in acetic acid, in which medium the titration is carried out. The end-point is shown by the intense brownish-red color given by the least excess of the uranium reagent with potassium ferrocyanide as indicator.

Uranyl salts are derived from the trioxide, UO_3, which has the peculiar property of acting like a base toward strong acids, and like an acid toward strong bases. The compounds with acids have a structure similar to that of the bismuthyl salts, in that the complex divalent group or radical, UO_2, called uranyl, takes the place of two hydrogen atoms of the acid; thus $UO_2(NO_3)_2$, $(UO_2)SO_4$, etc. They are regarded as derived from the yellow hydroxide, $UO_2(OH)_2$, as shown by the reaction $UO_2(OH)_2 + 2HNO_3 = UO_2(NO_3)_2 + 2H_2O$. Uranyl forms salts with nearly all organic acids, of which the oxalate is the most interesting. This is very sensitive to light, especially direct sunlight, in which it evolves carbon monoxide and carbon dioxide and forms a precipitate of uranyl hydroxide. Similar decompositions occur with other salts. When UO_3 or $UO_2(OH)_2$ acts as an acid toward strong bases, salts are formed of an acid, $H_2U_2O_7$, which may be called *diuranic acid*, as it is analogous in composition to dichromic acid, $H_2Cr_2O_7$.

Uranyl sulphate, $(UO_2)SO_4 + 3H_2O$, is obtained by decomposing the nitrate with sulphuric acid, as lemon-yellow needles. It forms a double salt with ammonium sulphate, $(UO_2)SO_4.(NH_4)_2SO_4 + 2H_2O$, which is difficultly soluble in water and crystallizes in yellow prisms. The corresponding potassium salt was used by Becquerel when he discovered the radio-activity of uranium (see under RADIUM).

UREA.—Urea.

Carbamide.—Urée, Fr.; *Harnstoff, Carbonylamid,* G.

Formula, $CH_4N_2O = CO(NH_2)_2$. Molecular weight, 59.65.

Origin.—Urea was discovered in urine by Rouelle (1773), and, in the impure condition in which he obtained it, designated as *extrait savonneux de l'urine.* Fourcroy and Vauquelin (1799) prepared it in the pure state. It has been found in the urine of mammals, more particularly in that of the Carnivora, in the urine of birds and other animals, and in many animal fluids. Human urine contains from 2 to 4 per cent. of urea. The transformation into urea of ammonium cyanate by evaporating its aqueous solution, as observed by Wöhler (1828), was the first instance in which an organic compound produced in the living organism was artificially formed. Urea has also been artificially prepared from other cyanogen compounds.

Preparation.—Urine is evaporated to a syrupy consistence, allowed to cool, and the residue mixed with an equal volume of nitric acid. The nitrate of urea, which crystallizes in scales and prisms, is purified by washing with cold water and by recrystallization, and is then decomposed by boiling with water and barium carbonate; the filtrate is evaporated and the residue exhausted with alcohol. Oxalic acid and calcium carbonate may be substituted in this process for nitric acid and barium carbonate.

Urea may be prepared by fusing an intimate mixture of 100 parts of dry potassium ferrocyanide and 37.5 parts of potassium carbonate, adding 187.5 parts of dry litharge to the cooled mass and again fusing for 10 to 15 minutes. The clear molten mass is poured upon sheet-iron, cooled, dissolved in about 200 Cc. of water, and the solution filtered direct into a concentrated aqueous solution containing 100 Gm. of ammonium sulphate, and then evaporating the mixture to a small volume whereby the ammonium cyanate formed undergoes transformation into its isomer urea. Potassium sulphate is first removed from the solution by crystallization, and the urea recovered from the concentrated mother liquor by extraction with alcohol and purified by recrystallization from alcohol. (Hager).

Properties.—Urea crystallizes in colorless and inodorous four-sided prisms, which have a cooling saline taste, and are permanent in dry air. It melts at 132.5° C. (270.5° F.), and when heated to 150–160° C. (302–320 F.) it evolves ammonia and decomposes with the formation of *biuret,* $C_2H_5N_3O_2$, and at higher temperatures with the formation of ammonium cyanate, melanuric acid, cyanuric acid, and cyanic acid. Urea dissolves in its own weight of water, more readily in hot water, and is soluble in 5 parts of cold 90 per cent. alcohol, in 1 part of boiling alcohol, but insoluble in chloroform or

ether. Heated with water under pressure urea is converted into ammonium carbonate. In contact with nitrogen trioxide, chlorine, bromine, hypochlorites, hypobromites, and acidulated solution of potassium permanganate, urea undergoes decomposition into carbon dioxide, water, and *nitrogen*. Dissolved in pure water urea keeps unchanged for a long time, but in the presence of putrifiable matter it is rapidly decomposed, yielding ammonia and carbon dioxide. Urea forms crystallizable compounds with acids, with metallic oxides, and with many neutral salts. *Urea hydrochloride* is very deliquescent. *Urea nitrate*, $CH_4N_2O.HNO_3$, is soluble in 8 parts of cold water and in 10 parts of cold alcohol, and nearly insoluble in nitric acid; it contains 48.78 per cent. of urea. *Urea oxalate* $(CH_4N_2O)_2.H_2C_2O_4$, crystallizes in scales which dissolve at 15° C. (59° F.) in 23 parts of water, but require a much larger quantity of solution of oxalic acid; it contains 57.14 per cent. of urea. The amount of urea in urine is frequently determined by forming the compound either with nitric or oxalic acid. Urea is identifiable by the biuret reaction, and the crystalline form of the nitrate and oxalate of urea. It is estimated by the volume of nitrogen evolved as per the reaction $3NaBrO + CH_4N_2O = 3NaBr + 2H_2O + CO_2 + N_2$. (See Allen's Hypobromite Process, Allen's Commercial Analysis, Vol. III., Part III., pp. 273–274.)

Action and Uses.—Urea injected into the veins of animals increases the secretion of urine and the output of urea. Because of this action it was proposed to be given by the mouth as a diuretic in man, and although its value is questionable it has been occasionally employed. Its dose is from 2 to 5 grains (0.12–0.30 Gm.) several times a day.

Allied Compound.—Formamide, $CH_3NO = CHO.NH_2$. It is produced on the dry distillation of ammonium formate, on heating a mixture of this salt and urea to about 140° C. (284° F.), on heating ethylformate and ammonia, and by various other processes. It is a colorless oily liquid, which in vacuo distils without decomposition below 150° C. (302° F.), and which is soluble in water and alcohol in all proportions, but is insoluble in ether. It is of interest as uniting with certain compounds and forming valuable remedial agents; see Chloralformamidum, p. 405, and Hydrargyrum Formamidatum, p. 785.

URTICACEÆ (The Nettle Family).

This is a peculiar family of some 41 genera and 500 species. They are mostly tropical or warm-temperate plants, of weedy character. The family is distinguished for the possession of many members having very tough bast-fibers, and others bearing stinging trichomes, like the nettles. In some tropical American Ureras, these trichomes become slender, piercing needles, several inches in length, very brittle, and producing a serious inflammation when piercing the skin in large numbers, frequently leaving fragments in the tissues. The irritating constituent is, at least in part, free formic acid. Medicinally, the family is noted for its general, powerful, and peculiar diuretic properties, the systematic study of which has been too long neglected.

Fig. 462.

Urtica dioica (½ Nat.).

Urtica or *Nettle* (*Brennessel*, G.; *Ortic brulante*, Fr.; *Ortigo*, Sp.) is the herbage of *Urtica dioica* L. and *U. urens* L., both common weeds of temperate Europe and Asia, and freely naturalized in the United States. The appearance of the first-named is here illustrated. *U. urens* has leaves about half as large, thinner, paler, 5-nerved and more deeply serrate, and the small and loose flower-clusters in axillary pairs. Notable quantities of ammonia have been distilled, and the distillate appears to possess the diuretic properties. The presence of a crystalline alkaloid has been reported. Several of the nettles are cooked as pot-herbs.

Parietaria officinalis L., and other species of *Parietaria* (*Wall pellitary*, E.; *Glaskraut*, G.; *Pariétaire, Perce-muraille*, Fr.; *Parietaria*, Sp.), is used similarly, but is not stinging.

UVA URSI, *U. S.*—Uva Ursi.

Uvæ ursi folia, Br.; *Folia uvæ ursi*, P. G.; *Folia arctostaphyli*, Ph. Nor.—*Bearberry, Barren myrtle, Rockberry, Mountain-box, Kinnikinnic*, E.; *Bärentraubenblätter*, G.; *Busserole, Feuille de raisin d'ours*, Fr.; *Uva ursina*, It.; *Gayuba*, Sp.; *Uva ursina, Buxubo*, Port.

The dried leaves of *Arctostaphylos Uva-ursi* (L.) Spreng. (*Arbutus U.*—L.; *A. officinale* Wim.—Fam. *Ericaceæ*).

Uva ursi is official in nearly all pharmacopœias, several of which use the name Arbutus. Most caution against mistaking the similar leaves of *Vaccinium Vitis-Idæa* L., *V. uliginosum* L., or *Arctostaphylos alpina* Spreng. Several require the red and violet reaction for gallic acid in the cold maceration treated with ferrous sulphate.

Origin.—The bearberry plant grows throughout most of the North Temperate Zone, in dry localities, either rocky or sandy, and especially in sandy pine woods. It is an evergreen shrub, the creeping stems often covering large patches to the exclusion of other plants. Its habit is shown in the accompanying illustration. The flowers are white or purplish white, the 5-seeded drupes bright red. The leaves are gathered in the autumn.

FIG. 463.

Arctostaphylos Uva-Ursi Sprengel.

Description.—Obovate or oblong-spatulate, 15 to 30 Mm. long, obtuse, slightly revolute on the margin, tapering into a very short and stout petiole, coriaceous; upper surface dark green, finely reticulate; lower surface slightly pubescent; odor slight; taste strongly astringent and somewhat bitter.

FIG. 464.

Uva ursi (Nat.).

The leaves of *Vaccinium Vitis-Idæa* L., the *Mountain cranberry* or *Cow-berry*, having much the same range as Uva ursi, can be distinguished by the presence of fine, blackish, bristly points on their lower surface. Those of *V. uliginosum*, the *Bog-bilberry*, are much thinner, and pubescent underneath.

Constituents.—The important constituents of bearberry are arbutin, ericolin, ericinol, ursone, 5 to 7 per cent. of tannin, giving a blue-black reaction with ferric salts, and a little gallic acid, all of which are common in related plants. A little resin and sugar are also present. *Arbutin*, $(C_{12}H_{16}O_7)_2 + H_2O$, is obtained from the decoction of the leaves by precipitating it with lead subacetate, treating the filtrate with hydrogen sulphide, and evaporating to crystallize. It forms neutral, colorless, silky needles, of a bitter taste, freely soluble in hot water and in alcohol, and sparingly soluble in ether. An aqueous solution of arbutin, rendered alkaline by ammonia or potassa, acquires a deep azure-blue color on the addition of phosphomolybdic acid. On being dissolved in strong nitric acid, arbutin yields, after the addition of alcohol, pale-yellow needles of *dinitro-arbutin*. By emulsin or by hot diluted sulphuric acid arbutin is decomposed into glucose and *hydroquinone* or *arctuvin*, $C_6H_6O_2$, and *methylhydroquinone*, $C_7H_8O_2$. Hydroquinone crystallizes in colorless, fusible, and sublimable prisms, is easily soluble in water, alcohol, and ether, and is also produced from kinic acid by destructive distillation. On oxidizing hydroquinone or arbutin with manganese dioxide and sulphuric acid, *quinone* is formed.

The mother liquor from the preparation of arbutin contains the yellow glucoside *ericolin*, $C_{34}H_{56}O_{21}$, which yields the volatile oil *ericinol*, $C_{10}H_{16}O$. Ericolin is brown yellow, odorless, bitter, hygroscopic, and soluble in water, alcohol, and alcoholic ether, nearly insoluble in ether, chloroform, and benzin, and is not precipitated by lead salts.

Ursone ($C_{20}H_{34}O_2$) is extracted by boiling alcohol from the residue left after washing the alcoholic extract with water and ether. It occurs in silky, tasteless, fusible, and sublimable needles, insoluble in water, dilute acids, and alkalies, sparingly soluble in ether and cold alcohol.

Pharmaceutical Preparations.—Fluidextract of Uva Ursi, U. S. P.; Infusion of Uva Ursi, Br.

Action and Uses.—Uva ursi combines diuretic, tonic and astringent properties. Its diuretic effect is thought to be due to the stimulating action of the arbutin upon the renal epithelium. A small portion of the arbutin is decomposed either in the intestines or in the tissues into glucose and hydroquinone, the latter acting as an antiseptic and preservative of the urine and imparting to it color varying from light green to dark brownish-green. This discoloration becomes more marked when the urine is exposed to the air and the hydroquinone undergoes oxidation. When decomposition of the urine occurs in the bladder, as in cystitis, the urine may be a very dark green color when voided.

Uva ursi is employed in subacute and chronic inflammations of the urinary organs. It is given with less benefit in disease of the secreting epithelium of the kidney than in inflammation of the mucous membrane of the pelvis of the kidney and of the urinary passages below. It is therefore less serviceable in nephritis than in pyelitis and cystitis. It relieves the incontinence, dysuria, and strangury of these affections, especially of the calculous varieties, by retarding decomposition of the urine and supposedly by obtunding the sensibility of the mucous membrane.

Uva ursi has also been used as a remedy in chronic bronchitis, diarrhœa, leucorrhœa, amenorrhœa, and uterine hemorrhage. In overdose it may cause nausea, vomiting, and diarrhœa. The dose of uva ursi is from 20 to 60 grains (1.30–4 Gm.), given preferably in fluidextract, although a decoction or infusion is sometimes used.

Arbutin may be substituted for uva ursi, though it was generally considered as efficacious as the crude drug. From 10 to 15 grains (0.60–1 Gm.) a day is the amount usually given.

Allied Drugs.—The genus *Arctostaphylos* contains about a score of species, a half dozen of which are similarly employed, especially *A. glauca* Lindl., the large-fruited *Manzanita* of western North America. These leaves are about 3.5 to 5 Cm. (1½–2 In.) long and two-thirds or more as broad, ovate-oval, acutish, entire, the base mostly rounded, pale green and glaucous. It contains more tannin than Uva ursi. It is said that the extract of the fruit of *A. arguta* Zucc., of Mexico, is given in doses of 1 to 1.5 grains as a hypnotic, and that it is recognized there as a narcotic poison. If this is true, it is perhaps due to the presence of andromedotoxin (see Ericaceæ).

Epigæa or *Trailing arbutus* (*Mayflower, Gravel-plant, Ground-laurel*) is the leaves of *Epigæa repens* L., a creeping, hairy, evergreen undershrub of eastern and northern North America, much beloved for the very early appearance of its pretty and fragrant flowers. The thin woody stem is covered with a brown bark. The evergreen leaves are alternate, about 5 Cm. (2 In.) long, petiolate, coriaceous, and reticulated ; their shape is ovate, the margin entire, the base heart-shaped, and the apex tipped with a short point. The flowers are in small axillary clusters, rose-colored or whitish, fragrant, have a deeply 5-parted bracted calyx, a salver-form corolla with the tube hairy inside, 10 stamens, and produce 5-lobed and 5-celled capsules containing numerous seeds. The leaves are inodorous, and have a bitterish and astringent taste. Its constituents, properties, and uses are nearly identical with those of Uva ursi and Chimaphila.

V.

VACCINE.

Vaccin, Fr.; *Impfstoff*, G.

Definition.—Cowpox vaccine, which is employed as a prophylactic against smallpox, consists of the material obtained from the vesicles appearing on animals of the bovine species which have been artificially infected with cowpox.

History.—During, and previous to, the eighteenth century the civilized countries of the world, particularly those of Europe, were overrun by numerous and devastating outbreaks of smallpox. Reports indicate that in some towns nearly one-tenth of the people died from this loathsome disease. It was observed by many that persons coming in contact with cattle, as dairymaids, etc., often contracted cowpox and were not susceptible to smallpox, but it remained for Jenner to recognize the importance of this fact, and to demonstrate the value of artificial inoculations with humanized cowpox virus as a means of protecting against the more dangerous disease, smallpox. After devoting more than twenty years to the study of the question, on the memorable day, May 14th, 1796, he vaccinated a boy, James Phipps by name, with material from the cowpox vesicles found on the hands of one of his father's milkmaids, Sarah Nelwes, who had become accidentally infected with cowpox from one of her master's cows. Some weeks later Jenner repeatedly inoculated the boy with smallpox virus, but was unable to produce the disease. Then he successfully vaccinated many other persons with the cowpox virus which he obtained from this boy, later testing them to see whether they could be inoculated with smallpox, but again he was unsuccessful in producing the disease, and soon the new method of protecting against smallpox was well established as a sanitary measure of the greatest importance.

Origin.—Since Jenner's time many attempts have been made to determine the original source of infection in cowpox. Two theories have been held, viz.: 1. That cowpox is a distinct disease that spontaneously attacks animals. 2. That cowpox is only modified smallpox.

Those believing the first theory have been able to show by directly inoculating many animals that it is very difficult to produce vesiculation by applying material from the vesicles of smallpox patients; and in those cases where a successful result follows the application of the smallpox material, typical smallpox or varioloid results when the material is transferred back from the animal to susceptible human beings.

Those holding the second view claim that the smallpox virus becomes modified by passage through a series of animals, and that typical vaccinia can be produced in bovine animals by vaccinating monkeys with smallpox virus, and then applying the material from the vesicles developing on the monkey to the heifers; and, as a further proof of the identity of the two diseases, they have found that children vaccinated with the material collected from the heifers develop typical vaccinia, and that they are protected from smallpox. We shall probably ultimately be able to trace the relation of the two diseases and show that they are but modifications of the same disease, or that they are very closely allied.

Many researches have been made to discover the vaccine organism; in fact, several experimenters have announced that they had actually found the bacterium or parasite producing the disease. So far none of the reports has been confirmed beyond controversy, but most authorities are inclined to believe that the disease is due to a parasite similar to that producing malaria.

Preparation.—Until recent years the arm-to-arm vaccination introduced by Jenner was performed—*i. e.*, the vaccine was taken from the vesicles forming on the arm of a child and employed for vaccinating other children. So many objections were raised against this method of vaccinating on account of the possibility of transmitting certain diseases, as syphilis, etc., that bovine lymph, obtained from artificially vaccinated heifers, came into use instead. In America the bovine vaccine was generally found on the market in the form of ivory points, the tips of which had been dipped into or moistened with the lymph as it exuded from the skin of the animal after the vaccine vesicles had been removed. Later it was found that the vaccinating principle contained in the cowpox vesicles was not harmed by glycerin, while bac-

teria accidentally gaining entrance to the material during the propagation and collection were destroyed. Still more recently it was found that the greater part of the vaccinating principle resided in the pulp of the vesicles instead of in the lymph which exuded from the skin after the vesicles had been removed. In fact, the lymph, which had been previously employed, simply washed off, and held in suspension the comparatively small amount of vaccinating material that remained after the pulp and crust covering had been removed and thrown away.

ANIMALS.—Nearly all ages and both sexes of bovine animals are employed, the choice mainly depending upon the ease with which propagators can obtain the different classes. Generally, however, in this country preference is given to those animals under three years of age. Some producers hold that young calves are particularly desirable. Judging from the results obtained by the use of vaccine in different countries, prepared from animals of different sexes and ages, it seems to make little difference which are employed.

LABORATORY.—A laboratory properly arranged for the propagation of vaccine should be divided into several sections:

1. A well-equipped, thoroughly aseptic bacteriological laboratory, divided into several rooms for grinding, testing, bottling, etc.

2. There should be an entrance ward into which the animals can be taken, subjected to careful veterinary examination, and tested with tuberculin before they are taken to the laboratory proper. This ward should be carefully isolated from other portions of the plant, in order that any diseased animals which may accidentally gain entrance to it may not contaminate the other sections.

3. A wash-room, where the animals may be properly prepared for vaccination.

4. Operating-room, fitted up with suitable tables, sterilized water, antiseptic solutions, and special appliances to be employed for the application of the vaccine to the animals and the collection of the ripe material.

5. Propagation ward, in which the animals are placed after vaccination. This should have stanchions, stalls, etc., of metal, stone, or other impervious material, in order that the animals may be kept in the cleanest possible condition.

6. An exit ward, into which the animals may be taken and kept for such time as is deemed advisable after the vaccine has been collected. There should be in connection with this room facilities for carrying on post-mortem examinations.

Vaccination of the Animal.—The animals which have been passed by the veterinarian are taken to the wash-room, thoroughly cleansed with soap and water, or in some cases also with antiseptics, and then taken to the operating-room, where the animal is placed upon a suitable table, the head and feet being fastened, so as not to injure the operator or contaminate the field of operation. The desired part of the body is then prepared for the reception of the seed vaccine. Usually in this country a large portion of the posterior part of the abdomen and inner surface of the thighs are shaved, scrubbed with soap, and disinfected with some antiseptic; finally the field of operation being rinsed thoroughly with sterilized water to remove all traces of antiseptic. Over the surface to be vaccinated linear incisions about half an inch apart are made with a sharp knife, just deep enough to wound the true skin, or a similar result is attained by cross-hatching small patches on the surface of the skin, or scraping off the cuticle in small spots. When the surface has been properly prepared for planting, as indicated, the seed vaccine is applied and rubbed in thoroughly, in order that the vaccinating organisms may come in direct contact with the living cells of the integument. After the vaccinated surface has dried for a short time, the animal is removed from the table, with or without the application of an aseptic dressing, and taken to the propagating-room, where it is kept for about five days, or until the vaccine is ripe, the strictest care being taken to keep everything pertaining to the animal scrupulously clean, it being necessary to keep an attendant constantly on duty day and night. Then the animal is taken to the operating-room again, placed upon the table, the vaccinated surface carefully cleansed with soap, water, and disinfectant, and dried spontaneously or with sterilized towels. The fully matured vaccine vesicles are carefully removed with a sterilized Volkmann spoon and placed in sterilized containers. After the entire crop has been removed, the wounded surface of the skin is treated with suitable antiseptics, and the animal is returned to the exit or detention ward, where it may be kept under observation; or in some laboratories the animal, as soon as it is removed from the table, is slaughtered and a post-mortem

examination made. The vaccine pulp taken from the animal is then sent to the laboratory proper, where every precaution is taken to conduct the subsequent operations as nearly aseptic as possible. This pulp is ground in a suitable machine with the requisite amount of glycerin, then emulsified by shaking. Sometimes it is necessary to pass the ground product through a fine sieve to remove large particles, etc. Before the vaccine is taken to the bottling-room it should be given a careful bacteriological examination and tested upon animals, in order to make certain by every possible means that no pathogenic contaminating bacteria are present; likewise it should be tested upon animals to determine whether it possesses the proper vaccinating properties. When these tests are completed the vaccine is stored in the refrigerator for a variable length of time, when it is taken to the bottling-room and put up in the aseptic tubes or placed upon the ivory points, which should be placed in a protecting glass envelope for the finished product as it appears upon the market.

Preservation of Vaccine.—Many different opinions have been expressed as to the keeping qualities of vaccine, but it is now well established that the product undergoes deterioration sooner or later, depending upon the conditions under which it is kept. Most propagators believe that the product should remain active for not less than three months from the time it has been marketed. In exceptional cases the vaccine may become inert shortly after it leaves the laboratory. High temperatures are particularly liable to destroy the preparation; consequently the custom has become recognized that vaccine, like similar biological products, should be kept in a refrigerator, or other very cool place, as much as possible until it is needed for use.

Physiological Action.—Little need be said under this heading, as it has already been indicated that the exact relation between smallpox and vaccine has not been clearly worked out. Certain it is that during the past hundred years or more it has been thoroughly proven that successful vaccination prevents in the vast majority of cases the development of smallpox. Many methods of applying vaccine are in use: however, in most cases it is applied by scarification, sometimes with the end of the ivory point, sometimes with the bistoury. Considerable difference in the results obtained are dependent upon the care with which the operation is carried out.

Blackleg Vaccine.—Blackleg vaccine consists essentially of the dried, powdered, and attenuated infected muscle of cattle dying from symptomatic anthrax.

Symptomatic Anthrax (*Charbon Symptomatique*, Fr.; *Rauschbrand*, G.) is known by the popular names of Blackleg, Black Quarter, Quarter Evil, Carbuncular Fever, etc., the point of attack being most often the muscles of the leg, which become dark and brawny, much swollen from the production of gas by the infecting bacteria, and give forth a crackling sound on pressure.

Bollinger and Fesor, 1878, discovered that this disease is caused by a bacillus which they called bacillus of symptomatic anthrax. Arloing, Cornevin, and Thomas a few years later determined its principal characteristics.

Symptomatic anthrax is a disease which attacks cattle and sheep, and should not be confounded with anthrax which attacks horses, mules, cattle, sheep, etc., and sometimes man. Arloing finally succeeded in the early eighties in preparing by drying, powdering, and attenuating the diseased muscles of animals dying from the disease a vaccine that proved extremely successful as a preventive of the disease. Arloing's original vaccine was a double-powdered vaccine, two strengths of virus being provided, of which the weaker was to be injected first, followed in about eight days by the stronger. This vaccine was soon supplanted by Kitt's single vaccine, which was of medium strength, requiring but one injection. Both of these products contained considerable inert material, as connective tissue, etc., which the stockman was obliged to filter out before using. These vaccines in turn were supplanted by an improved product, which could be employed by simply diluting the powder with sterile water just before using. Another attempt to simplify the product resulted in a small cotton cord saturated with the vaccinating material, a piece of the string being drawn through and a portion being left under the skin. Finally, the vaccine came to be put up in the very convenient form of blacklegoids (small pills), which can be injected with great rapidity with a special instrument designed for the purpose, which at one stroke of the needle deposits and leaves a blacklegoid underneath the skin, in the tissues of the animal.

The following is a brief description of the method of preparing the vaccine: The diseased muscles of animals dying from symptomatic anthrax are examined microscopi-

cally, ground, dried, connective tissue, etc., being removed so far as possible, attenuated, and powdered by heat, the degree of attenuation depending upon the virulency of the undried muscle. The double vaccines, as already intimated, consist of two injections of different degrees of virulency, while the single vaccine possesses a virulency of medium strength.

Blackleg vaccine is used only as a prophylactic against blackleg in cattle and sheep. It is never administered to horses, and must not be confounded with anthrax vaccine.

VALERIANA, *U. S.*—Valerian.

Valerianæ rhizoma, Br.; *Radix valerianæ*, P. G.; *Radix valerianæ minoris, R. v. sylvestris, R. v. montanæ.*—*Valerian-root, Common, Garden, Cat's, or Great Wild Valerian, Summer Heliotrope, All-heal, Herb Bennet, Vandal-root*, E.; *Baldrian*, G.; *Valériane officinale*, Fr.

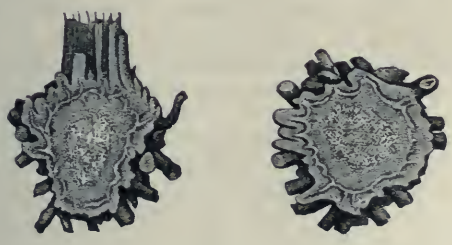
The dried rhizome and roots of *Valeriana officinalis* L. (*V. angustifolia* Tausch; *V. sambucifolia* Mikan.—Fam. *Valerianaceæ*).

Valerian is official in all pharmacopœias. The Portuguese gives it "*V. altissima* Mikan" (properly *V. exaltata* Mikan). Several specify that it be collected in dry places; the Portuguese, in moist places. The British and some others require autumn collection; several, spring collection. Several forbid the application of water in cleaning it after collection.

Origin.—Valerian is a native of Europe from the Mediterranean northward, and of Northern Asia, and is cultivated to some extent in Holland and England, and in this country in New England and New York. It is an herbaceous perennial, and grows in both wet and dry situations. It varies considerably in size and in foliage, and several of the varieties have been regarded by some botanists as distinct species. The plant is easily propagated from short horizontal runners. It is 0.6 to 1.2 M. (2–4 Ft.) high, branching at the top, has opposite, clasping, long-petiolate and oddly pinnate leaves, with from four to ten pairs of oval or lance-linear, entire or toothed, sessile, and smooth leaflets, and bears compound symes composed of numerous small, pinkish, fragrant, triandrous flowers. The fruit is an ovoid, compressed akene, crowned by a plumose pappus.

When collected, the drug is without the characteristic odor that it possesses when dried.

Fig. 465.



Longitudinal and transverse section of rhizome of valerian (Nat.).

Fig. 466.

Valerian (¾ Nat.).

Description.—Rhizome from 2 to 4 Cm. (about 1–1½ In.) long, and 1 to 2 Cm. (about ½ to nearly 1 In.) thick, upright, subglobular or obconical, truncate at both ends, often with a short horizontal branch attached, light brown or yellowish brown, internally whitish or pale brownish, with a narrow circle of white wood under the thin bark; roots numerous, rather coarse, brittle, brown, with a thick bark and slender, ligneous cord; odor peculiar, becoming stronger and unpleasant on keeping; taste camphoraceous and somewhat bitter.

When collected on dry soil, the drug is smaller, relatively shorter, lighter-colored, has more and smaller roots, and is less frequently cut to facilitate drying. A large amount of soil is likely to remain attached to the drug.

Admixtures.—Although valerian is readily distinguished from other medicinal roots, it has been sometimes observed sophisticated with poisonous drugs somewhat resembling valerian in appearance, and from contact with the latter having acquired to

some extent its peculiar odor. *Cynanchum Vincetoxicum* (p. 299) was noticed by Charbonnier (1877), *Veratrum album* (see below) by Holmes (1877), and *Sium latifolium* (p. 477) by Bernbeck (1880).

Constituents.—The most important constituent of valerian is its volatile oil (see below), which varies in proportion, variously stated as between about ½ and 3 per cent., the rhizome from dry soil, soon after drying, yielding the larger amount. Cultivated valerian seems to be less rich in volatile oil. Recent valerian on being distilled with water yields a distillate which, according to Schoonbroodt (1868), is neutral, or nearly so. Free isovalerianic acid does not exist in fresh valerian, but is generated from the volatile oil on exposure. The relative proportions of the volatile oil and isovalerianic acid must therefore vary with the age of the drug. Aschoff (1846) found in the root also malic, acetic, and formic acids. The constituents which are of less medicinal importance are tannin, extractive, sugar, starch, mucilage, resin, etc. It is believed that the large amount of manganese existing in the ash of valerian plays an important part in the conversion of the oil into the acid. A minute amount of the alkaloid *chatanine* has been reported, but little is known regarding it.

Oil of valerian, when freshly distilled, is a thin mobile liquid of yellowish-green or brownish-yellow color, a slight acid reaction, and a penetrating, characteristic, but not unpleasant odor. In the course of time the oil becomes more viscid and the color changes to dark brown; the acid reaction is intensified and the odor becomes decidedly unpleasant, owing to the increased formation of valerianic acid. The specific gravity of the oil ranges from 0.930 to 0.960, and its optical rotation varies from —8° to —12°. Its composition is rather complex; among the esters present are bornyl valerate (about 9.5 per cent. according to Gerock), and the formate, acetate, and butyrate of the same radical. Other constituents found are camphene, pinene, borneol, a sesquiterpene, and an alcohol, $C_{15}H_{26}O$, all of the lævorotatory variety. According to Flückiger, the highest boiling fraction of the oil contains an oil of blue color boiling at 300° C. (572° F.).

Pharmaceutical Preparations.—Ammoniated Tincture of Valerian, Fluidextract of Valerian, Tincture of Valerian, U. S. P.

Action and Uses.—The medicinal virtues of valerian reside in the volatile oil. While it is a feeble sedative to the nervous system, its quieting effect is considered to result largely from the psychic influence of its characteristic odor and taste. In large doses it causes a sense of warmth in the stomach, a slight quickening of the pulse, and sometimes nausea and vomiting. Still larger amounts produce purging and mental hebetude. Valerian is used as a quieting agent in hysteria and functional nervousness. It seems to be of particular service for the palliation of the nervous symptoms which occur at the menopause. It will sometimes benefit the delirium and ataxic symptoms which appear during exhausting fevers. The dose of valerian is from 10 to 60 grains (0.60–4 Gm.). The ammoniated tincture in the dose of 20 to 60 minims (1.30–4 Cc.) is most largely prescribed. The simple tincture and fluidextract are also efficient preparations. The dose of the volatile oil is from 3 to 5 minims (0.20–0.30 Cc.).

Allied Drugs.—The genus *Valeriana* L. contains probably not far from 200 species, and a large number of them possess apparently the composition and properties of the official.

V. Phu L. is a tall perennial of Western Asia and Southern Europe, and is occasionally cultivated. The root was known as *radix valerianæ majoris*, and consists of an oblique rhizome which is 10 to 15 Cm. (4–6 In.) long, about 12 Mm. (½ In.) thick, is distantly annulated, of a brown color, on the lower side furnished with numerous yellowish roots, and has a much weaker odor and taste than official valerian.

Indian Valerian (from *V. Wallichii* DC. ?) appears to be about equal in constituents and properties with the official, as is also true of *Mexican Valerian*, from *V. Mexicana* DC. and *V. Tolucana* DC.

Nardus Spica Celtica is the rhizome of *V. Celtica* L. of the Alps. It is thin, about 7.5 Cm. (3 In.) long, densely covered with brown scaly leaf-remnants, has long, simple roots on the lower side, and possesses a strong odor and taste of valerian.

Nardus Indica, Spica Nardi, or true *Spikenard*, formerly much employed, is obtained from *Nardostachys Jatamansi* DC. (*Valeriana* J.—Roxb.), of the same family, native of India. It is about 6 Mm. (¼ In.) thick, densely beset with numerous fibrous remnants of leaf-stalks, and has a bitter and aromatic taste and penetrating odor resembling that of serpentaria.

Japanese Valerian, credited to *Patrinia scabiosifolia* Link., is known in Japan as *Kesso*. It resembles Valerian in appearance, odor, and taste, but has a short rhizome, not more than 8 Mm. (⅓ In.) thick, and this is densely covered with dark-brown, scaly roots, which are 5 to 10 Cm. (2 to 4 In.) long.

VANILLA, *U. S.*—Vanilla.

Fructus (or *Siliqua*) *Vanillæ*, Ger. and Swed.; *Vanille*, Fr.; *Capsulæ Vanillæ*, Russ.; *Vaniglia*, It.; *Vainilla*, Sp.; *Baunilha*, Port.

The prepared nearly ripe fruit of *Vanilla planifolia* Andrews (*V. aromatica* Sw.; *Epidendrum Vanilla* L.; *Myrobroma fragrans* Salisb.; *V. sativa* Schiede.—Fam. *Orchidaceæ*).

Official in nearly all pharmacopœias.

Origin.—This species of vanilla is native of the tropical, forested valleys of the eastern Mexican Andes, where also it is cultivated upon a vast scale. The fruit was in use by the natives for flavoring their chocolate at the time of the discovery of America, but the time of the beginning of its cultivation is not known. Living plants were taken to Java in 1819, to Réunion in 1836, and thence to Mauritius, but culture was not successful until about 1850, when the process of artificially pollinating the flower was learned. Now it is cultivated in nearly all tropical countries where there is abundant moisture and a temperature which does not fall below 65° F. The commercial article is almost all, and the official wholly, the product of cultivated plants. The plant runs along the ground, but quickly climbs some neighboring tree by the aid of rhizoids or non-absorbing roots, which fasten into the bark. After a time the base usually rots. The stem is about as thick as the finger and very succulent, as are the oblong, thick leaves. In from 2 to 4 years, the leafy branches which have reached out into the light and air begin to flower and fruit, and the plant continues in bearing for 10 years, or even much longer. The growth of the season only is fruitful. The creamy-yellow flowers grow in racemes, and the pollination has to be effected by insects, or by hand, as usually practised. The fruit is fully grown in about 2½ months, but then takes twice as long to mature. There are from 3 to 10, or sometimes more in a cluster, and they resemble bananas in shape, but are several times more slender. Their weight averages about 40 to 45 pounds to the thousand. Their yellow color is a sign of approaching maturity, and they are at once gathered. If left upon the vine they would ultimately begin to turn brown at the tip and then to split into three valves, the dust-like seeds falling out. If not picked soon enough, this change will occur in curing them, and they must be sold at a lower price (though probably not inferior) as "splits." Those which are missed in picking are gathered, in poor condition, at a supplemental harvest, and are cut up into short lengths and sold as "cuts." More often the crop is gathered too soon, either by thieves or by the owner to prevent theft. While equally large, these immature fruits have not the quality, strength, or keeping properties of the others. The grower, or a middleman, sells the green fruits to the curer. They then have no aroma, the aromatic principle being developed by the curing process from the glucoside coniferin, secreted by internal hair-like fibrillæ which project into the central cavity. Lecomte has demonstrated that this coniferin is converted by a hydrolizing process into coniferic alcohol and glucose, and that the former is then converted by an oxydase into vanillin. Various methods for curing are employed in different countries, but the object of all is to drive the moisture out upon the surface and then to dry this portion, repeating the process as long as required. The first sweating is usually done in a sweating-box or by steaming, the following ones by heating them under woollen covers, and alternately exposing them to the sun or drying in ovens. They are sometimes dried over calcium chloride. They finally assume the appearance described below, and, if well-matured and carefully cured, are likely to form a superficial efflorescence of the crystals of vanillin. Such a coating is liable to be given them artificially, or such may be substituted for the natural one, which is first removed. The assorting of the cured fruits into classes depending upon imperfections of all kinds demands high skill. They are then bundled, all in a bundle being of uniform length and quality, from 50 to 75 in a bundle. In the anxiety not to overdry the fruits, resulting in loss of weight, there is danger of underdrying them, with the result of having them mould inside of the bundle or under the string.

Description.—From 15 to 25 Cm. (6–10 In.) long, and about 8 Mm. (⅓ In.) thick, linear, narrowed and bent or hooked at the base, rather oblique at the apex, wrinkled, very dark brown, glossy-leathery, the integument very thin, frequently coated with crystals, 1-celled, and containing a blackish-brown pulp, with numerous minute seeds, and more or less acicular crystals; odor and taste peculiar, very agreeable.

FIG. 467.

Vanilla (reduced ⅓): *a*, fresh fruit, Mex.; *b*, Mexican; *c*, Bourbon; *d*, Mauritius; *e*, Tahiti; *f*, Vanillons; *g*, Vanillons braided.

Varieties.—Of the official vanilla, aside from its commercial grades, we have a number of distinct varieties, named according to the producing countries. Mexican vanilla has been greatly preferred by the American consumer until recently, when the Bourbon variety has come to enjoy almost as good a repute. The former only occasionally reaches or exceeds 9 inches in length, and when of first quality is of a dark-chocolate color, otherwise of a very dark brown. It is thin-skinned, glossy and pliable, and usually bears no crystals, though it formerly did so. It has a prominent hook at the upper end. The Bourbon or Réunion fruit is very similar, but usually crystal-covered. The crystals are sometimes, as in Fig. 467, *c*, fine and downy, at others laminar, as in Fig. 467, *d*. The Mauritius is very similar. Seychelles vanilla looks similar, but the odor is usually distinctly less fine. Guadeloupe looks like Mexican, but has a harder or dryer skin and coarser furrows, and a much inferior odor. Java vanilla is short and small, but of excellent quality. It is seldom imported to the United States. The prices of the different sorts in the New York market, January 1, 1901, ranged about as follows: Mexican, $8.50–$13; Guadeloupe, $6.50–$7.50; Java, $4–$4.75; Seychelles, $4–$8; Bourbon, $4.50–$8.50; Comores, $4–$4.50; Mauritius, $4–$7; Tahiti, $1.50–$2; Vanillons, $1.25–$1.75.

There are few cases in which the highest economy is so well subserved by the pharmacist who has a discriminating patronage as in purchasing one of the better

vanillas, even at the higher price. Inferior fruits or even fictitious substitutes may yield a stronger odor, but never so fine nor permanent, nor so agreeable to the cultivated taste as an amount of the better sorts representing the same value.

Constituents.—The important odorous and flavoring constituent of vanilla is *vanillin*, which exists in official vanilla to an extent varying from 1.5 to 3 per cent. That this is not the only essential is clear, however, from the fact that no pure artificial vanillin has been found to yield so agreeable or permanent a product as a preparation of the fruit itself. This odor is attributed partly to a small amount of a peculiar balsam, and also to a resin, though the latter by most is considered as detrimental to the finest flavor. Leutner's analysis also showed the presence of about 10 per cent. of sugar, 6.6 per cent. of gum, 4 per cent. of resin, 4.7 per cent. of ash, and a little wax, tannin, oxalic, and other acids.

The constituent which causes the inflammation upon the hands of workers in vanilla is yet unknown. It has been attributed to a parasitic insect, and also to the use of cardol for coloring inferior vanillas, though the symptoms are not satisfactorily accounted for by either.

The quantitative determination of vanillin may be effected by the following method proposed by E. Schmidt: 3 to 5 Gm. of vanilla are triturated with well-washed and dried sand (preferably sea-sand) until a light pulverulent mass is produced. This mixture is exhausted with ether in a Soxhlet apparatus, and the ethereal extracts are united and shaken out with successive portions of 5 Cc. of a saturated solution of sodium acid sulphite diluted with an equal volume of water. The united aqueous liquids are treated with diluted sulphuric acid until the acid is in excess, the resulting sulphur dioxide being removed by a current of carbon dioxide. Finally the liberated vanillin is shaken out with ether, the latter evaporated at a low temperature, 35° to 45° C. (95° to 113° F.), and the residue dried over sulphuric acid to constant weight.

Pharmaceutical Preparation.—Tincture of Vanilla, U. S. P.

Action and Uses.—Vanilla possesses no active medicinal properties. It is employed as a flavoring agent for confections, pastry, etc.

Unofficial Vanillas.—Unofficial vanillas are those which, coming from the official plant, do not yet correspond with the official description, and also some derived from other species. To the former class belong the *splits* and *cuts* referred to under *Origin*, as well as several thick-skinned varieties, apparently from wild plants, called in the native *cimarrona*, *mestiza*, *puerca*, etc. To the latter class belong the *pompona*, derived from *V. pompona* Scheide, wild and cultivated in the same region as the other, and believed by the natives to be the ancestor of *V. planifolia*, they regarding the latter as a cultivation derivative of it; also the vanillas (see Fig. 467, *f* and *g*) derived from one or more uncultivated species. The pods of both are short, thick, rough, and tough, and the odor rankly fruity, or pruney, in the latter respect quite resembling the Tahiti variety.

Vanillin has been reported in the flowers of several *Orchidaceæ*, especially in *Habenaria nigra* R. Br. (*Nigritella suaveolens* Koch). It has also been reported in the fruits of one or more plants of the same family.

VANILLINUM, *U. S.*—Vanillin.

Vanilline, Fr. Cod.; *Vanillin, Vanillekampher, Protocatechualdehydmethylæther*, G.

Methylprotocatechuic aldehyde, occurring naturally in vanilla, or made artificially from several orthodihydroxybenzene derivatives.

Formula, $C_8H_8O_3$ or $C_6H_3.OH.OCH_3.COH$. Molecular weight, 150.92.

Preparation.—For commercial purposes vanillin is manufactured on a large scale, both in this country and abroad, synthetically by one of the following processes; preferably perhaps from the first-named:

From Eugenol: This, the chief constituent of oil of cloves, having been separated from the latter, is boiled with acetic anhydride, whereby it is converted into acetyl-eugenol, $C_{10}H_{11}(C_2H_3O)O_2$. A dilute solution of acetyl-eugenol is next oxidized by means of a slightly warmed weak solution of potassium permanganate, whereby acetyl-vanillin is formed, the mixture is filtered, and the filtrate made alkaline with potassium hydroxide, after which it is evaporated to a small volume, by which treatment the newly-formed acetyl-vanillin is converted into vanillin. After acidulation with sulphuric acid, the liquid is shaken out with ether, which takes up the vanillin and yields the same upon

subsequent evaporation at a low temperature. By this method vanillic acid and vanilloylcarbonic acid are also formed, which are removed by appropriate methods of purification.

From Coniferin: This glucoside, $C_{16}H_{22}O_8 + 2H_2O$, obtained from the cambium sap of pines and similar trees, is dissolved in warm water, and then added in the form of a concentrated solution slowly to a moderately warm mixture of potassium dichromate, sulphuric acid and water, the mixture being finally heated to boiling for 3 hours with the aid of a reflux condenser. The reactions resulting in the formation of vanillin by this method include the hydrolysis of the coniferin, through the agency of the acid, into dextrose and coniferyl alcohol, and the oxidation of the latter into vanillin with elimination of aldehyde, thus: $C_{16}H_{22}O_8 + H_2O = C_6H_{12}O_6 + C_{10}H_{12}O_3$; $C_{10}H_{12}O_3 + O = C_8H_8O_3 + C_2H_4O$. The vanillin may be recovered direct by passing steam through the mixture or it may be extracted with successive portions of ether, after filtration of the liquid, and the ether recovered, leaving the vanillin in the form of a yellowish oily liquid, which congeals to a crystalline mass after a few days and may be purified by solution in warm water and treatment with animal charcoal, and final recrystallization.

Properties and Tests.—Vanillin occurs in fine white, crystalline needles, having the odor and taste of vanilla, and having an acid reaction. Soluble in about 100 parts of water at 25° C. (77° F.), and in 15 parts at 80° C. (176° F.). It is easily soluble in alcohol, ether, glycerin, or chloroform. When heated to between 80° and 81° C. (176° and 177.8° F.), it melts, and at 285° C. (545° F.) it can be distilled without decomposition in a current of carbon dioxide, leaving no residue. It is easily soluble in aqueous solutions of alkali hydryoxides, and from the combinations thus formed it is precipitated at once by the addition of acids. An aqueous solution of vanillin gives, with ferric chloride test solution, a blue color; if the mixture be boiled, the blue color changes to brown, and on cooling a white precipitate of dehydro-divanillin separates. Vanillin is extracted completely from its solution in ether by shaking with a saturated aqueous solution of sodium bisulphite, from which solution it is precipitated by the addition of sulphuric acid. An aqueous solution of vanillin will give, on the addition of lead acetate test-solution, a white precipitate of a lead compound of vanillin soluble in hot water, and crystallizing, on cooling, in scales. On warming 0.1 Gm. of vanillin with concentrated alcoholic solution of sodium hydroxide, adding chloroform and again warming, it should not give an odor of phenyl-isocyanide (absence of acetanilide).—U. S.

Vanillin partakes both of phenolic and aldehydic characters and unites with bases to form saline compounds. By action of nascent hydrogen it is converted into vanillin-alcohol, $C_8H_{10}O_3$, and by oxidizing agents into vanillic acid, $C_8H_8O_4$, both of which crystallize in the form of colorless needles, and melt at 115° C. (239° F.) and 207° C. (404.6° F.) respectively. If fused together with potassium hydroxide, vanillin is converted into protocatechuic acid, $C_6H_3(OH)_2COOH$.

Vanillin has at times been extensively adulterated, and even recently accounts have been published of gross sophistication. Benzoic acid, especially prepared for that purpose, acetanilide, boric acid, terpin hydrate, and coumarin have been employed, and adulteration to the extent of 50 per cent. has been frequent, and at times even as high as 90 per cent. Acetyl-isoeugenol has also been met with in commercial vanillin. The latter may be detected by the abnormal crystals revealed under the microscope and the beautiful red color developed with sulphuric acid instead of the characteristic lemon-yellow color found in the case of pure vanillin.

Since vanillin is largely used for the manufacture of vanilla extracts, the addition of coumarin has often been made for the purpose of cheapening the product, and may be detected by the method suggested by Prescott and Hess (*Jour. Am. Chem. Soc.*, 1899), as follows: 25 to 100 Gm. of the suspected extract are evaporated at about 80° C. (176° F.) in an evaporating dish, adding water from time to time to keep the volume constant. After removal of the alcohol add normal lead acetate solution drop by drop until no further precipitation occurs, filter through asbestos, and wash the precipitate with a few Cc. of hot water. The cooled filtrate is then extracted with repeated portions of ether or chloroform and the combined ether-extracts shaken out with successive portions of dilute ammonia (strong ammonia 1 part and water 2 parts) until the last portion used is not colored yellow. The ammoniacal solution extracts the vanillin, the latter as an aldehyde entering into combination with the ammonia, forming aldehyde-

ammonia, which is very soluble in water. The ether solution is then washed with 2 Cc. of water and evaporated spontaneously or in a desiccator. The residue is exhausted with ligroin (fraction of petroleum boiling between 30° and 40° C. (86° and 104° F.), and the residue obtained on evaporation of the same, dried at a temperature not exceeding 45° C. (113° F.) and weighed as coumarin. Coumarin may by this method also be detected in commercial vanillin, as it will not be extracted from an ether solution of the suspected article by ammonia-water.

Vanillin has been used in connection with phloroglucin as a test for free hydrochloric acid in gastric juice. The reaction, better known as *Günzburg's reaction*, is very sensitive and capable of detecting as little as $\frac{1}{20}$ per cent. of the acid. Two solutions are used, the one consisting of phloroglucin (2 Gm.) and alcohol (15 Gm.), and the other of vanillin (1 Gm.) and alcohol (15 Gm.). The test is made by mixing 3 drops of each of the solutions with 5 drops of gastric juice in a porcelain dish and warming while rotating the dish gently. In the presence of free hydrochloric acid an intensely red mirror is produced.

Action and Uses.—Vanillin is largely employed in the manufacture of vanilla extracts and perfumes. It was proposed as a remedy in atonic dyspepsia, but is rarely used. The dose is from $\frac{1}{4}$ to 1 grain (0.015–0.06 Gm.).

VERATRINA, *U. S., Br.*—Veratrine.

Veratrinum, P. G.; *Vératrine*, Fr. Cod.; *Veratrin*, G.

A mixture of alkaloids obtained from the seed of *Asagræa officinalis* (Chamisso and Schlechtendal) Lindley (Fam.—*Liliaceæ*).—U. S.

An alkaloid or mixture of alkaloids prepared from cevadilla, the dried ripe seeds of *Schœnocaulon officinale*.—Br.

Preparation.—The British Pharmacopœia directs that cevadilla seed, having been freed from the capsules and powdered, be moistened with 90 per cent. alcohol and percolated with that menstruum until exhausted. The resulting tincture is concentrated until precipitation just begins, and poured, while hot, into 12 times its volume of cold distilled water, whereby resin, fat, and some coloring-matter are precipitated. After filtration through calico the residue on the strainer is washed with water until ammonia-water ceases to cause precipitation in the filtrate. Upon addition of ammonia-water to the filtrate the alkaloids are precipitated and then washed with water to remove impurities. The moist alkaloidal precipitate is suspended in water and dissolved by adding sufficient hydrochloric acid, the solution decolorized with animal charcoal and again precipitated with ammonia. Finally, the precipitate is collected on a filter, washed with cold water to remove ammonium chloride, and dried, first on bibulous paper and then by warming.

The directions of the French Codex are similar. The powdered seed are to be exhausted with 80 per cent. alcohol containing a little sulphuric acid, and the alkaloids liberated with slaked lime. The alkaloids are then dissolved in very dilute sulphuric acid, treated with animal charcoal, precipitated with ammonia-water, and finally dried.

Properties and Tests.—The commercial article, officially recognized as veratrine, occurs as a white, or grayish-white, amorphous powder, odorless, but causing intense irritation and sneezing when even a minute quantity reaches the nasal mucous membrane; having an acrid taste, and leaving a sensation of tingling and numbness on the tongue. It should be tested with great caution. Slightly hygroscopic in moist air. Soluble in 1750 parts of water, 2.2 parts of alcohol, 3 parts of ether, and in 1 part of chloroform at 25° C. (77° F.); soluble in 1300 parts of water at 80 C. (176° F.); very soluble in benzene and amyl alcohol; insoluble in petroleum benzin. When heated to 145° C. (293° F.) it softens, and melts at 152° C. (305.6° F.). Upon ignition it is consumed, leaving no residue. Its alcoholic solutions are alkaline to red litmus-paper. On triturating veratrine with sulphuric acid, in a glass mortar, the yellow or orange-red solution exhibits, by reflected light, a greenish fluorescence, which becomes more intense upon the addition of an equal volume of acid. Upon standing, the solution gradually assumes a deep-red color. Sulphuric acid, when heated with veratrine, gives a cherry-red color. Sulphuric acid containing a trace of selenous acid produces a brownish-green color. Sulphuric acid added to a mixture of 1 part of veratrine and 6 parts of sugar produces a green color, changing to blue, and the mixture then becomes colorless.—U. S. Soluble in 3 parts of 90 per cent. alcohol (4 parts.—P. G.) or chloroform

(2 parts.—P. G.), in 6 parts of ether at 15.6° C. (60° F.), and in dilute acids, leaving slight traces of an insoluble brown resinous matter. It forms a yellow solution with nitric acid. Warmed with hydrochloric acid it dissolves with production of a blood-red color lasting several days. Heated with access of air, veratrine melts to a yellow liquid and finally burns away leaving no appreciable residue.—Br. An alcoholic solution of veratrine must not be precipitated by platinic chloride solution.—P. G.

Composition.—As the term "veratrine" has been applied to several distinct substances, that of Couerbe and Wright and Luff is now called *veratridine*, and that of Merck, Bosetti, Ahrens and others is called *cevadine*. The veratrine of the pharmacopœias is a mixture consisting chiefly of cevadine and veratridine. Many investigators have studied the alkaloids, but with little uniformity in their findings. Allen (1895–96), however, has confirmed Wright and Luff's (1878) widely accepted three alkaloids, *cevadine*, *cevadilline*, and *veratridine*, and the two new alkaloids of Merck (1891), *sabadine* and *sabadinine*. Keller's *sabatrine* is thought to have been a mixture, and his *sabadilline* is probably identical with cevadilline.

Cevadine, $C_{32}H_{49}NO_9$, separates from alcohol in anhydrous needles, which melt at 205° C. (401° F.), become opaque and white on exposure to air, and dissolve in chloroform, acetone, carbon disulphide, acetic ether, and amylic alcohol, but with difficulty in petroleum spirit. Its solutions are optically inactive. By saponification with alcoholic solution of sodium hydroxide it yields methylcrotonic acid and *cevine*, $C_{27}H_{43}NO_8$, with nitric acid it is wholly oxidized, and with alkaline potassium permanganate yields acetic and oxalic acids. It is exceedingly toxic and very irritating to the nasal mucous membrane. A solution of cevadine in nitric acid upon being warmed assumes a violet color, which changes to scarlet red on boiling. It yields a yellow solution with cold sulphuric acid, the color changing to blood red upon warming. "The facility with which cevadine undergoes hydrolysis is the cause of the formation of much amorphous alkaloid and other products in the extraction of the sabadilla alkaloids."—(Allen). It is the most abundant alkaloid in sabadilla seeds, and is said to occur also to a slight extent in the rhizome of veratrum viride.

Veratridine, also known as veratrine, and so called by its discoverers, Wright and Luff, $C_{37}H_{53}NO_{11}$, occurs as an amorphous resinous mass, melting at 180° C. (356° F.), which dissolves in concentrated sulphuric acid, with a yellow color, soon changing to deep red. The solution does not, like that of cevadine, show a dark-green fluorescence. It is rendered horny and insoluble by dilute nitric acid. In sulphuric acid it dissolves readily, forming salts which crystallize in fine needles, and, on drying, unite to form a horny, translucent mass. By saponification it yields veratric acid and *verine* or *veratroïne* $C_{23}H_{45}NO_8$, a substance closely allied to cevine.

Cevadilline, $C_{34}H_{53}NO_8$, is an amorphous alkaloid insoluble in water and ether, and yielding on saponification cevadic acid and *cevilline*. It is not sternutatory. *Sabadine*, $C_{29}H_{51}NO_8$, occurs in crystals which melt at 238° to 240° C. (360.4–464 F.), and are soluble with difficulty in water and ether, and insoluble in petroleum spirit. In warm, but not in cold, solution it is precipitated by alkalies, alkaline carbonates, or ammonia. It is "not sternutatory" (Merck), "moderately sternutatory" (Allen). *Sabadinine*, $C_{27}H_{48}NO_8$, crystallizes in hair-like needles, which melt at 160° C. (320 F.), and decompose if heated above this temperature. It is moderately soluble in water, very slightly in ether, and readily in alcohol and chloroform. It is not sternutatory. The hydrochloride is crystallizable and soluble in water.

Pharmaceutical Preparations.—Oleate of Veratrine, Veratrine Ointment, U. S. P.

Action and Uses.—Veratrine has a bitter and acrid taste, and a minute portion of it placed upon the tongue produces a peculiar and persistent numbness and tingling with irritation of the throat and salivation. Introduced into the nostrils it causes intense irritation in the nasal mucous membrane, and when applied to the skin in alcoholic solution it causes tingling and irritation followed by a sense of numbness. If in concentrated solution, it causes vesication and may be absorbed in sufficient quantities by the skin to produce poisoning. The drug has been used internally as a remedy for neuralgic pains of all kinds, but owing to its very poisonous properties and the feeble curative effects which follow its use, it is now rarely employed. It has also been given internally in acute articular rheumatism and in palpitation of the heart. Externally it

has been used as a counterirritant, in the form of the ointment (Unguentum Veratrina), over neuralgic nerves and swollen joints. Such an ointment must be applied with caution, lest the drug be absorbed by the skin and produce systemic effects. In cases of poisoning by the drug the stomach should be emptied by an emetic or the stomach pump. Tannic acid should be given as a chemical antidote, and the heart and respiration should be supported by ammonia, ether, strychnine, digitalis, and the use of artificial respiration.

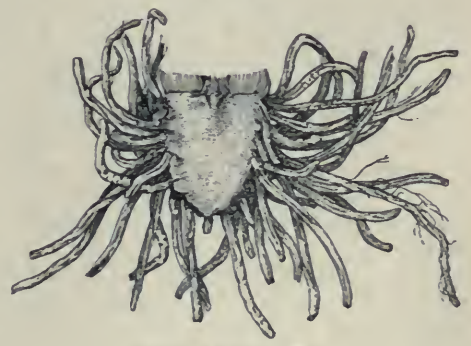
VERATRUM, *U. S.*—Veratrum.

Veratri rhizoma (*radix*).—*Hellebore.*

The dried rhizome and roots of *Veratrum viride* Aiton (*V. album viride* Baker; *Helonias v.*—Ker.; *Melanthium virens*—Thunb.), American or Green ("Am. White") Hellebore, or of *V. album* L., the European or White Hellebore (Fam. *Liliaceæ*).

Origin.—*V. viride* (*Swamp, Big* or *False veratrum* or *hellebore, Indian poke, Crow poison, Itch-weed, Tickle-weed,* E.; *Vératre vert,* Fr.; *Grüner Germer,* G.; *Vedegambre Elebero verdo,* Sp.; *Veratro* or *Hellebero verde* or *Americano,* Port.) should not be confused with the *European Green Hellebore* (*Helleborus viridis* L.—Fam. *Ranunculaceæ*), and it is always well to specify it as *American Green Hellebore.* It is a stout, luxuriant, perennial herb of rich swamp lands throughout eastern North America. It grows to a height of 2 to 4 feet, and is densely leafy, the lower leaves often more than a foot in length, broadly oval, acute, stiff, and strongly ribbed and plaited, by which it is well distinguished from the less tall skunk's-cabbage which usually grows with it. The upper leaves become successively smaller and narrower, and the stem terminates in a long, narrow panicle of small, yellowish-green, rigid, persistent 3-merous flowers. The herbage withers rather early, after which the rhizome is gathered. Through gross ignorance or carelessness the herbage has occasionally been collected, cooked, and eaten for American cowslip (*Caltha*), with poisonous results. Bare-legged boys often suffer from a mild itching by coming into contact with the plant, whence two of its common names. It is said to have been used both as an ordeal poison and as a medicine by the Indians, whence the name "Indian Poke." *V. album* grows in similar locations, almost throughout Europe and Asia, to Japan, and is of closely similar appearance, its flowers yellowish white.

FIG. 468.



Veratrum viride (½ Nat.).

Description.—*V. viride.*—Rhizome upright, ovoid, or obconical, 2.5 to 7 Cm. (1–3 In.) long and ⅔ as broad, externally light, to dark, brown or blackish, frequently bearing at the summit some coarsely fibrous remains of leaf-bases, densely clothed at the sides with coarse roots; internally grayish, or yellowish, white, exhibiting numerous short, irregular wood-bundles; roots about 10 to 20 Cm. (4–8 In.) long and about 1 or 2 Mm. ($\frac{1}{25}$—$\frac{1}{12}$ In.) thick, light yellowish brown, much shrivelled, the surface somewhat reticulate-wrinkled; inodorous, but the powder highly sternutatory; taste bitterish and very acrid.

V. album is of very similar appearance, and is frequently indistinguishable, though if carefully and recently dried its roots are paler, or nearly white.

The powders cannot be distinguished by structure, and the cheaper V. album has been largely employed to adulterate V. viride. Denniston reports that concentrated sulphuric acid turns the *viride* powder orange red, the *album* bright brick red, but it may be doubted whether this distinction would hold good for all lots, differently collected and preserved for different periods. The question is of little interest, except technically, since what evidence we have indicates the practical identity of the two as medicinal agents, which consideration has induced their union in one definition, instead of restricting the latter to V. viride, as was done in the preceding edition of the Pharmacopœia. V. album has been adulterated with asphodel, but the latter is distinguished by the greater length and slenderness of its rhizome, and the clubbed or fusiform appearance of its roots.

Constituents.—While at one time much confusion existed regarding the constituents of the two varieties (green and white) of veratrum, careful investigation by Wright and Luff (1879) and Salzberger (1885–1890) has shown that they are practically identical, although Wright and Luff claim that cevadine (see VERATRINA) is present in *veratrum viride* but not in *veratrum album.* Besides fat, resin, gum, and starch, several alkaloids are known to be present, of which the most important, from a physiological point of view, is undoubtedly protoveratrine (about 0.03 per cent.); then follow jervine (about 0.10–0.13 per cent.), rubijervine (about 0.005 per cent.), and pseudojervine; a bitter glucoside, veratramarin, and jervic acid, $C_7H_4O_6 + H_2O$, identical with chelidonic acid, are also present. Protoveratridine, likewise reported, has been shown to be a decomposition-product. Veratralbine and veratroidine, which were formerly looked upon as distinct alkaloids, are not now so considered. Their true character has not yet been established, and they are probably mixtures of amorphous bases.

According to Salzberger, two methods, designated respectively as the baryta method and the phosphoric acid method, may be employed for isolation of the alkaloids. The baryta method: The rhizome, in moderately fine powder, is intimately mixed with $\frac{1}{8}$ of its weight of powdered barium hydroxide and $\frac{1}{2}$ its weight of water then added. The mixture is then treated with 3 successive portions of ether, the ethereal liquids being subsequently mixed and distilled in a current of hydrogen at low temperature. The resulting dark-green syrupy residue gradually deposits wedge-shaped crystals of jervine, which are filtered and washed with ether until the latter runs off colorless. By treating the crude jervine with absolute alcohol, insoluble protoveratridine is removed, and the clear solution containing jervine and rubijervine may then be crystallized. The crystalline mass is digested on a water-bath with diluted sulphuric acid, whereby the sparingly soluble jervine sulphate is easily separated from the readily soluble rubijervine sulphate. By decomposing jervine sulphate with sodium carbonate, the alkaloid jervine is liberated and may be recrystallized from alcohol. The solution of rubijervine sulphate upon addition of ammonia-water yields rubijervine in the form of a gelatinous precipitate.

The phosphoric acid method: After treatment of the powdered rhizome with ether or petroleum benzin, for the removal of fat and resin, it is exhausted with 80 per cent. alcohol, and the resulting tincture is distilled in vacuo. The residue left after recovery of the alcohol is then treated with water acidulated with acetic acid, insoluble matter being removed by filtration, and the filtrate treated with metaphosphoric acid as long as precipitation occurs. Jervine and rubijervine are thus removed as insoluble compounds. After filtration the clear solution is rendered alkaline by addition of ammonia-water and then shaken out with ether. Upon evaporation of the ethereal solution protoveratrine crystallizes out, and may be further purified by recrystallization from 90 per cent. alcohol. By shaking the alkaline liquid, already treated with ether, out with chloroform, pseudojervine may be isolated and recovered upon evaporation of the chloroformic solution.

PROTOVERATRINE, $C_{32}H_{51}NO_{11}$.—This, the most important of the veratrum alkaloids, occurs in colorless shining crystals belonging to the monoclinic system, which are permanent in the air, and melt at 245° to 250° C. (473°–477° F.). It is insoluble in water, benzene, and petroleum benzin, and dissolves with difficulty in most other solvents. Chloroform and boiling 96 per cent. alcohol are the best solvents. Its alcoholic solution rapidly changes red litmus-paper to blue. It forms a greenish-colored solution with concentrated sulphuric acid, which gradually changes to blue and finally to violet. If dissolved in diluted alcohol, it will usually be obtained in the form of a colored syrupy residue upon evaporation of the solvent, only a small portion crystallizing.

JERVINE, $C_{26}H_{37}NO_3$.—This alkaloid constitutes somewhat more than $\frac{1}{2}$ of the total alkaloidal content of the drug. When repeatedly crystallized from alcohol, it occurs in shining satiny, prismatic crystals, which melt at 238° to 240° C. (460.4°–464° F.). Jervine frequently separates from concentrated solutions in wedge-shaped crystals. It is readily soluble in ethyl, methyl, and amyl alcohol, chloroform and acetone, but difficultly in ether, and is insoluble in benzene and petroleum benzin. It is apparently not affected by boiling hydrochloric acid or alcoholic solution of potassium hydroxide. Jervine dissolves in concentrated hydrochloric acid, producing a yellowish color which soon changes to green. Its sulphate, nitrate, and hydrochloride are difficultly soluble, but the acetate and phosphate are readily soluble. The addition of ammonia-water to solu-

tions of the salts precipitates the alkaloid in the form of delicate needles. Jervine is only feebly toxic.

RUBIJERVINE, $C_{26}H_{43}NO_2 + H_2O$.—When recrystallized from hot alcohol this base is obtained in well-formed long prisms, which melt at 240° to 246° C. (464°–468.8° F.). It is easily distinguished from jervine by the ready solubility of its sulphate and nitrate. It yields a yellow solution with concentrated sulphuric acid, gradually changing to orange and finally to dark red. If warmed with hydrochloric acid, a reddish-violet color is produced. Rubijervine is physiologically inert.

PSEUDOJERVINE, $C_{29}H_{43}NO_7$.—Discovered by Wright and Luff in 1879 and its existence subsequently confirmed by Salzberger. It crystallizes from alcohol in thin, broad, hexagonal plates, which melt at 300° to 305° C. (572°–578.6° F.). It is difficultly soluble in alcohol and benzene, and almost insoluble in petroleum benzin, ether, and toluene. Its alcoholic solution changes the color of red litmus-paper to blue. Concentrated sulphuric acid forms a green-colored solution with pseudojervine. It is precipitated from solutions of its salts in the form of curdy flocculi. Like the preceding base, it is physiologically inert.

PROTOVERATRIDINE, $C_{26}H_{45}NO_8$.—According to Salzberger, who first isolated this base, it does not preëxist in the drug, but is the result of decomposition of protoveratrine by action of barium hydroxide, in proof of which he states that it is not met with when the phosphoric acid method for isolating the alkaloids is employed. Being almost insoluble in alcohol, it is left behind when crude jervine is treated with that solvent, as stated above. It may be obtained in the form of colorless square plates, which melt at 265° C. (509° F.). The solutions of its salts have an intensely bitter taste. In contact with concentrated sulphuric acid the base produces a violet color, changing to cherry-red. Protoveratridine is non-toxic and possesses no sternutatory properties.

Pharmaceutical Preparations.—FLUIDEXTRACT OF VERATRUM, TINCTURE OF VERATRUM.—U. S. P.

Action and Uses.—Veratrum is a powerful sedative to the nervous, respiratory, and circulatory systems. Because it is prone to produce vomiting when taken in poisonous dose it frequently fails to destroy life, since emesis takes place so early that the greater part of the ingested drug is expelled before it is absorbed. Because of its powerful sedative influence upon the heart, medicinal doses slow the pulse and diminish arterial tension. The action on the heart is chiefly exercised by the alkaloid, jervine, but the slowing of the pulse is due to a powerful stimulant influence exercised by the alkaloid, protoveratrine, upon the pneumogastric nerves. Not only does the jervine in veratrum lower arterial tension by depressing the heart, but it also powerfully depresses the vasomotor centre. Indeed, aside from the nitrites, such as nitroglycerin, it is the most powerful drug for reducing arterial tension that we have. Much difference of opinion exists as to the real value of veratrum as a medicinal agent. Certain practitioners of large experience use it for many conditions, and claim excellent results in the early stages of acute inflammation, while others rarely if ever employ it. There seems to be, however, a general consensus of opinion that the drug exercises its best effects in the treatment of puerperal eclampsia. Whether this result is produced by its sedative influence upon the spinal cord or upon some other portion of the body we do not know, since the pathology of this condition is still but little understood. The dose to be efficacious must be far larger than that commonly employed for other purposes, 20 to 30 minims (1.3–2.0) of the fluid extract must be given hypodermically and followed by 5-minim doses every fifteen or twenty minutes until the pulse is reduced to approximately its normal rate. The drug is contraindicated in those cases of puerperal eclampsia which have a feeble circulation. The employment of veratrum as a circulatory sedative in the early stages of acute sthenic inflammation is much less popular at present than it has been in times past, perhaps because we now know that many of these inflammations are due to specific infections. It should not be employed in fevers, except in their earliest stages, in the presence of a full-bounding pulse, and this rule of course limits its application to the first 24 or 48 hours of most of the acute infectious inflammations.

Veratrum is sometimes employed in cases of palpitation of the heart with hypertrophy to relieve cerebral congestion in plethoric individuals, or those with a high arterial tension. In cases of high arterial tension associated with chronic contracted kidney it usually cannot be employed, because at the same time that it lowers blood-pressure it

also depresses the heart, which in many of these cases needs support. The drug does not lend itself to the treatment of children because of its tendency to produce nausea and vomiting in this class of patients, in whom aconite is usually much more serviceable.

Other Species.—It is not certain whether the California plant so-called is a variety of *Veratrum viride*, or a distinct species.

The genus *Veratrum* is credited with some 9 species, which, however, are not well differentiated. Most of them have a local repute as poisons, or are used medicinally. The "*V. parviflorum Mx.*," with quite an extended domestic medical history, is now classed as *Melanthium p.* (Mx.) Watson.

VERBENACEÆ.—The Verbena Family.

This is a family of about 70 genera and nearly 1000 species, mostly of tropical or warm temperate regions, and presenting nearly all habits of growth. Economic interest pertains chiefly to the ornamental features of such genera as *Verbena*, *Lantana*, *Callicarpa*, *Vitex*, and *Clerodendron*. A number of dye-stuffs are yielded by the family. *Tectona grandis* L. f. (*Theka g.*—Lam.) yields the celebrated teak-wood. Its leaves are used in India as an astringent and its flowers as a diuretic. From a medical point of view the family is unimportant, notwithstanding that the verbenas were formerly regarded as very important drugs, and a number of species of the family contain powerful alkaloids and glucosides and some valuable volatile oils.

Verbena or *Vervain*, as a drug, is usually understood to be the rhizome and roots of *V. hastata* L. (*V. paniculata* Lam.) the *American blue vervain*, *Purvain*, *Wild hyssop*, or *Simpler's joy*. The entire flowering plant is also employed. The plant is a native of central and eastern North America, being exceedingly common and abundant along roadsides and in waste places. It is a roughish-hairy perennial herb, reaching a height of about 1 M. (3–4 Ft.), sparingly branched above, bearing opposite leaves and panicled erect spikes of small, deep-blue flowers. The leaves are 5 to 10 Cm. (2–4 In.) long, lanceolate or lance-ovate, acute, sharply (usually doubly) serrate, and the base frequently hastate. The spikes often reach a length of 15 Cm. (6 In.), are rather stout, and densely flowered. The flowers are sessile, in bracts nearly as long as the calyx, which is 2.5 Mm. ($\frac{1}{10}$ In.) long, 5-lobed, the lobes broad and acute. The corolla is about 4 Mm. ($\frac{1}{6}$ In.) broad, somewhat unequally 5-lobed, pubescent below. The 4 included stamens are borne on the corolla. The fruit consists of 4 smooth nutlets, borne in the base of the calyx. The rhizome is short and woody, and bears numerous slender fibrous roots. The drug is bitter, astringent, and disagreeable. Its constituents have not been investigated, but its taste and activity are extracted by water. Vervain has properties somewhat resembling those of EUPATORIUM. It was formerly largely used as an antiperiodic, but this action is weak and uncertain. It is a nauseating expectorant and diaphoretic, and is emetic in large doses. An alcoholic preparation is a fairly good bitter tonic. As a diaphoretic and expectorant, the best preparation is a 5 per cent. infusion, in doses of 2 to 4 ounces. Of the fluidextract, the dose is 1 to 2 fluidrachms. *V. urticifolia* L., the *White* or *Nettle-leaved vervain*, is sometimes used instead, and has gained some repute in the treatment of rhus-poisoning. It grows with the other, but more sparingly. It is much more slender and branches more freely and widely. Its leaves are broader and thinner, and its spikes very slender, their smaller, white flowers not contiguous. A bitter glucoside has been extracted from it. *V. officinalis* L., of Europe, the ancient *Herba columbariæ* or *sanguinalis*, *Vervain* (*Berbine*) *Enchanter's herb*, *Herb of grace*, *Juno's tears* (E.); *Eisenkraut*, *Stahlkraut*, *Venusblut* (G.); *Vervaine officinelle* (Fr.) was in ancient times highly esteemed, and sometimes used as a tea-substitute. It somewhat resembles *V. hastata*, but is shorter and more branched. It has become considerably naturalized in the warmer parts of America. *V. littoralis* Kunth., of the Pacific coast of South America, is very similar and is similarly employed. *V. bracteosa* Mx. is employed in the central and western United States, *V. erinoides* Lam. in Peru, and *V. supina* L. in southern Europe and in China. In Mexico, *V. callicarpifolia* Kunth is used as a substitute for sage.

Oleum Verbenæ or *Verbena oil* is not the product of a true *Verbena*, but of *Lippia triphylla* (L'Herit.) Lyons (*Verbena t.*—L'Herit.; *Aloysia citriodora* Ort.; *Lippia citriodora* Kunth), the common *Lemon* or *Sweet verbena*, or *Herb Louisa*, *Vervenie odorante* (Fr.), introduced from Chili to garden cultivation. It is very similar to lemon-grass oil, containing about 35 per cent. of citral. It is soluble in 1 to 5 volumes of 90 per cent. alcohol, and has a specific gravity of 0.90. *Lippia*, of which genus a dozen species are used, is noted for its fragrant volatile oils. The drug *Lippia Mexicana* is the leaves of *L. dulcis* Trev. var. *dulcis*, of Mexico and Central America. These leaves are 2 to 4 Cm. (1 to 1½ In.) long, ovate, narrowed into the petiole, acute, serrate above, veiny and glandular-hairy. They have a peculiar, sweet, and very delightful aromatic odor and taste, and have been used as a stimulating expectorant. *L. graveolens* H. & B. is similarly employed in Mexico, where it is known as *Yerba dulce*. In the same country, *L. origanoides* Kunth. is used as a substitute for origanum. *L. nodiflora*

Mx. is employed in India under the names *Buccan*, *Vahkan*, *Ratolia*, etc. In Chili the last is called Yerba de la Santa Maria. In Brazil *L. pseudo-thea* Schauer is used as a substitute for tea, and its fruit is eaten.

Valerianodes Medic. (*Stachytarpheta* Vahl.) contains a number of species closely similar in their properties to Lippia, containing similarly fragrant volatile oils, as well as bitter principles.

Of *Lantana* L., a dozen species are employed like Verbena. *L. Camara* L. (*L. Antillana* Raf.; *L. mutabilis* Salisb., the common lantana of the garden, is known in the West Indies as *Wild sage* or *Sage-tree*, *Bahama tea* or *Cailleau*, is used as a substitute for tea, and is an antispasmodic. It contains the quinine-like alkaloid *lantanine*. In Brazil *L. brasiliensis* Link. is similarly employed, and contains the same alkaloid. *L. trifolia* L. is also used as a tea-substitute in the West Indies.

A number of species of *Callicarpa* L. are quite active diuretics and purgatives in tropical America. In the East Indies the leaves of *L. longifolia* Lam. are chewed as Betel leaves.

Agnus-Castus is the fruit of *Vitex Agnus-castus* L., the *Chaste-*, *Hemp-*, or *Monk's pepper-tree*, *Abraham's balm* or *Kausehlanum* (Ger.), of southern Europe and Asia. They contain the bitter body *viticin* or *castin*, but are valued for their pungent and acrid oil, on account of which they are employed as a general stimulant and antispasmodic, an emmenagogue, and aphrodisiac. *V. trifolia* L. and *V. leucoxylon* L. are used as antirheumatics in the East Indies. *V. altissima* L. and *V. pubescens* Vahl. are used in Ceylon as yellow dyes, under the name *Mail-Elon*. More than a dozen species of this genus are employed. The bark of *Premna Taitensis* Schauer, of the Fiji Islands and East Indies, mixed with the root of *Raphidophora Vitiensis* (Fam. *Araceæ*) formed the drug *Tonga*, which was recommended for neuralgia. Several other species of this genus are used in India as antispasmodics and diuretics, as are a number of species of the related genus *Gmelina*.

Under the name *Mancoa*, the root of *Avicennia officinalis* L. is employed as an emmenagogue and aphrodisiac.

Of *Clerodendron*, nearly a dozen species are employed in medicine. *C. neriifolium* Wall. (*Volkameria inermis* L. f., of India, *C. infortunatum* Gaert (*Khiri* or *Bhant*), *C. villosum* Bl. and *C. trichotomum* Thunb., are used as anthelmintics, as well as purgatives and diuretics.

VIBURNUM OPULUS, *U. S.*—Viburnum Opulus (Cramp-bark).

Cranberry-tree bark, E.; *Ecorce d'obier*, Fr.; *Wasserholderrinde*, G.

The dried bark of *Viburnum Opulus* L. (*V. trilobum* Marsh.—Fam. *Caprifoliaceæ*).

Cramp-bark is official in no other pharmacopœia.

Origin.—Viburnum Opulus, the Cranberry-tree, High-bush-cranberry, Guelder-rose, White dogwood, White, Red, Rose, or Water elder, Garter-tree, Pincushion-tree, Witch-hobble (E.), Wasserholder or Wasserschwelke (G.), Obier (Fr.), is a large shrub or small tree, distributed through most of the northern part of the north temperate zone, and represented in cultivation by the common Snow-ball tree of our lawns. The bark is collected chiefly in northern Europe.

Description.—In somewhat transversely curved pieces, occasionally in quills of variable length, 0.5 to 2 Mm. ($\frac{1}{50}$—$\frac{1}{12}$ In.) thick; outer surface grayish brown, longitudinally wrinkled, with large brown lenticels and brownish-black fruit-heads of a lichen; inner surface light brown, longitudinally striate; fracture uneven, fibrous; transverse sections showing several bands of bast fibres; odor slight; taste somewhat astringent and bitter.

The powder is yellowish gray and very fibrous, the fibres white and elongated. It contains numerous stone-cells, which are nearly all wall, and reach a diameter of 15 mikrons; rather few small starch-grains, a few red resin-cells, and a great variety of crystals of calcium oxalate.

Constituents.—So far as known, the constituents of cramp-bark are identical with those of *V. prunifolium*, though there is only a third as much resin.

Pharmaceutical Preparation.—Fluidextract of Viburnum Opulus, U. S. P.

Fig. 469.

Viburnum opulus, outer and inner surfaces (Nat.).

Action and Uses.—Viburnum opulus is considered to possess in a lesser degree the properties of viburnum prunifolium. It is recommended as an antispasmodic in asthma, hysteria, puerperal convulsions, and dysmenorrhœa. It may be given in the dose of 20 to 60 grains (1.30–4 Gm.), but is usually used in form of the fluidextract.

VIBURNUM PRUNIFOLIUM, *U. S.*—Black Haw.

Nanny-berry, Sheep-berry, Stag-bush.

The dried bark of the root of *Viburnum prunifolium* L. or of *V. Lentago* L. (Fam. *Caprifoliaceæ*).

Viburnum prunifolium is not recognized in any other pharmacopœia.

Origin.—Both species are large shrubs or small trees of eastern and central North America, and are very abundant, especially the first named, in hedge-rows and borders of forests, having similar habits to those of the hawthorn in England. They are densely branched, opposite-leaved, and many of the branches bear thorny branchlets. The flowers are very abundant, in terminal corymbs, white, very showy and fragrant in late spring. They are succeeded by small flattish-oval drupes which, after frost, are purple black, glaucous, sweet and somewhat edible. The second named is distinguished from the first by its ovate or oval, long-acuminate (instead of obovate and obtusish) leaves, and its sessile or nearly sessile corymbs. Its leaves, corymbs, flowers, and fruits are somewhat larger than those of the former.

FIG. 470.

a *b* *c*

Viburnum prunifolium, inner and outer surfaces: *a*, young stem-bark; *b*, trunk-bark; *c*, root-bark (Nat.).

Description.—In irregular or quilled pieces, rarely exceeding 4 Mm. ($\frac{1}{6}$ In.) thick; externally dingy brown, shallowly fissured and slightly scaly; inner surface rust brown and having short, broad, oblique striæ; fracture weak, short, and uneven, the inner layer pale brown, the middle rust brown, the outer dark brown; odor slight, peculiar; taste bitter, that of the root-bark very bitter, somewhat astringent.

The powder is of a darker color than that of cramp-bark. Its bast-fibres are fewer and much shorter, and its stone-cells far more numerous and several times larger. Red resin-cells are much more abundant. Otherwise, it is much like that of cramp-bark.

Bark from branches or young stems is externally very dark purple, somewhat glossy, and bears scattered warts, which increase in number as it grows older. Clusters of minute black specks are often seen. That from old stems is blackish, often with gray patches, and is roughly fissured and more or less scaly. The inner surface is whitish or pale brown, and its striæ short and broad, often resembling elongated blisters. In the powder of the stem-bark bast-fibres are much more numerous than in that of the root-bark, though never so conspicuous as in that of cramp-bark.

It appears as though a large part of the bark collected in the Southern States must come from *V. rufotomentosum* Small, a species until recently confused with *V. prunifolium*. This bark has not been studied, but that supposed to be referable to it is thicker, darker, and softer, and has a very strong and different odor. It may be equal, or even superior, to the other, but this is conjectural.

Constituents.—With starch, a little tannin, much ash, and about 2.5 per cent. of resin, Viburnum contains a bitter, water-soluble glucoside, which has not been studied, but is probably the source of the valerianic acid which appears to be the important constituent.

Pharmaceutical Preparation.—Fluidextract of Viburnum Prunifolium, U. S. P.

Action and Uses.—The virtues attributed to viburnum prunifolium are as feeble as they are numerous. It has been used as a nervine, astringent, diuretic, and tonic and is said to possess a powerful influence as an uterine sedative and preventive of abortion. It is an ingredient of many proprietary preparations, vaunted as uterine sedatives, but the experience of most physicians fails to justify a belief in the qualities claimed for it. The dose of viburnum prunifolium is from 20 to 60 grains (1.30–4 Gm.), given in fluidextract or decoction.

Other Species.—The genus *Viburnum* L. contains more than 100 species of the north temperate zone, and extending into subtropical regions. More than a dozen species are employed medicinally. A number of species grow in the *V. prunifolium* region, and it is not unlikely that some are collected for it; indeed, we have seen in commerce what we believed to be the bark of *V. dentatum*. It is in the form of strips, like cramp-bark, but darker externally. *V. fœtidum*, Wall., cultivated in India under the name *Narvil* or *Naruval*, is used for the same purposes as *V. prunifolium*. The bark of *V. Lantana* L. (*V. tomentosum*, Lam.), Giddy-berry (E.), Schwindelbeere (Ger.), of Europe, is said to be vesicant. The berries of *V. Tinus* L. (*V. laurifolius* Borkh.), *False Laurel-berry* or *Laurierthym*, of the Mediterranean region, are purgative. The flowers of the Chinese species, *V. odoratissimum* Ker. (*V. Chinensis* Zeyh) are used as a tea substitute.

VINA MEDICATA.—Medicated Wines.

Vins medicinaux, Œnolés, Fr.; *Medicinische Weine*, G.

Medicated wines are preparations analogous to tinctures, but differ from them in the menstruum, which contains a much smaller and a somewhat variable quantity of alcohol and a certain proportion of extractive matter and acid potassium tartrate. The menstruum directed for the medicated wines is either dry white wine (Fr. Cod., P. G.), a mixture of white wine and alcohol (U. S., Fr. Cod.), sherry wine (Br., P. G.), dry red wine (U. S.), or Lunel, Grenache, Malaga, and other wines (Fr. Cod.). Since even the strongly alcoholic official wines cannot be kept unaltered for an indefinite period if exposed to the air, the medicated wines, which necessarily contain various principles subject to gradual decomposition, should be kept in well-stoppered bottles.

The presence of appreciable quantities of tannin in wine is decidedly objectionable if the wine is to be used in connection with iron and other metallic salts; moreover, tannin is incompatible with alkaloids, and hence wine not deprived of its tannin should never be used as a menstruum for alkaloidal drugs. The process of detannating wine is a very simple operation. One-half ounce of gelatin in No. 40 powder is added to a gallon of wine, and the whole agitated occasionally during 24 or 48 hours; then filter. The operation should be carried out during cold weather or in a cold apartment, as heat will cause the gelatin to dissolve, and maceration must be continued until a small portion of the wine shows no darkening of color upon addition of a few drops of ferric chloride solution.

VINUM ALBUM, *U. S.*—White Wine.

Vinum generosum album.—*Vin blanc*, Fr.; *Weisswein*, G.; *Vino blanco*, Sp.

An alcoholic liquid made by fermenting the unmodified juice of the fresh fruit of *Vitis vinifera*, Linné (Fam. Vitaceæ), freed from seeds, stems, and skins, and subjected to the usual cellar treatment for fining and aging. When white wine is prescribed without further specification, it is recommended that dry white wine of domestic production be employed. White wine should be preserved in well-closed, full casks or in well-stoppered bottles in a cool place.—U. S.

Origin.—American wines are mostly obtained from the fruit of cultivated varieties of *Vitis Labrusca*, Linné, and more particularly from Catawba, Concord, and Isabella grapes. The Clinton grape is a variety of *V. æstivalis*, Michaux; the Delaware grape is derived from *V. cordifolia* or *V. riparia*, Michaux; and the Scuppernong grape from *V. vulpini*, Linné. The European grape was introduced into California at an early

period, and large quantities of wine are now manufactured from the different varieties. All European wines are prepared from the fruit of *Vitis vinifera*, Linné, which is a native of Western Asia and has been cultivated for many centuries; it is not unlikely that this species originated from two or three different plants, supposed by some botanists to be indigenous to India, and by others to be still found in the wild state in Eastern countries and in Southern and Central Europe.

Manufacture of Wine.—In addition to grape sugar and acid potassium tartrate, vegetable albumen, glutinous matter, pectin, and various extractive matters are found in the juice of grapes, and occasionally racemic acid, either in the free state or partly combined with bases. Besides tartrates, the saline constituents are potassium sulphate, sodium chloride, calcium phosphate, magnesia, alumina, and silica. The relative amount of these principles varies considerably, depending on the nature of the soil and on atmospheric conditions during the growth and ripening of the fruit, when the free acid is gradually diminished and the sugar considerably augmented in quantity. The sugar varies in amount between 12 and 30 per cent., the larger quantity being produced in warm climates. It is obvious from this that the treatment of the grape-juice for the production of wine must vary under different circumstances and in different countries. The grapes are crushed and the juice fermented in the presence of the husks, or the juice, called *must*, is fermented by itself, in which case a light-colored wine is obtained. Red wines are made by fermenting with husks and seeds, called the *marc*, of red or purple grapes. In a short time after the must has been pressed, fermentation commences, and continues for two or three weeks, when the liquid becomes somewhat clear, and is removed from the precipitate into another vessel, where a slow fermentation, called the after-fermentation, proceeds for several weeks or months, requiring the occasional removal of the liquid from the sediment formed, until it is fit to be transferred into casks, where it is allowed to "ripen." The best wines are usually bottled some time after they have become perfectly clear, the complete clarification being effected by gelatin, which, in combining with the tannin present, forms an insoluble compound, carrying down with it all the traces of yeast and other matters held in suspension. The "bouquet" of wine is much improved after bottling, and red wines, which do not contain a large amount of tannin, become darker, while wines rich in tannin form a deposit in the bottle and become lighter in color.

In the presence of the numerous constituents of grapes odorous principles are generated during fermentation, to which wines owe their peculiar aroma or bouquet. If the must contains a moderate quantity of sugar, this is entirely or nearly decomposed into alcohol and carbon dioxide, resulting in a dry wine. But in a strongly saccharine must fermentation ceases before the sugar is completely consumed, and the product is a sweet wine (*vin de liqueur*, Fr.). In some cases the amount of sugar in the juice is increased by exposing the cut ripe grapes for some time to the sun until a portion of the water has evaporated, or by concentrating a portion of the juice before fermentation. As the alcohol increases during the fermentation of the must, the acid potassium tartrate becomes less soluble and is gradually deposited, the deposition continuing for some time after the storing of the wine in casks.

If wine is bottled before it has undergone the after-fermentation, a sparkling wine will be obtained. The fermentation will slowly proceed in the bottle, which is placed upside down, so that the precipitate which forms may settle in the neck, and may be finally withdrawn by carefully removing the stopper and quickly replacing it. The effervescence of sparkling wines is produced by the carbon dioxide confined in the bottle.

Properties.—The U. S. Pharmacopœia describes white wine as a pale, amber- or straw-colored liquid, having a pleasant odor free from yeastiness, and a fruity, agreeable, slightly spirituous taste without excessive sweetness or acidity. Its specific gravity at 15.6° C. (60° F.) should be not less than 0.990 nor more than 1.010.

Sherry wine (*Vinum Xericum*, Br.) has a rather deep amber color, an agreeable vinous odor, and a warm and very slightly acid taste. Its specific gravity range is between 0.978 and 0.995, and its average alcoholic strength 20.34 volumetric per cent.; the sugar and extractive averages 3.27 (highest 5.3) per cent. Similar wines are produced in various parts of Spain, Portugal, the Canaries, and Madeira, several of which are met with in our commerce. Lisbon wine has a density of about 0.990, and contains 19 or 20 per cent. of alcohol. Teneriffe wine closely resembles the preceding in proper-

ties. A stronger wine is Madeira, which usually contains between 19 and 22 per cent. of alcohol; it has a different somewhat nutty flavor.

Wines of similar strength in alcohol are also made in Italy (Marsala), Greece (*vino santo*), and the Cape Colony (Constantia). Southern France produces wines containing 14 to 16 per cent. of alcohol, of which those of Lunel and Grenache are ordered by the Codex. Burgundy wines are of about the same strength. Very sweet wines, rich in alcohol are, among others, Tokay (Hungary), Lachrymæ Christi (Italy), and Malaga (Spain).

The white Rhenish wines are known here as hock (from Hochheimer). They have a more acidulous taste than the preceding wines, from the presence of acid potassium tartrate and the nearly total absence of sugar. They are of a pale-yellow color, and usually contain between 8 and 10 per cent. of alcohol. Moselle wine is nearly of the same strength. The French wines, both white and red, are required to contain about 10 per cent. of alcohol (Fr. Cod.).

The white wines of the Mississippi and Ohio Valleys and the California wines resemble those of Central and Southern Europe in appearance, flavor, and alcoholic strength; the weaker varieties of the latter, which are known as California hock, have not the fine bouquet of the better qualities of Rhenish wines, but the quality of American wines has considerably improved of late years.

The sparkling champagne wines contain between 10 and 12 per cent. of alcohol.

Constituents.—The principal constituents of all wines are water and alcohol. The amount of the latter present in different wines has been given above. The acidulous taste of wine is due to acid potassium tartrate, and small quantities of acetic acid are met with in old wines, resulting from the spontaneous oxidation of alcohol. A somewhat larger proportion of acetic acid is usually present in the wine of the Eastern section of the United States. The amount of sugar varies considerably; while the weaker dry wines contain none or but very little, it is found in sherry to the extent of from 1 to 5 per cent., increases in champagne sometimes to 5 or 6 per cent., in port wine to 6 or 7 per cent., and in the sweet wines, like Malmsey Madeira, to 11 or 15 per cent. or more. The "body" of wine has been ascribed by Fauré to a principle which he named œnanthin, and which is probably of the nature of gum or dextrin. Tannin seems to be present in all wines—in minute proportion in the white, and in larger proportion in the red wines. The coloring-matter of wine varies for causes stated above; the color of red grapes is not soluble in water, but is extracted during fermentation as the alcohol increases. The aroma of wine is doubtless due to the presence of various compound ethers formed in the juice while fermenting. These exist in very minute quantities, and have for this reason not been accurately examined; but the following have been stated to contribute to the aromatic odor of wine: acetic, butyric, caprylic, caproic, œnanthic, pelargonic, capric, and propionic ethers, besides aldehyde, acetal, and probably other compounds. The inorganic constituents of wine are the same as those of grape-juice, except that calcium tartrate and the greater portion of acid potassium tartrate have been deposited; the ash varies between about 0.1 and 0.5 per cent.

The U. S. Pharmacopœia not only permits, but encourages, the use of native wines, provided they be pure and contain between 7 and 12 per cent. by weight of absolute alcohol. From causes explained before, the composition of wines made from the same variety of grape grown in different localities, or from different vintages in the same locality, must be expected to vary to some extent; every quantitative analysis of wine, therefore, refers only to the sample examined.

Changes.—Like other weak alcoholic liquids, wine is apt to undergo acetic fermentation, which is prevented by excluding atmospheric oxygen. Mucous fermentation causes wine to become ropy; white wines are subject to this change more than red wines, caused by the presence of insufficient tannin in the must for precipitating all the albuminoids. Some wines, like Burgundy, are liable to acquire a bitter taste, and occasionally wine becomes mouldy. Scrupulous cleanliness of the vessels in which wine is kept and exclusion of air will prevent most of these changes.

Tests.—With the exception of the U. S. P., none of the pharmacopœias give any tests for determining the quality of wine, which is directed to be ascertained as follows: "If a portion of white wine be evaporated, the residue, when dried during 12 hours on a water-bath, should amount to not less than 1.5 nor more than 3 per cent.; this residue ignited at a low temperature and burned gradually to whiteness, moistened with a small

portion of ammonium carbonate test-solution, and again carefully ignited, should weigh not less than 0.14 Gm. nor more than 0.26 Gm. for each 100 Cc. of white wine tested. To neutralize 50 Cc. of white wine should require not less than 3 nor more than 5.2 Cc. of normal potassium hydroxide solution (limit of free acid), litmus test-solution being used as indicator. If 10 Cc. of white wine be diluted with an equal volume of water, and treated with 5 drops of ferric chloride test solution, only a faint greenish-brown color should make its appearance (absence of more than traces of tannic acid). If 75 Cc. of white wine be acidified with 5 Cc. of diluted sulphuric acid (1 in 3), and thoroughly shaken in a separator with a mixture of equal parts of petroleum benzin and ether, and if the solvent, after separation, be transferred to a porcelain dish, allowed to evaporate spontaneously, and the residue dissolved in 3 Cc. of water, the solution should not have a sweet taste (absence of saccharin), nor should it give a violet color upon the addition of a diluted solution of ferric chloride (1 in 200) (absence of salicylic acid). Tested by the following method white wine should be found to contain not less than 7 nor more than 12 per cent. by weight (equivalent to from 8.5 to 15 per cent. by volume) of absolute alcohol: Take the specific gravity (to four decimals) of a sufficient portion of the white wine carefully measured at the temperature of 15.6° C. (60° F.), evaporate the wine in a tared dish to one-third of its original weight, cool, and add water until the liquid measures its original volume at 15.6° C. (60° F.); then take the specific gravity (to four decimals) again. The difference between the two specific gravities deducted from 1.0000 corresponds to the specific gravity of an alcohol containing the same percentage of absolute alcohol, by weight or volume, as the wine under examination, the corresponding percentage being ascertained by referring to the alcohol tables."—U. S.

Action and Uses.—The physiological action of wine depends almost entirely upon the alcohol contained (see ALCOHOL). Consumed in moderate quantity it is devoid of injurious effects, but its habitual use in excessive amounts tends to induce gout, cirrhotic conditions of the liver and kidneys, sclerosis of the blood-vessels, nervous affections, etc. These results do not so frequently follow over-indulgence in the light, dry wines as in the strong, sweet wines. White wine contains a much smaller per cent. of tannin than does red wine, and for this reason is more readily absorbed from the stomach and is preferred when a rapid, stimulating effect is desired. On the other hand, red wine is better adapted in the convalescence from acute diseases and in states of general debility. Wine may be employed in the treatment of disease when an alcoholic stimulant is deemed advisable, but because it is comparatively weak in alcohol it is not so well adapted to grave, adynamic fevers in adult males as it is in females, children, and the aged. The indications for the use of wine in typhoid fever and in other febrile affections which assume the typhoid state are weakness of the first sound of the heart, low, muttering delirium, stupor, carphology, etc.; its employment in large quantity in typhus fever and in some cases of tetanus has been followed by happy results. Wine is an admirable remedy to be used in the convalescence from exhausting fevers, acting as it does as a mild exhilarant, an aid to digestion, and a tonic to the nervous system. Of the white wines, a pure sherry, if such can be obtained, is to be preferred for the convalescing patient on account of its slight acidity and freedom from a large quantity of saccharine matters. The sweet wines are not so serviceable, as they are apt to derange digestion. Champagne, aside from its stimulating qualities, will often be found of great value to allay nausea and irritability of the stomach in the low states of fevers and following ether-anæsthesia. A useful method in which to administer wine is in wine whey, prepared by adding to 1 pint of boiling milk from 2 to 8 ounces of wine, straining off the whey without pressure, and sweetening it to suit the taste.

VINUM ANTIMONII, *U. S.*—Wine of Antimony.

Vinum antimoniale, Br.; *Vinum stibiatum*, P. G.—*Antimonial wine*, E.; *Vin émétique, Vin antimonié, Vin stibié*, Fr.; *Brechwein*, G.

Preparation.—Antimony and potassium tartrate, 4 Gm.; boiling distilled water, 65 Cc.; alcohol, 175 Cc.; white wine, a sufficient quantity to make 1000 Cc. Mix the alcohol with 725 Cc. of white wine. Dissolve the antimony and potassium tartrate in the boiling distilled water, and add the solution to the mixture. When the liquid is

cold filter it through paper, and add enough white wine, through the filter, to make the product measure 1000 Cc.—*U. S.*

To make 1 pint of wine of antimony use 29¼ grains of antimony and potassium tartrate, 1 fluidounce of boiling distilled water, 2¾ fluidounces of alcohol, and sufficient white wine to make 16 fluidounces of solution.

Each Cc. of finished product contains 0.004 Gm. (or 1 fluidrachm, about ¼ grain) of tartar emetic.

Nearly the same proportions are the following: Tartarated antimony, 40 grains; boiling distilled water, 1 fluidounce; sherry, sufficient to make 1 pint (imperial).—*Br.* Tartar emetic, 1 part; sherry wine, 249 parts.—*P. G.*

If made with good wine and judiciously preserved antimonial wine will keep unaltered for a long time.

Uses.—Wine of antimony may be employed whenever it is desired to administer tartar emetic (see ANTIMONII TRIOXIDUM). Its dose as an expectorant and circulatory sedative is from 10 to 30 minims (0.60–2 Cc.). As an emetic from ½ to 1 drachm (2–4 Cc.) may be given to children and 1 to 2 drachms (4–8 Cc.) to adults.

VINUM AURANTII, *Br.*—Orange Wine.

Wine made by the fermentation of a saccharine solution to which the fresh peel of the bitter orange has been added.—*Br.*

It is a vinous liquid, having a gold-sherry color and a taste and aroma derived from the bitter orange-peel. It contains about 10 or 12 per cent. of alcohol, and is but slightly acid to test-paper.

Uses.—This agreeable, aromatic wine is used solely as a flavoring ingredient of mixtures.

VINUM CAMPHORATUM, *P. G.*—Camphorated Wine.

Vin camphré, Fr.; *Kampherwein*, G.

Preparation.—Camphor, 1 part; alcohol, 1 part; mucilage of acacia, 3 parts; white wine, 45 parts. Dissolve the camphor in the alcohol, slowly incorporate with the mucilage, constantly stirring, and finally add the wine in the same manner.—P. G.

Camphorated wine is whitish and turbid, and should be shaken before using.

Uses.—Camphorated wine is an efficient preparation for the internal administration of camphor, especially in cholera and choleraic diarrhœa. Its dose for a child from 2 to 6 years of age is about 1 drachm (4 Cc.). Adults may take from 4 to 8 drachms (16–80 Cc.).

VINUM CHINÆ, *P. G.*—Wine of Cinchona.

Vin de quinquina, Fr. Cod.; *Vinum cinchonæ.*—*Œnolé de quinquina*, Fr.; *Chinawein*, G.

Preparation.—Red cinchona, in coarse powder, 40 parts; gelatin, 1 part; sugar, 100 parts; tincture of bitter orange peel, 2 parts; sherry wine, 1000 parts. Dissolve the gelatin in 10 parts of hot water and add the sherry wine to the warm solution. Now add the cinchona and allow maceration to go on with frequent agitation for 8 days; strain and express, and in the liquid dissolve the sugar and add the tincture of bitter orange peel. Set aside for 2 weeks in a cool place and filter.—P. G.

Uses.—This is an agreeable, aromatic, bitter wine, useful as a stimulant to the appetite and digestion. The dose is from 2 to 4 drachms (8–16 Cc.).

VINUM COCÆ, *U. S.*—Wine of Coca.

Vinum erythroxyli.—*Vin de coca*, Fr.; *Cocawein*, G.

Preparation.—Fluidextract of coca, 65 Cc.; alcohol, 75 Cc.; sugar, 65 Gm.; red wine, a sufficient quantity to make 1000 Cc. Dissolve the sugar in 500 Cc. of red wine, add the alcohol and fluidextract of coca, and enough red wine to make the liquid measure 1000 Cc. Set the mixture aside for 2 days; then filter through paper, in a well-covered funnel.—U. S.

To make 1 pint of wine of coca, dissolve 475 grains of sugar in 8 fluidounces of red wine, add 1 fluidounce and 58 minims of alcohol and 1 fluidounce and 20 minims of fluidextract of coca, and finally enough red wine to bring the volume up to 16 fluidounces. After 2 days filter.

Each Cc. of wine of coca represents 0.065 Cc., or 1 fluidrachm about 4 minims of fluidextract of coca.

Uses.—This preparation combines the stimulant effects of coca with those of the menstruum. It has become very popular with the laity as a remedy in mental and physical fatigue. It may be administered whenever the effects of the drug are desired. The dose is from 2 to 8 drachms (9–30 Cc.).

VINUM COLCHICI, *Br.*—Colchicum Wine.

Vinum colchici radicis; Vin de bulbe de colchique, Fr. Cod.—*Wine of colchicum root*, E.; *Œnolé de bulbe de colchique*, Fr.; *Zeitlosenknollenwein*, G.

Preparation.—Colchicum corm, in No. 20 powder, 4 ounces; sherry, 1 imperial pint. Macerate for 7 days with occasional agitation, express and filter.—Br.

The French Codex directs that 100 Gm. of fresh colchicum bulbs be macerated with 1000 Gm. of strong wine (vin de Grenache).

Uses.—This preparation, no longer official in the U. S. P., is used as is the VINUM COLCHICI SEMINIS (see below). The dose is from 10 to 30 minims (0.60–2 Cc.).

VINUM COLCHICI SEMINIS, *U. S.*—Wine of Colchicum Seed.

Vinum colchici, P. G.—*Vin de semence de colchique*, Fr.; *Zeitlosensamenwein*, G.

Preparation.—Fluidextract of colchicum seed, 100 Cc.; alcohol, 150 Cc.; white wine, 750 Cc. Mix and set aside for 2 days; then filter.—U. S.

To make 1 pint of the wine mix 1 fluidounce and 288 minims of fluidextract of colchicum seed, 2 fluidounces and 172 minims of alcohol, and sufficient white wine to bring the volume up to 16 fluidounces.

The German Pharmacopœia directs 1 part of coarsely powdered colchicum seed to be macerated for 8 days with 10 parts of sherry wine.

Uses.—In this form colchicum is most largely administered. The strength of the preparation has been decreased one-third. The dose is from 20 to 60 minims (1.30–4 Cc.).

VINUM CONDURANGO, *P. G.*—Wine of Condurango.

Vin de condurango, Fr.; *Condurangowein*, G.

Preparation.—Condurango bark, finely cut, 1 part; sherry wine, 10 parts. Macerate for 8 days, express, and filter.—P. G.

Uses.—Condurango wine is a useful stimulant to the stomach, and in moderate quantity an aid to digestion; recommended especially in gastric cancer. The dose is from 1 to 4 drachms (4–16 Cc.).

VINUM DIGITALIS COMPOSITUM.—Compound Wine of Digitalis.

Vin de digitale composé de l'Hôtel-Dieu, Fr. Cod.; *Vinum diureticum. Trousseau's diuretic wine*, E.; *Vin de Trosseau*, Fr.; *Trosseauscher Wein, Zusammengesetzter Digitaliswein*, G.

Preparation.—Digitalis, in coarse powder, 5 Gm.; squill, bruised, 7.50 Gm.; juniper berries, bruised, 75 Gm.; potassium acetate, 50 Gm.; white wine, 900 Gm.; alcohol, 100 Gm. Mix the alcohol and white wine and pour the mixture over the digitalis, squill, and juniper berries, contained in a vessel provided with a good stopper; macerate for 10 days with occasional agitation. Strain with expression, and dissolve the potassium acetate in the expressed liquid; finally filter.—Fr. Cod.

Uses.—Compound wine of digitalis is designed as a diuretic to be used in dropsy due to chronic renal or cardiac disease. The dose is from 2 to 4 drachms (8–16 Cc.).

VINUM ERGOTÆ, *U. S.*—Wine of Ergot.

Vin de seigle ergoté, Fr.; *Mutterkornwein*, G.

Preparation.—Fluidextract of ergot, 200 Cc.; alcohol, 50 Cc.; white wine, 750 Cc. Mix. Set the mixture aside for 2 days; then filter through paper, in a well-covered funnel.—U. S.

To make 1 pint of wine of ergot, mix 3 fluidounces and 96 minims of fluidextract of ergot with 6½ fluidrachms of alcohol and sufficient white wine to bring the volume up to 16 fluidounces.

Each Cc. of wine of ergot represents 0.20 Gm.; of each fluidrachm about 12 grains of ergot.

Uses.—The strength of this wine has been increased from 15 to 20 per cent. of ergot. It is less frequently employed than the other preparations of the drug. The dose is from 1 to 4 drachms (4–16 Cc.).

VINUM FERRI, *U. S.*—Wine of Iron.

Vinum ferri citratis, Br., U. S., 1890; *Vin chalybé*, Fr. Cod. *Vinum chalybeatum.*—*Wine of iron citrate*, E.; *Vin ferrugineux, Œnolé ferrugineux*, Fr.; *Eisenwein*, G.

Preparation.—Iron and ammonium citrate, 40 Gm.; tincture of sweet orange peel, 60 Cc.; syrup, 100 Cc.; white wine, a sufficient quantity to make 1000 Cc. Dissolve the iron and ammonium citrate in 700 Cc. of white wine. Add to this the tincture of sweet orange peel and the syrup, and, lastly, enough white wine to make the product measure 1000 Cc. Set the mixture aside for several days, then filter, and pass enough white wine through the filter to restore the original volume.—U. S.

To make 1 pint of wine of iron dissolve 292 grains of iron and ammonium citrate in 11 fluidounces of white wine; add 1½ fluidounces of tincture of sweet orange peel, 1¾ fluidounces of syrup, and sufficient white wine to make 16 fluidounces of solution.

The British Pharmacopœia directs wine of iron citrate to be prepared by dissolving 160 grains of iron and ammonium citrate in sufficient orange wine to form 1 imperial pint (20 fluidounces) of solution.

Since the title of this preparation has been changed in the recent revision of the U. S. Pharmacopœia, it must be borne in mind that a different preparation is known by the same name, *Vinum Ferri—Wine of Iron*, in the British Pharmacopœia. The latter is made by placing iron wire, 1 ounce, in a closed vessel containing 1 imperial pint of sherry wine, in such a way that the wire is almost but not entirely immersed in the wine; the mixture is allowed to stand for 30 days with frequent agitation, the stopper being occasionally removed to allowed the escape of the liberated hydrogen. It is finally filtered. The amount of iron taken up depends wholly on the acidity of the wine, and in a good preparation will average about $\frac{1}{5}$ per cent.

The chalybeate wine of the French Codex is a much weaker preparation, containing in 1000 parts only 5 parts of iron and ammonium citrate.

Uses.—This is a mild chalybeate remedy, useful in chlorotic anæmia when the stomach is irritable. Its dose is from 1 to 4 drachms (4–16 Cc.).

VINUM FERRI AMARUM, *U. S.*—Bitter Wine of Iron.

Vinum chinæ ferratum.—Vin de quinquina ferrugineux, Fr.; *Chinaeisenwein*, G.

Preparation.—Soluble iron and quinine citrate, 50 Gm.; tincture of sweet orange peel, 60 Cc.; syrup, 300 Cc.; white wine, a sufficient quantity to make 1000 Cc. Dissolve the soluble iron and quinine citrate in 500 Cc. of white wine. Add to this the tincture of sweet orange peel and the syrup, and, lastly, enough white wine to make the product measure 1000 Cc. Set the mixture aside for several days, then filter, and pass enough white wine through the filter to restore the original volume.—U. S.

To make 1 pint of bitter wine of iron dissolve 365 grains of soluble iron and quinine citrate in 8 fluidounces of white wine; add 1½ fluidounces of tincture of sweet orange peel, 5 fluidounces of syrup, and sufficient white wine to make 16 fluidounces of solution.

Each Cc. of the finished product contains 0.05 Gm. (or 1 fluidrachm, nearly 3 grains) of the soluble citrate of iron and quinine.

Uses.—Bitter wine of iron is an efficient tonic in convalescence from exhausting fevers or in cases of general debility. The dose is from 1 to 4 drachms (4–16 Cc.).

VINUM IPECACUANHÆ, *U. S.*, *Br.*, *P. G.*—Wine of Ipecac.

Vin d'ipécacuanha, Fr.; *Brechwurzelwein*, G.

Preparation.—Fluidextract of ipecac, 100 Cc.; alcohol, 100 Cc.; white wine, 800 Cc. Mix. Set the mixture aside for 2 days; then filter through paper in a well-covered funnel.—U. S.

To make 1 pint of wine of ipecac mix 1 fluidounce and 288 minims each of fluidextract of ipecac and alcohol with sufficient white wine to bring the volume up to 16 fluidounces.

The British Pharmacopœia directs that 1 fluidounce of liquid extract of ipecac be mixed with 19 fluidounces of sherry wine, and the mixture filtered after 48 hours.

Wine of ipecac represents in each Cc. the active virtues of 0.10 Gm., or in each fluidrachm of about 6 grains of ipecac root. The German preparation is of about the same strength, being made by macerating 1 part of finely cut ipecac root in 10 parts of sherry wine.

Uses.—Wine of ipecac may be employed whenever the emetic, expectorant, diaphoretic, or other virtues of the drug are desired (see IPECACUANHÆ). As an emetic, its dose in the adult is about 1 ounce (30 Cc.); in an infant 2 or 3 years of age, 1 drachm (4 Cc.), repeated every 15 minutes until it has produced vomiting. Its dose as an expectorant and diaphoretic is from 10 to 30 minims (0.60–2 Cc.).

VINUM OPII, *U. S.*—Wine of Opium.

Vinum opii compositum, Fr. Cod.; *Tinctura opii crocata*, P. G.; *Laudanum liquidum Sydenhami.—Sydenham's laudanum*, E.; *Laudanum de Sydenham, Vin d'opium composé*, Fr.; *Safranhaltige Opiumtinktur*, G.

Preparation.—Powdered opium, 100 Gm.; Saigon cinnamon, in No. 60 powder, 10 Gm.; cloves, in No. 30 powder, 10 Gm.; alcohol, 150 Cc.; white wine, a sufficient quantity to make 1000 Cc. Mix the alcohol with 850 Cc. of white wine. Macerate the opium, Saigon cinnamon, and cloves in a stoppered container, in a moderately warm place, with 750 Cc. of this menstruum, during 7 days, with occasional agitation; then filter through purified cotton, in a well-covered funnel, returning the first portions until the filtrate passes perfectly clear, and finally pass enough menstruum through the residue to make the liquid measure 1000 Cc.—U. S.

To make 1 pint of wine of opium use 730 grains of powdered opium and 73 grains each of cloves and Saigon cinnamon; macerate for 7 days with 12 fluidounces of the menstruum (alcohol 15 volumes, white wine 85 volumes). After filtration pass enough menstruum through the filter to bring the volume up to 16 fluidounces.

Each Cc. represents 0.1 Gm. (or 1 fluidrachm—about 5.7 grains) of opium.

The wine has been replaced in the P. G. by a diluted alcohol. The other formulas are: Opium, 200; saffron, 100; Ceylon cinnamon, 15; cloves, 15; wine, 1600 Gm.—Fr. Cod. Opium, 30; saffron, 10; Chinese cinnamon, 2; cloves, 2; alcohol (68½ per cent.), and water, 140 parts.—P. G. That of the French Codex, being made with a sweet wine, is denser (sp. gr. 1.05 to 1.07) than the other preparations. On keeping, this wine deposits some extractive matter and occasionally some narcotine.

LAUDANUM DE ROUSSEAU, Fr. Cod., contains about one-fourth its weight of opium, and is therefore considerably stronger than the preceding; it is made by fermenting a mixture of opium, 200 Gm.; honey, 600 Gm.; water, 3 liters; and beer-yeast, 40 Gm.; the filtered liquor is then evaporated to 600 Gm. and mixed with alcohol (sp. gr. 0.913) 200 Gm.

Uses.—Wine of opium is considered to be superior to the tincture of opium as an internal remedy, because it is less apt to cause nausea. Its dose is from 5 to 20 minims (0.30–1.30 Cc.).

VINUM QUININÆ, *Br.*—Quinine Wine.

Vin de quinine, Fr.; *Chininwein*, G.

Preparation.—Quinine hydrochloride, 20 grains; orange wine, 1 imperial pint. Dissolve; set aside; filter if necessary.—Br.

This is a weak solution of quinine, containing 1 grain of the salt in each fluidounce.

Uses.—The dose of this feeble, bitter tonic wine is from 4 to 8 drachms (16–30 Cc.).

VINUM RUBRUM, *U. S.*—Red Wine.

Vin rouge, Fr.; *Rothwein*, G.; *Vino tinto*, Sp.

An alcoholic liquid made by fermenting the unmodified juice of the fresh, colored fruits of Vitus vinifera (Fam. *Vitaceæ*) in presence of their skins, and subjected to the usual cellar treatment for fining and aging. When red wine is prescribed without further specification, it is recommended that a dry red wine of domestic production be employed. Red wine should be preserved in well-closed, full casks or in well-stoppered bottles in a cool place.—U. S.

Origin and Description.—The fruits of most cultivated varieties of the American grapevines and of numerous varieties of the European species have either an amber color or are purple, dark-blue, or nearly black. The juice of these grapes is colorless or nearly so, and if fermented alone yields a white wine, but if fermented with the pericarp or skins the coloring matter of the latter is extracted, and the wine has a red color, varying in shade with the variety of grapes, with the quantity of skins, the length of time they have been in contact with the fermenting liquid, and with the amount of alcohol and acid present. Although many white wines contain tannin, taken up from the pericarp of the fruit or from the seeds, the quantity is usually minute as compared with that present in red wines, and which comes from the same sources. It is obvious, therefore, that red wine agrees in properties and composition with white wine, except so far as these are modified by the red coloring matter and the tannin, the most striking differences being the deep-red color, the distinctly astringent taste, and the effect produced by alkalies, ferric chloride, lead acetate, and other reagents, either changing the color of, or producing precipitates with, tannin and the coloring principle.

Vinum Portense.—*Port Wine*, E.; *Vin d'Oporto*, Fr.; *Portwein*, G.—This is the product of the grape cultivated in the district near the river Douro in Portugal, and is chiefly exported from Oporto. When recently made it is of a red color, which by age changes to a deep reddish-brown, while at the same time a considerable portion of altered astringent matter is deposited and the wine acquires its full flavor. Port wine is considered to be best when about eight or ten years old. As exported from Portugal, it is always mixed with a certain quantity of spirit, which is added for the purpose of better preservation; its alcoholic strength is thereby increased from 18 to 22 per cent. Ripeness and strength are said to be imparted to new wine by adding brandy toward the end of fermentation, and the product, particularly the cheaper varieties of port wine, is often artificially colored with preparations containing the juice of elderberries. Port wine has a pleasant vinous odor and an agreeable, warm, sweetish, and slightly astringent taste. In the place of true port wine a variety of French wine, known in commerce as Burgundy port wine, is much used in the United States; it resembles port wine in appearance and flavor, and contains about 14 or 16 per cent. of alcohol. California port wine is very similar, and is the product of grapevines originally obtained from the port-wine district of Portugal, and chiefly cultivated in Los Angeles County. Similar wines are also made in other parts of the United States.

Claret is the English name of dry red wines containing a moderate amount of alcohol, and was originally used for French red wines (*vin clairet*, clarified wine), but is now applied to many wines of American growth from California, as well as from the Mississippi Valley and eastward to the Atlantic coast. Some of the most esteemed red wines of France are produced in Gironde and exported from Bordeaux, and the red wines produced in other sections of France have, like the former, been known in Europe as Bordeaux wines. Much of the wine exported is more or less artificial, and the handsome red color is sometimes due to maqui-berries, the fruit of *Aristolelia* Maqui, L'Héritier (Fam. *Tiliaceæ*).

Constituents.—In addition to the constituents mentioned elsewhere (see Vinum Album), red wine contains tannin, partly derived from the casks, but mainly from the seeds and integuments of the grape, and giving with ferric salts green-brown or green-black precipitates. The red coloring matter, œnolin or œnolic acid, is a red-brown or purplish-red powder, which is nearly insoluble in water, in carbon disulphide, and in chloroform, but soluble in dilute acids and in alcohol; it is not unlikely that the coloring principles of different grapes vary, and are more or less modified by the constituents and treatment of wine.

Properties and Tests.—"Red wine occurs as a deep red liquid, having a pleasant odor, free from yeastiness, and a fruity, moderately astringent, pleasant, and slightly acidulous taste, without excessive sweetness or acridity. The specific gravity at 15.6°C. (60°F.) should be not less than 0.989 nor more than 1.010. If a portion of red wine be evaporated, the residue, when dried during twelve hours on a water-bath, should amount to not less than 1.6 per cent. nor more than 3.5 per cent.; this residue, ignited at a low temperature and burned gradually to whiteness, moistened with a small portion of ammonium carbonate test-solution, and again carefully ignited, should weigh not less than 0.22 Gm. nor more than 0.34 Gm. for each 100 Cc. of red wine tested. To neutralize 50 Cc. of red wine should require not less than 3 Cc. nor more than 5.2 Cc. of normal potassium hydroxide solution (limit of free acid), litmus test-solution being used as indicator. If 10 Cc. of red wine be diluted with an equal volume of water, and treated with 5 drops of ferric chloride test-solution, the liquid should acquire a brownish-green color (presence of tannic acid). With lead acetate test-solution, red wine forms a heavy precipitate which may vary in color from bluish-green to green. If 50 Cc. of red wine be treated with a slight excess of ammonia water, the liquid should acquire a green or brownish-green color; if it be then well shaken with 25 Cc. of ether, the greater portion of the ethereal layer removed, and evaporated in a porcelain dish with an excess of acetic acid and a few fibres of uncolored silk, the latter should not acquire a crimson or violet color (absence of red aniline colors). If 25 Cc. of red wine, heated to about 45°C. (113°F.), be well agitated with 25 Gm. of manganese dioxide, the liquid filtered off and acidulated with hydrochloric acid, it should not acquire a red color (absence of acid fuchsine). If 75 Cc. of red wine be acidified with 5 Cc. of diluted sulphuric acid (1 in 3) and thoroughly shaken in a separator with a mixture of equal parts of petroleum benzin and ether, and if the solvent after separation be transferred to a porcelain dish, allowed to evaporate spontaneously, and the residue dissolved in 3 Cc. of water, the solution should not have a sweet taste (absence of saccharin), nor should it give a violet color upon the addition of a diluted solution (1 in 200) of ferric chloride (absence of salicylic acid). Tested by the following method, red wine should be found to contain not less than 7 per cent., nor more than 12 per cent by weight (equivalent to 8.5 per cent. to 15 per cent. by volume), of absolute alcohol: Take the specific gravity (to four decimals) of a sufficient portion of the red wine accurately measured at the temperature of 15.6°C. (60°F.), evaporate the wine in a tared dish to one-third of its original weight, cool, and add water until the liquid measures its original volume at 15.6° C. (60°F.); then take the specific gravity (to four decimals) again. The difference between the two specific gravities deducted from 1.0000 corresponds to the specific gravity of an alcohol containing the same percentage of absolute alcohol, by weight or volume, as the wine under examination, the corresponding percentage being ascertained by referring to the alcohol tables."—U. S.

Action and Uses.—Red wine differs from white wine chiefly in containing a larger quantity of tannic acid than the latter. Because the tannic acid somewhat retards the absorption of the alcohol, red wine is preferred in convalescence where more of a tonic and less of an excitant effect is desired, and, on the other hand, is less serviceable as a remedy in low febrile states where a rapid, stimulating action is necessary. It is of particular benefit if slight laxity of the bowels occurs during convalescence.

VIOLA TRICOLOR.—Viola Tricolor.

Herba violæ tricoloris, P. G.; *Herba jaceæ.*—*Pansy, Heart'sease*, E.; *Pensée sauvage*, Fr. Cod.; *Stiefmütterchen, Freisamkraut, Dreifaltigkeitskraut*, G.; *Trinitaria*, Sp.

The dried wild-grown flowering herb of *Viola tricolor* L. (Fam. *Violaceæ*).

Origin.—The violets are mostly perennial, or rarely annual or biennial herbs, with alternate stipulate leaves, and with axillary flowers having five persistent auriculate sepals, five unequal petals, of which the lower one is saccate or spurred, five strongly connivent stamens, of which the two lower ones bear a spurred nectary upon the back, and one superior pistil with three placentæ, ripening into a 3-valved, many-seeded capsule; the globular or ovate seeds have a small caruncle and hard testa, and contain a straight embryo imbedded in fleshy albumen. The species official in the Pharmacopœia of 1880 is an annual or biennial indigenous to Europe and northern Asia, naturalized in the United States, and frequently cultivated in many varieties as an ornamental plant.

Description.—Pansy has a thin, spindle-shaped root and an erect or ascending angular and branching, nearly smooth stem, 10 to 20 Cm. (4–8 In.) high. The leaves vary between roundish cordate and oval, between crenate and nearly entire, are about 25 Mm. (1 In.) long, petiolate, and have prominent, leaf-like, lyrately pinnatifid stipules. The flowers are on long peduncles, and have the corolla partly yellowish, blue, and purple, or occasionally variegated and longer than the calyx (variety *vulgaris* Koch), or the corolla scarcely exceeds the calyx, and is yellowish or occasionally partly purplish (var. *arvensis*). The last form is the only one recognized by the French Codex; it is frequent in sandy fields of North America, and apparently indigenous. The dry herb is inodorous and has a bitterish, mucilaginous, and slightly acrid taste, the acridity residing mainly in the root.

Fig. 471.

Viola tricolor (¾ Nat.).

Constituents.—V. tricolor contains much gum, a little sugar resin, potassium nitrate, a small and variable amount of free salicylic acid and the yellow coloring matter *viola-quercitrin*, which yields 3 molecules of water, 1 of quercetrin, and a fluorescent body.

Action and Uses.—Viola tricolor was formerly employed as a "blood-purifier" and as a remedy in chronic affections of the lungs and intestines and in many cutaneous diseases, but is no longer used in scientific medicine. The alkaloid violine found in the roots of sweet violet (*V. odorata*) and in other members of the species resembles emetine in its effect, causing nausea, vomiting, and purging. A decoction of the root was used in the treatment of pulmonary diseases, and like ipecac in dysentery. A syrup of violets, made from the plants and flowers, is occasionally given as a mild laxative to children.

Other Species.—*Viola* L. contains more than 200 species, of which a score or more have been medicinally employed.

V. odorata L. (*Violette odorante*, Fr. Cod.; *Sweet* or *English violet*, E.; *Märzveilchen*, Ger.; *Violeta*, Sp.) is indigenous to Europe and northern Asia, is frequently cultivated, and grows to a certain extent spontaneously in various parts of North America. It has an oblique rhizome and produces long, filiform runners. The leaves are reniform or heart-shaped, obtuse, and crenate. The flowers are dark blue or sometimes whitish, bearded, and have a very agreeable odor. For pharmaceutical purposes the dark-blue flowers alone are collected, deprived of the calyx, and only the corolla is used, in the fresh state, for preparing Syrupus Violæ Odoratæ, *Fr. Cod.* Fresh violet-petals, 10 parts; boiling water, 20 parts; in 21 parts of the infusion dissolve 38 parts of sugar. V. odorata contains, especially in its rhizome, the alkaloid *violine*, which is obtained by removing from the alcoholic extract chlorophyll and fat by means of ether, boiling the residue with diluted sulphuric acid, adding to the filtrate lead oxide, evaporating, and exhausting the residue with strong alcohol. Violine is a yellowish, bitter, and fusible powder, which is more readily soluble in water than emetine, but less so in alcohol; is insoluble in ether, and appears to combine with acids to form not well-defined saline compounds. It merits further investigation. The blue coloring matter of violets turns green, and afterward yellow, with alkalies.

The flowers of this plant yield the highly fragrant body ionone.

V. pedata L., the Bird's-foot violet of the central and eastern United States, has been extensively used, and was at one time official.

Violaceæ, the *Violet Family.*—Many members of this family, especially in the genus *Hybanthus* Jacq. (more commonly known as *Ionidium* Vent.), possess ipecac-like properties similar to those of the violets, which are probably referable to the alkaloid violine. It chances also that the roots of a number of them resemble ipecac in appearance and have been used as substitutes for it. Among them, besides the "Ionidiums," are *Anchietea salutaris* St. Hil., the *Sipó* or *Sumá*, of Brazil, and several species of *Corynostylis*.

VITACEÆ.—The Vine or Grape Family.

This family comprises only about a dozen genera and 500 species of tendril-bearing shrubs. Its economic importance is great, through its production of grapes, raisins, wine, and brandy. Its medical importance relates chiefly to the last two, considered elsewhere. Unfermented grape-juice, containing very small proportions (1–1.5 per cent.) of alcohol, has of late years been extensively introduced. The following is also of some pharmaceutical importance:

Uvæ (Br.), *Uva passæ* (U. S., 1870), *Passulæ, Raisin* (Fr. Cod.).—*Raisins*, E.; *Rosinen, Zibelen*, G.; *Pasas*, Sp.

The dried ripe fruit of *Vitis vinifera* L. This species is indigenous to western Asia and probably to northern Africa, and has been cultivated in Europe from a very early period; it has been introduced into North America, chiefly on the Pacific coast, and into other temperate countries. A large number of varieties have been produced, differing in the shape, size, and color of their berries and in other characters. Some botanists refer the different varieties of grapevine to three or four species. The grapes commonly cultivated in the open air in central and eastern North America are cultivated varieties of native species, mostly of *V. Labrusca* L.

Until recently the world was chiefly dependent for its raisin supply upon southern Europe, especially Spain; but California has now come to occupy first place, at least so far as the United States is concerned. Between 1876 and 1900 the exportation of Malaga raisins to the United States decreased more than 95 per cent. When the grapes are ripe their stalks are cut half through, or a portion of the bark is removed, and the grapes are allowed to remain upon the vines for a few weeks, and then cut off, sometimes steeped for a short time in a weak lye to remove the waxy bloom, and then completely dried; or the ripe grapes are cut off, spread out upon a hard clay floor, and dried by exposure to the sun, which requires a week or two. In rainy weather artificial heat is used for drying them.

The ripe berry of the grapevine is one-celled from the obliteration of the cell-wall, and is globular or oblong in shape. After drying it is shrivelled and flattened, more or less orbicular, of a brownish color, and somewhat translucent. When long kept, raisins become more opaque, owing to the crystallization of the sugar and cream of tartar. Raisins are produced in southern Europe, and in commerce are distinguished generally by the ports of exportation.

Malaga raisins (*Uvæ malacensis*, Fr. Cod.; *Passulæ majores*) are the ordinary large raisins of southern Europe. Valencia raisins are removed from the bunch, while Muscatel raisins are sold upon it. Sultana raisins are smaller and are seedless. They formerly came from Asia Minor, but are now produced also in California. Corinthian raisins (English, Greek, or Zante currants; *Uvæ Corinthiacæ*, Fr. Cod.; *Passulæ minores*) are a small variety produced in Greece, sold after being removed from the bunch, and pressed together in hard, dark masses. The skin of ripe grapes contains tannin and coloring-matter. The chief constituents of the pulp are grape-sugar and acid potassium tartrate, besides gummy matter, calcium tartrate, and a small quantity of malic acid. The seeds contain about 5 per cent. of tannin, green resin, and over 10 per cent. of a bland oil.

The tender branchlets (*Pampini vitis*) with the leaves are sometimes employed for their agreeable acidulous flavor. The unripe berries (*Agresta*) contain a considerable amount of tartaric acid, and yield, when expressed, a very acerb juice (*Omphacium*), which after fermentation is *Suc de verjus* (Fr. Cod.).

Ampelopsis (*Virginia creeper, False Grape, American* or *Five-leaved ivy*, E.; *Vigne vierge*, Fr.; *Wilder Wein, Amerikanisher Epheu*, G.) is the bark and young branches of *Parthenocissus quinquefolia* (L.) Planch. (*Hedera q.*—L.; *Ampelopsis q.*—Mx.; *Cissus q.*—Pers.; *Vitis hederacea* Willd.), a very common and abundant woody climber, resembling a grapevine, of central and eastern North America, and extending into the West Indies. It climbs by means of sucking disks at the ends of its tendrils, and also by means of rhizoids. It is commonly cultivated for decorative purposes, the autumn foliage being very showy. It has digitate leaves composed of five oblong lanceolate, somewhat serrate leaflets, and cymose clusters of greenish flowers with five unconnected deciduous petals, and produces two-celled and two- or four-seeded acidulous blue-black berries of the size of a pea. The herbage is acidulous, from the presence of tartaric acid and its salts, and has been used as a refrigerant and diuretic. Other members of the family are used similarly.

VITELLUS OVI.—Yolk (Yelk) of Egg.

Jaune d'œuf, Fr.; *Eidotter, Eigelb*, G.; *Yema de huevo*, Sp.

The yolk of the egg of *Gallus Bankiva*, var. *domestica* Temminck (*Phasianus Gallus* L.—Order *Gallinæ*).

Origin.—The domestic fowl originated from the red jungle-fowl, *G. Bankiva*, which inhabits Japan and the adjacent islands, Northern India, Cochin China, and the Philippines. At the present time numerous varieties of it are found in all civilized countries. The egg (*Ovum*, U. S., 1870, *Ovum gallinaceum; Egg*, E.; *Œuf de poule*, Fr.; *Ei*, G.; *Huevo*, Sp.) consists of the shell and lining membrane 10.7 parts, albumen 60.4 parts, and yelk 28.9 parts (Prout, 1822).

Description and Composition.—The yolk of egg is a viscid yellow or reddish-yellow opaque liquid, which is without odor, has a bland taste, an alkaline reaction, and must be regarded as a dense emulsion consisting of oil suspended in water by

means of albumen. When triturated with water a whitish emulsion is obtained; the addition of alcohol causes it to coagulate, and when agitated with ether it separates a white mass and yields to ether an orange-yellow fat. Yolk is coagulated by heat. It contains 48 to 55 per cent. of water, 16 to 18 per cent. of vitellin (which is probably a proteid closely related to casein, and mixed with about one-fourth of albumen), 29 to 31 per cent. of fat (21.3 parts of which are olein and margarin, according to Gubley), 1.5 per cent. inorganic salts, coloring-matter, a small portion of sugar, and 0.42 of colesterin. Gubley has separated from the ethereal extract of yolk a substance which he named lecithin, and which on boiling with baryta yields neurine and stearic and phosphoglyceric acids. The fat obtained by expressing the coagulated yolk or by exhausting it with ether is occasionally used under the designation of oleum ovi (*oil of eggs*, E.; *huile d'œufs*, Fr.; *Eieröl*, G.).

Preservation.—Eggs may be preserved for a considerable length of time by covering the shell with a substance impervious to water, thus closing the pores so as to exclude the air. This may be done by wax, fat, paraffin, gum, or by similar substances. Packing them with the small end downward in dry salt, milk of lime, etc., has likewise been recommended.

Pharmaceutical Uses.—The yolk of egg is employed for emulsionizing fixed and volatile oils and camphors. It has no medicinal properties. The glycerite of yolk of egg (glyceritum vitelli ovi, U. S. P., 1890), also known as *glyconin*, is no longer official.

W.

WINTERA.—Winter's Bark.

Cortex winteranus.—Magellan Canella, Winter's cinnamon, E.; *Écorce de Winter*, Fr. Cod.; *Cannelle de Magellan*, Fr.; *Winter's Zimmt*, G.; *Corteza Winterana*, Sp., *Casca de Anta* or *de Tapir*, Port.

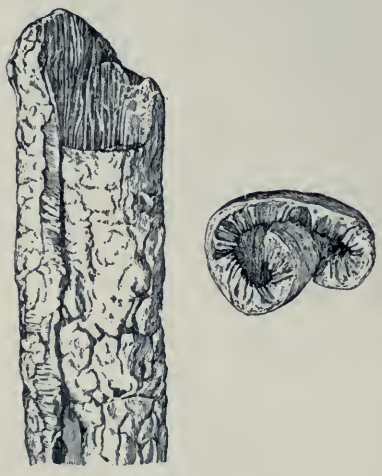
The dried bark of *Drimys Winteri* Forster (*Wintera aromatica* Murr.—Fam. *Magnoliaceæ*).

The prevailing view of systematic botanists is that all the forms of this plant growing from Mexico to Cape Horn should be included in the above species, which would thus reduce to synonyms the names *D. mexicana* Moc. et Sessé, *D. chilensis* DC., *D. granatensis*, L. f., and many others. From a study of the barks alone we should be led to reject this view, and we anticipate the separation of these forms into a group of species. Reports of analyses and other investigations should therefore be rigidly scrutinized as to the botanical source of the drug represented before being applied to the species here considered.

Description.—The bark occurs in very closely curled quills, occasionally as large as a man's wrist, and is distinguished by the great thickness of the bark, sometimes reaching 1 Cm. (nearly ½ In.). Externally it is dark gray, brown, or blackish, though the color is mostly concealed by a dense growth of whitish or gray lichens. The inner surface is of a deep rust brown and traversed by bast striæ in the form of strongly projecting blade-like ridges, separated by narrow, deep grooves, more prominent than in any other medicinal bark. The fracture is short and earthy, deep-red brown, coarsely mottled with whitish sclerenchyma, in tangentially elongated groups toward the cork, radially elongated toward the inner edge, and elsewhere scattered. Abundant resin-cells are visible, chiefly in the outer or inner zones. The odor is fragrant, the taste bitter and aromatic and bitingly pungent.

Origin.—These plants grow in the vicinity of the Cape as shrubs or dwarf trees, so gregariously that it is said to be less difficult for forest animals to travel over the surface of the mass than among the stems. Toward the north their growth becomes less dense, and their habitat is at a higher altitude, until, in the tropics, they are found only in the higher Andes. The typical plant appears to grow only in the extreme south.

FIG. 472.



Winter's bark (Nat.).

The properties of Winter's bark were made known by Captain Winter, of the British Navy, who, while cruising about the Cape, became storm-bound, ran out of supplies, and found his men dying of scurvy, of which they were cured by this bark, the properties of which he learned from the aborigines.

This most excellent aromatic bitter and anti-scorbutic has suffered greatly in reputation owing to the common substitution of a number of other barks for it, chiefly canella alba, cinnamodendron corticosum, and even cusparia. The bark of *D. granatensis*, which has come under our observation, has not the sharp bast ridges nor is it so pungent.

Constituents.—Winter's bark yields 0.65 per cent. of crude volatile oil, of which the essential part is *winterene* ($C_{15}H_{24}$), which distils between 255° and 260° C. (491°–500° F.), and has a specific gravity of about 0.935. Upon exposure it readily oxidizes and becomes yellow. The ethereal extract is a dark-brown viscid substance, containing a peculiar essence, fatty compounds, resins, and waxy matter, and showing no crystals on long stand-

ing. The alcoholic extract yields reddish uncrystallizable resins. The bark contains no citric acid, little or no tannin, and no ferric oxide, which have been reported in it. The bark of *D. granatensis* contains crystalline *drimin* ($C_{13}H_{14}O_4$). An attempt has been made to connect this variety with coto, but Hesse has shown that it contains no cotoin, and it certainly is not related. The leaves yield a wax alcohol, *drimol* ($C_{28}H_{58}O_2$). The Australian species, *D. axillaris* Forst and *D. lanceolata* have likewise pungently aromatic barks, and the fruit of the latter is used like pepper.

Action and Uses.—Winter's bark has aromatic properties resembling those of cascarilla. It is used as a tonic to the digestive organs, increasing the appetite and improving the digestion. The dose is from 20 to 30 grains (1.30–2 Gm.), given in powder or infusion.

X.

XANTHORRHŒA.—Acaroides Resin.

Resina lutea.—Acaroid, Yellow, Botany-Bay, Black-boy or Grass-tree Resin or *Gum.*

The solid balsam exuding from several species of *Xanthorrhœa*, Smith (Fam. *Liliaceæ*).

Origin and Description.—These plants are stout shrubs or small trees, with crooked terminal masses of grass-like leaves, native of dry regions in Australia. The resin is collected in the form of lumps or tears which concrete among the leaf-bases after spontaneous exudation. The head of leaves is chopped to pieces, and the resin threshed off. A large plant may yield more than 50 pounds. There are two varieties, known respectively as the red, chiefly from *X. arborea* R. Br., and the yellow, chiefly from *X. hastilis* R. Br. The latter, here described, is much the more fragrant and active, and is to be understood by the title, in the absence of other specification. The red is more commonly understood by the term "Black-boy Resin." A third variety, of orange-yellow color, from *X. tateana*, is of intermediate quality.

These resins occur, like dragon's-blood (see RESINA DRACONIS), in various forms, mostly in irregular, rough, brittle lumps, the color varying with the variety, as above defined. The odor is more or less benzoin-like.

Constituents.—The composition of the red and yellow varieties differs considerably. Tschirch and Hildebrand state that the yellow consists chiefly of resin which is mostly paracumaric ether of the resin alcohol xantoresinol ($C_{43}H_{46}O_{10}$). Xantoresinol yields much benzene and toluene. Vanillin, styracin, paracumaric, and cinnamic acids and the phenol-propyl ester of the latter occur. Of the red variety, the resin alcohol is called erythroresinotannol ($C_{40}H_{40}O_{10}$), and its paracumaric ether comprises most of the resin. There is much paracumaric but no cinnamic acid in this variety.

Action and Uses.—Acaroides resin has similar virtues to balsam of Tolu and storax. It is rarely used in medicine, but the red variety is employed to impart its color to varnishes.

XANTHOXYLUM, *U. S.*—Prickly Ash.

Toothache-tree, Suterberry-tree, Angelica-tree, or *Pellitory Bark*, E.; *Zahnwehrinde, Zahnwehholzrinde*, G.; *Clavalier, Frêne épineux*, Fr.

The dried bark of *Xanthoxylum Americanum* Miller (*X. fraxineum* Willd.), the *Northern Prickly Ash*, or of *Fagara Clava-Herculis* (L.) Small (*Xanthoxylum* C.—L.; *X. Carolinianum* Lam.), the *Southern Prickly Ash* (Fam. *Rutaceæ*).

Xanthoxylum is not official in any other pharmacopœia.

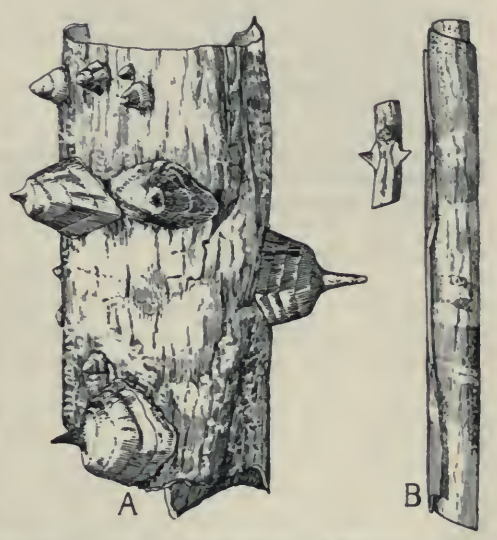
Origin.—These two genera of plants, so long confused with one another, are well distinguished by the absence of a corolla from the flowers of *Xanthoxylum*, while it is present in *Fagara.*

The Northern Prickly Ash occurs as a prickly shrub or very small tree throughout eastern and central North America, where the bark has been commonly used medicinally from aboriginal times. The Southern Prickly Ash varies from the size of a shrub to that of a tree, with a trunk diameter of 1 or 2 feet. It grows mostly in the Atlantic and Gulf States, from Virginia southward and westward. The trunk is prickly when young, afterward losing the prickles, but retaining the large corky warts upon which they were borne.

Description.—NORTHERN PRICKLY-ASH BARK occurs in small curved or quilled fragments, about 5 Cm. (2 In.) or less long, mostly about 1 Mm. ($\frac{1}{25}$ In.) thick, and occasionally mixed with pieces nearly 3 Mm. ($\frac{1}{8}$ In.) thick; corky layer very thin, of a brown-gray color, nearly smooth or faintly furrowed longitudinally, occasionally superficially fissured transversely, marked with some scattered warts, becoming transversely elongated, and usually bearing irregular whitish patches, numerous minute, black, and shining hemispherical dots, which are the perithecia of a lichen, probably a species of *Verrucaria*, and few brown,

glossy spines about 6 Mm. (¼ In.) long, straight, two-edged, and having a narrow linear base about 18 Mm. (¾ In.) long; outer bark, beneath the corky layer, of a green color, the inner bark whitish or yellowish; inner surface smooth, or finely striate if obtained from older branches; quite brittle, breaking with a short, non-fibrous fracture, and exhibiting upon transverse section a somewhat tangential arrangement of the tissue; inodorous, and of a slightly aromatic, bitterish, and strongly pungent taste.

Fig. 473.



Xanthoxylum bark: *A*, Southern; *B*, Northern (⅓ Nat.).

Southern Prickly-ash Bark occurs in very large quills or sheets, 1 to 2 Mm. ($\frac{1}{25}$–$\frac{1}{12}$ In.) thick, externally of a light purplish gray, with large silvery-gray patches, and marked by many large corky projections, often 2 Cm. (nearly 1 In.) high, many of them bearing stout brown spines; otherwise like the northern.

The cross-section exhibits narrow, nearly straight medullary rays, numerous scattered oil cells and calcium oxalate cells.

The bark of *Aralia spinosa* L. is known by the same common names as *xanthoxylum*, and is said to be occasionally substituted for it, doubtless by accident. It is transversely ridged, these ridges commonly bearing slender spines. Its taste is much less bitter and biting than that of xanthoxylum.

Constituents.—Although not absolutely identical, the two xanthoxylum barks are very similar in their composition. Both contain small amounts of volatile oil, fat, sugar, gum, acid resin, a bitter alkaloid believed to be berberine, and a colorless, tasteless, inert crystalline body, slightly different in the two barks, that of the northern having been named *Xanthoxylin*. Starch is wanting. Both barks yield a large amount of ash (12 per cent. or more), about a fifth of it water-soluble, the rest soluble in hydrochloric acid.

Xanthoxylum Fruits (*Prickly-ash Berries*).—The fruits of both the official species are used similarly to the barks. Each fruit consists of from 1 to 3, or occasionally 5 follicles, each about 5 to 8 Mm. in length, and about two-thirds as broad. In the northern species the follicles are separated, each on a short thecaphore; in the southern they are contiguous and sessile. The pericarp is dry, greenish gray-brown and roughish without, paler and smooth within, and contains one, or occasionally two, black seeds. Both pericarp and seeds are aromatic, pungent, and bitter, though the taste of the two is quite different. Their constituents have not been investigated, but they apparently agree in a general way with those of the bark.

Fig. 474.

Xanthoxylum, fruits and seeds: *A*, Southern; *B*, Northern.

Pharmaceutical Preparation.—Fluidextract of Xanthoxylum.—U. S. P.

Action and Uses.—The medicinal qualities of xanthoxylum are not well defined. It has mild diaphoretic properties, due, perhaps, to its feeble stimulant action upon the circulation and nervous system. Locally it is an irritant, and has been used as a sialagogue and as a topical application to influence deep-seated inflammation. Its employment as a remedy in chronic constitutional syphilis and rheumatism is based upon the resemblance of its virtues to those of mezereon and guaiac. It has also been used as an emmenagogue. The dose of prickly ash is from 20 to 60 grains (1.30–4 Gm.), administered in fluidextract or decoction. As a counterirritant, the decoction may be applied on compresses.

Other Species.—The genus *Fagara*, L., comprises, according to Engler, about 130 species, distributed through all warm and tropical regions; *Xanthoxylum*, L., about 9 species,

of temperate Asia and North America. Almost wherever these plants occur they have important uses, based on their aromatic, bitter, pungent, stimulating, and alterative properties. *F. Caribæa* (Lam.) Krug et Urb. (*X. Caribæum* Lam.), of the West Indies and northern North America, has been found to contain an alkaloid fatal to frogs and guinea-pigs. The fruits of *F. alata* Eckl. et Zeyh. (*X. alatum* Steud.) and of *Xanthoxylum piperitum* DC. are used in Japan as substitutes for pepper, and their barks for poisoning fishes.

F. Xanthoxyloides Lam. (*Xanthoxylum Senegalense* DC.) is the *Artar-root*, and contains two alkaloids, one named *artarine* ($C_{21}H_{23}NO_4$). In the Philippines, the bark of *F. oxyphylla* Edgew. is known as *Kayertana*. In Paraguay, that of *F. hyemalis* (St. Hil.) Engl. (*Xanthoxylum h.*—St. Hil.) is called *Tembotary Hu*, and in Brazil, that of *F. Tinguassiba* (St. Hil.) (*Xanthoxylum T.*—St. Hil.) is called *Casca de Tinguacibo*. *F. Retza* Roxb. (*Xanthoxylum R.*—DC.) is the *Rhetsa-Maram* of India, the root used as a purgative. *F. Budrunga* Roxb. is the East Indian *Budrang*. More than 30 species of these two genera are recorded as being medicinally employed.

Z.

ZEA, *U. S.*—Zea; Corn-silk.

Stigmata maydis.—Filament de mais, Fr.; *Maispistille*, G.; *Estyletes (Barbas) de Milho*, Port.

The styles and stigmas of *Zea Mays* L. (Fam. *Gramineæ*).

Origin.—The Indian Corn, or Maize plant, native of tropical America, and cultivated in all warm-temperate and tropical countries, is too well known to require description. The "corn silk" of the ear, the female inflorescence, constitutes the drug. There seems good reason to believe that its properties are more active in the fresh than in the dry condition, allowing for the loss of about 80 per cent. in weight.

It forms a loose, filamentous, tangled mass, green and usually partly reddish toward the summits of the filaments, drying of a dark reddish-brown. The styles are about 15 Cm. (6 In.) long, soft-silky, and very finely plumose, longitudinally delicately veined. It has a faint odor and a sweetish taste.

Constituents.—The only specific constituents of corn silk which are definitely known, and upon which its activity may depend, are its *resin* and *maizenic acid*. The latter is crystalline and soluble in both alcohol and water, as well as ether. Although the attempt to obtain volatile oil was unsuccessful, there is some volatile substance, since the drug has a distinct odor. Hillan, by treating it with an alkali and then distilling, obtained a very small amount of a substance which was basic and afforded alkaloidal reactions. Rademacher and Fischer obtained 5.25 per cent. of fixed oil, but it is probable that this percentage would vary considerably with the relative maturity. Small amounts of sugar, gum, and other ordinary plant principles were encountered. The ash amounts to about 12 per cent.

Action and Uses.—Corn-silk has diuretic and mild anodyne virtues. Its use is directed toward the alleviation of strangury, vesical pain, tenesmus, and other symptoms of the urinary tract, especially those due to phosphatic and uric-acid gravel. By French physicians it was highly esteemed as a diuretic in cardiac and renal dropsy. It appears to act more favorably in chronic than acute disorders of the urinary organs. The best preparation to administer is the infusion (2 ounces to the pint [60 Gm: 480 Cc.]), given in wine-glassful doses several times a day. The dose of the fluidextract is from ½ to 2 drachms (2–8 Cc.).

ZINCI ACETAS, *U. S.*, *Br.*—Zinc Acetate.

Zincum aceticum, P. G.; *Acétate de zinc*, Fr. Cod.; *Zinkacetat, Essigsaures Zinkoxyd, Essigsaures Zink*, G.; *Acetato de zinc*, Sp.

Formula, $Zn(C_2H_3O_2)_2 + 2H_2O$. Molecular weight, 217.82.

The Br. P. gives $Zn(C_2H_3O_2)_2 + 3H_2O$, but it has been proven that only 2 molecules of water are present.

It should contain in the uneffloresced condition not less than 99.5 per cent. of the pure salt, and should be kept in well-stoppered bottles.—U. S.

Preparation.—Digest for some time commercial zinc oxide (or carbonate), 2 parts, in acetic acid and distilled water, each 5 parts; then heat to the boiling-point, filter while hot, and set aside to crystallize. Drain the crystals in a funnel, and dry them upon bibulous paper. An additional quantity of crystals may be obtained by evaporating the mother-liquor to one-half, slightly acidulating with acetic acid and crystallizing.

On digesting zinc oxide or carbonate with acetic acid, the zinc is dissolved, in the latter case with the evolution of carbon dioxide; $ZnO + 2HC_2H_3O_2$ yields $Zn(C_2H_3O_2)_2 + H_2O$. An excess of the zinc compound is used to avoid loss of acetic acid, and is removed by filtration. The mother-liquor should be evaporated without boiling, so as to avoid loss of acetic acid and the formation of basic salt; acidulating the concentrated mother-liquid with a little acetic acid will restore the normal from the basic acetate, should the latter have been formed.

Properties.—Zinc acetate crystallizes in soft white pearly 6-sided tablets or scales, which on exposure to the air lose their transparency from the evaporation of some acid and water of crystallization, and have a slight acid reaction, a slight acetous odor, and a sharp metallic taste. The salt melts readily in its water of crystallization, and on continuing the heat parts with the same, the loss amounting to 22.8 per cent., which is gradually reabsorbed in a moist atmosphere. On dry distillation acetic acid, carbon dioxide, acetone, and empyreumatic products pass over, a white pearly sublimate is formed, and zinc oxide, mixed with a little charcoal, remains behind; when strongly heated in the air upon a porcelain plate, the salt is decomposed and burns with a greenish light and the production of a white smoke of zinc oxide. At 25° C. (77° F.) the salt dissolves in 2.5 parts of water and in 36 parts of alcohol; in 1.5 parts (2 parts, P. G.) of boiling water and in 0.6 part of boiling alcohol. Treated with sulphuric acid, it is decomposed with the evolution of acetic acid. The aqueous solution of the salt acquires a dark-red color with ferric salts, the color being discharged on the addition of hydrochloric acid, and yields white precipitates with potassium ferrocyanide, hydrogen sulphide, ammonium sulphide, ammonium carbonate, and potassium hydroxide, the precipitates with the last two reagents being completely soluble in an excess of the precipitant, and the colorless solution giving again a white precipitate with hydrogen sulphide.

Tests.—10 Cc. of the aqueous solution of the salt (1 in 20), acidified with 1 Cc. of hydrochloric acid, should not be colored or made turbid when mixed with an equal volume of hydrogen sulphide solution, and kept corked at 35° C. (95° F.) for at least half an hour (absence of arsenic, cadmium, lead, and copper). A 5 per cent. aqueous solution, acidified with diluted nitric acid, should remain clear on adding solution of barium chloride (absence of sulphate) or silver nitrate (absence of chloride). Five Cc. of the aqueous solution (1 in 10) should not respond to the modified Gutzeit's test for arsenic given under ARSENI TRIOXIDUM.—U. S.

Action and Uses.—Zinc acetate is used locally as an astringent and irritant. A solution containing 1 to 2 grains (0.06–0.12 Gm.) to 1 ounce (30 Cc.) of water is employed as a collyrium in conjunctivitis, and as an injection in gonorrhœal urethritis and vaginitis after the acute symptoms have subsided.

A mixture of 1 part of zinc acetate and 4 parts of aluminum naphtholsulphonate (alumnol) has been recommended as an antiseptic and placed on the market under the name *Zinol.*

ZINCI BROMIDUM, *U. S.*—Zinc Bromide.

Zincum bromatum.—*Bromure de zinc*, Fr.; *Zinkbromid*, G.; *Bromuro de zinc*, Sp.

Formula, $ZnBr_2$. Molecular weight, 223.62.

It should be kept in small glass-stoppered bottles, and should contain, when anhydrous, at least 97 per cent. of the pure salt.—U. S.

Preparation.—This salt is most conveniently prepared by digesting granulated zinc in hydrobromic acid, in which it dissolves with the evolution of hydrogen; the solution (filtered through asbestos or powdered glass) is carefully concentrated, acidulated with a little hydrobromic acid, and dried by the heat of a water-bath.

Properties.—Zinc bromide crystallizes with difficulty from its aqueous solution, and is therefore usually obtained in the form of a white granular powder. The salt is very deliquescent, has a slight acid reaction, is inodorous, and has a sweet and styptic metallic taste in diluted solution. It is freely soluble in water and in alcohol, and is also soluble in ether. Its aqueous solution yields with silver nitrate a white curdy precipitate, which is insoluble in dilute nitric acid and nearly insoluble in ammonia; it gives pure white precipitates of zinc compounds with the reagents mentioned under ZINC ACETATE. The salt melts on heating to 394° C. (741.2° F.), with partial decomposition, to a colorless or yellowish liquid which boils near 700° C. (1292° F.), and sublimes in white needles.

Tests.—If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, then chlorine water previously diluted with an equal volume of water, cautiously drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint (absence of iodide). On adding ammonium carbonate test-solution to the aqueous solution of the salt, a white precipitate is produced, which should completely redissolve in an

excess of the reagent. This test shows the absence of iron, aluminum, calcium, etc. The aqueous solution (1 in 20), to which sufficient hydrochloric acid has been added to insure a clear solution, should not be affected by hydrogen sulphide when treated as described under ZINCI ACETAS (absence of arsenic, cadmium, lead, and copper). Another portion of this solution should not be changed by addition of barium chloride test-solution (absence of sulphate). 5 Cc. of the aqueous solution (1 in 10) should not respond to the modified Gutzeit's test for arsenic given under ARSENI TRIOXIDUM. If 1 Gm. of the salt be dissolved in 50 Cc. of acetic acid, 2 Gm. of lead oxide (free from chloride) be added, and the mixture evaporated in a small beaker to at least 10 Cc., then the residue, diluted with 10 Cc. of distilled water and filtered, should give not more than a slight turbidity on the addition of 2 Cc. of nitric acid and a few drops of silver nitrate test-solution (limit of chloride). The object of this test is to get rid of the bromine by oxidation with the lead dioxide, thus, $PbO_2 + 2HBr + 2HC_2H_3O_2 = Pb(C_2H_3O_2)_2 + 2H_2O + 2Br$, lead acetate being formed. Chloride is not affected under the same conditions. If 0.3 Gm. of the anhydrous salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate test-solution be added, it should require not less than 26 Cc. nor more than 26.8 Cc. of tenth-normal silver nitrate solution to produce a permanent red color, corresponding to not less than 97 per cent. of the pure salt.—U. S. Each Cc. of the silver nitrate solution corresponds to 0.011181 Gm. of pure $ZnBr_2$, hence 0.3 Gm. of the pure salt would require theoretically 26.83 Cc. of the silver nitrate solution, and this is practically the same as the upper limit in the official titration, 26.8 Cc., which therefore represents almost 100 per cent. purity. The lower limit, 26 Cc. of silver solution, represents 0.2907 Gm. of $ZnBr_2$, or 96.9 per cent. If the upper limit of silver solution be overstepped appreciably, it would indicate an excess of chloride in the bromide which would also be apparent in the lead dioxide test for chloride.

Action and Uses.—Zinc bromide was proposed as a remedy in epilepsy, but is not used at present. If it be given in sufficient quantity to produce a bromide effect, enough of the zinc base would be ingested to cause symptoms of poisoning. The dose is stated to be from 1 to 2 grains (0.06–0.12 Gm.).

ZINCI CARBONAS PRÆCIPITATUS, *U. S.*—Precipitated Zinc Carbonate.

Zinci carbonas, Br.; *Zincum carbonicum.—Carbonate (sous-) de zinc hydraté, Hydrocarbonate de zinc*, Fr.; *Zinkcarbonat, Kohlensaures Zinkoxyd*, G.

Formula, $2ZnCO_3.3Zn(OH)_2$ (?). Molecular weight, 544.88 (?).

The British Pharmacopœia gives $ZnCO_3.2Zn(OH)_2.H_2O$, which is also found in nature.

Hydrated zinc carbonate, which, upon ignition, should yield not less than 72 per cent. of zinc oxide.—U. S.

Preparation.—Add a solution of 30 parts of crystallized zinc sulphate in 150 parts of water slowly from a dropping funnel to a filtered solution of 32 parts of crystallized sodium carbonate in 180 parts of water heated to boiling, and stir constantly. After boiling for 15 minutes, the flocculent precipitate becomes more granular and readily subsides. Decant the liquid and wash the precipitate with hot water, first by decantation and finally on the filter until the filtrate no longer gives a precipitate with barium chloride solution (sulphate). Press the filter and dry at 50° C. (122° F.).

The composition of the precipitated carbonate is variable, depending on the conditions of precipitation, as temperature, concentration, and drying of the salt. It contains 5 to 7 ZnO to $2CO_2$, but the proportion of water is variable. The formula given above is that formerly recognized by the U. S. P., while $3ZnCO_3.5Zn(OH)_2.H_2O$ is given by the French Codex. On mixing cold solutions of sodium carbonate and zinc sulphate, neutral zinc carbonate is precipitated; $Na_2CO_3 + ZnSO_4$ yields $Na_2SO_4 + ZnCO_3$. The gelatinous precipitate rapidly undergoes decomposition, carbon dioxide being evolved; and this renders another portion of the precipitate soluble. But if the mixture is boiled, the carbon dioxide is expelled from the liquid and the whole of the zinc is precipitated. Adding the solution of zinc sulphate to that of sodium carbonate while boiling hot keeps the precipitate free from sodium compound, and the sodium sulphate which is formed at the same time is readily removed by washing with water. Potassium carbonate is not so well adapted for this process as the sodium salt, because the resulting potassium

sulphate is less freely soluble in water; and ammonium carbonate is unsuitable, since a complete precipitation of the zinc cannot be affected.

Properties.—Zinc carbonate is a soft, impalpable, white, inodorous, and tasteless powder, permanent in the air, insoluble in water and other simple solvents, but dissolving readily in acetic and dilute mineral acids, with the evolution of carbon dioxide, and soluble also in aqueous solutions of ammonium salts. When heated in a crucible to redness it parts with its water and carbon dioxide and leaves oxide of zinc, which is yellow while hot, but white when cold.

Tests.—A small quantity of the salt, when moistened with a drop of cobaltous nitrate test-solution and heated before the blow-pipe, assumes a vivid green color (test for zinc). For tests of identity and purity, a solution is prepared by digesting 1.25 Gm. of the salt with 10 Cc. of diluted sulphuric acid and 10 Cc. of water, and, after action ceases, filtering off the excess of undissolved salt. In a portion of this solution a white gelatinous precipitate is produced by potassium ferrocyanide solution, and a pure white precipitate by ammonium sulphide solution. A coloration in these tests would indicate other metals. Another portion of the solution, acidulated with hydrochloric acid and mixed with an equal volume of hydrogen sulphide solution, should be unaffected after standing corked at 35° C. (95° F.) for at least ½ hour (absence of arsenic, cadmium, lead, and copper). Another portion of the solution should yield, with ammonium carbonate test-solution, a white precipitate which should dissolve completely in an excess of the reagent (absence of aluminum, calcium, etc.). If 1 Gm. of the salt be placed in a flask with 10 Cc. of boiling water and 2 drops of phenolphthalein test-solution be added, not more than one Cc. of tenth-normal hydrochloric acid solution should be required to discharge the red color (limit of alkali). One Gm. of the salt, after strong ignition in a porcelain crucible, should leave a residue of zinc oxide weighing not less than 0.72 Gm.—U. S.

Action and Uses.—Zinc carbonate is employed in ointment chiefly as a protective and mild astringent to abraded surfaces, superficial burns, and sluggish ulcers. As a dusting-powder, it allays the irritation of intertrigo.

ZINCI CHLORIDUM, *U. S., Br.*—Zinc Chloride.

Zincum chloratum, P. G.—*Chlorure de zinc*, Fr. Cod.; *Zinkchlorid, Chlorzink*, G.; *Cloruro de zinc*, Sp.

Formula, $ZnCl_2$. Molecular weight, 135.26.

It should contain, when anhydrous, not less than 99.5 per cent. of pure salt, and be kept in small glass-stoppered bottles.—U. S.

Preparation.—The directions for preparing Liquor Zinci Chloridi (p. 921) may be followed, except that the last filtrate is to be evaporated in a porcelain basin until a portion of the liquid, withdrawn on the end of a glass rod and cooled, forms an opaque white solid; the liquid is then poured into proper molds, and when the salt has solidified, but before it has cooled, it is placed in closely-stoppered bottles.

The reactions occurring in the preparation and purification of zinc chloride are explained on page 921. Since zinc chloride destroys vegetable fibre and transforms cellulose and starch into soluble modifications, its solution should not be filtered through paper, but through asbestos or powdered glass; otherwise the fused salt will be black. Toward the close of the evaporation of the solution the heat should be regulated so as not to decompose the salt, and in case the fused mass should become opaque from the separation of basic salt a little hydrochloric acid should be added. If the salt is desired for solution in water, the liquid is evaporated and continually stirred until a granular powder remains, a few drops of hydrochloric acid being added toward the close of the process.

Properties.—Zinc chloride is either in the form of a white crystalline powder or in opaque tablets or rods. It is inodorous, has a strongly caustic and metallic taste, is very deliquescent on exposure, has an acid reaction, and when heated to a little over 100° C. (115° C. = 239° F., U. S.) it melts to a colorless liquid which congeals to a white mass; at a higher heat it is partly volatilized, forming white fumes, and leaves a yellowish residue of zinc oxide, but when heated in a current of chlorine gas the salt sublimes in acicular crystals. Zinc chloride is soluble in 0.4 part of water at 25° C. (77° F.), but usually yields with water an opalescent solution from the presence of a little oxychloride, which

is readily dissolved by a few drops of hydrochloric acid; the solution dissolves starch, paper, and other organic compounds. Zinc chloride dissolves also freely in alcohol, and somewhat less freely in ether. In contact with sulphuric acid it is converted into zinc sulphate. Its solutions yield white precipitates with ammonium sulphide, ammonia, and with silver nitrate, the last two being readily soluble in an excess of ammonia. On mixing a concentrated solution of zinc chloride with zinc oxide a plastic mass of zinc oxychloride is obtained, which soon hardens, and is used as a cement in dentistry.

Zinc chloride forms well-crystallized double salts with ammonium chloride and derivatives of ammonia, as aniline, alkaloids, etc. The zinc ammonium chloride in solution is used to dissolve the coat of oxide on surfaces to be soldered, and is prepared by dissolving 10 parts of zinc in 50 parts of commercial hydrochloric acid, diluting with 10 parts of water, and adding 10 parts of ammonium chloride.

Tests.—The pharmacopœial requirements for the purity of zinc chloride are as follows: The aqueous solution (1 to 20) should be clear, or at most only very slightly opalescent, and, if it be mixed with an equal volume of alcohol, a single drop of hydrochloric acid should suffice to render 10 Cc. of the mixture perfectly clear (limit of oxychloride). It should not respond to tests for heavy metals, arsenic, calcium, etc., when applied as directed under ZINC BROMIDE, nor should the aqueous solution be rendered turbid by the addition of barium chloride test-solution (absence of sulphate). Dissolve 0.5 Gm. of the salt in 200 Cc. of boiling pure water, add about 5 drops of phenolphthalein test-solution, and then sufficient sodium carbonate test-solution, with constant stirring, to cause the solution to assume a permanent red color; transfer the resulting precipitate to a plain filter, wash it with boiling distilled water until all soluble matter has been removed, then dissolve it in a sufficient quantity of nitric acid, evaporate the solution to dryness, and ignite the salt until it ceases to lose weight; the residue should weigh not less than 0.297 Gm.—U. S. The steps involved are conversion of the chloride into carbonate, this into nitrate, and the latter into oxide, that is, $ZnCl_2$ becomes ZnO. 80.78 parts of ZnO correspond to 135.26 parts of $ZnCl_2$, hence 0.297 Gm. of ZnO represent 0.49729 Gm. of $ZnCl_2$ in the 0.5 Gm. taken for assay, or 99.46 per cent.

Pharmaceutical Uses.—CAUSTIQUE AU CHLORURE DE ZINC, Fr. Cod.—*Chloride-of-zinc pencils*, E.; *Pâte de Canquoin*, Fr.—Dissolve zinc chloride 32 Gm. in cold distilled water, 4 Gm.; add zinc oxide, 8 Gm., previously mixed with well-dried wheat flour, 24 Gm.; triturate so as to obtain a paste, and form this into cylinders or other shaped pieces, which are to be completely dried in an air-bath at a temperature gradually raised from 50° to 100° C. (122°–212° F.).

Action and Uses.—Applied locally zinc chloride is a powerful and painful caustic, ranking with potassium hydroxide and arsenic. Its action is confined to the area of application, no constitutional poisoning occurring as occasionally happens from arsenic through absorption of the drug. The severity of its effect is in proportion to the degree of its dilution with inert substances, to the quantity employed and the duration of its contact. The eschar formed by zinc chloride is white, thick and bloodless, sometimes called mummified, possesses little odor of sloughing tissue and falls away in from 8 to 12 days, leaving a healthy, granulating surface beneath. Zinc chloride may be used as a caustic for the destruction of cutaneous cancers, nævi and other tumors, and rodent ulcer when the timidity of the patient or his abhorrence for surgical procedures will not permit of excision of the growth. The pain attendant upon the employment of the caustic is no less, in fact is frequently more severe than that caused by the knife, and the healing process is prolonged. For cauterant purposes the zinc chloride is mixed with flour, gluten, zinc oxide, calcium sulphate or other inert substance and sufficient water or glycerin added to make a paste. The proportion of the chloride to the vehicle is 1 to 2, 3, 4 or five parts according to the degree of corrosion desired. The paste should be freshly prepared and a layer of it applied to the growth, covered with absorbent cotton and allowed to remain for from 3 to 6 hours. If the skin be intact over the tumor it should be removed by a blister before the caustic is applied. Of late years the employment of zinc chloride by cataphoresis for the cure of deep-seated tumors has been advocated by G. B. Massey and others, but this method has not met with the approval of the best minds in the profession. In the treatment of inoperable cancer of the vagina and uterine cervix, relief from hemorrhage and the sickening odor of the sloughing mass may be obtained by curetting away as much of the growth as can be safely done and applying a 50 per cent. solution of zinc chloride to the base. A solution containing 1

grain (0.06 Gm.) to an ounce (30 Cc.) of distilled water is used as an injection in the second stage of gonorrhœa, and a weaker solution, 1 grain to 4 ounces (0.06 Gm. –120.0 Cc.), as a collyrium in conjunctivitis, especially that variety known as "pink-eye." Zinc chloride is of no value as an internal remedy, although it has been recommended as an antispasmodic in epilepsy and chorea.

ZINCI IODIDUM, *U. S.*—Zinc Iodide.

Zincum iodatum.—Iodure de zinc, Fr.; *Zinkjodid*, G.; *Ioduro de zinc*, Sp.

Formula, ZnI_2. Molecular weight, 316.7.

It should be kept in small, glass-stoppered bottles, protected from light, and should contain, when anhydrous, not less than 98 per cent. of the pure salt.—U. S.

Preparation.—This salt may be prepared by dissolving zinc oxide or carbonate in hydriodic acid, or, according to Doepp (1839), by digesting in a flask 3 parts of granulated zinc, 10 parts of iodine, and 20 parts of water until the liquid has become colorless, when it is filtered through asbestos or powdered glass, and rapidly evaporated to dryness at a moderate heat. The yield is 12½ parts. The salt should be at once put into vials, which are to be kept carefully stoppered.

Properties.—Zinc iodide resembles zinc chloride and bromide, is a white graular, crystalline, inodorous powder, and has a sharp, saline, and metallic or in diluted solution a sweetish and styptic taste and an acid reaction. On exposure it is very deliquescent, and gradually becomes colored by, and acquires the odor of, free iodine. It is freely soluble in water and alcohol, and the solution on being largely diluted with water separates a gelatinous precipitate of zinc hydroxide (Rammelsberg). It readily forms basic compounds, an oxyiodide, soluble in warm and insoluble in cold water, being produced by the prolonged digestion of iodine and zinc with water. The iodide melts when carefully heated to 446° C. (834.8° F.) to a colorless liquid, and may be sublimed in quadrangular needles, but on being heated in the air is decomposed into iodine and zinc oxide. The aqueous solution gives white precipitates with ammonium sulphide, potassium ferrocyanide, ammonia, and potassium hydroxide, the last two being soluble in an excess of the precipitants, and it yields a scarlet-red precipitate with mercuric chloride, a bright-yellow one with lead acetate, and a pale-yellow one with silver nitrate, the latter being insoluble in ammonia and in nitric acid. The salt, warmed with strong sulphuric acid, liberates iodine and sulphur dioxide, zinc sulphate being formed at the same time.

Tests.—The absence of foreign metals is ascertained in precisely the same manner as in zinc chloride and bromide, and the absence of sulphate by the solution not producing a precipitate with barium chloride. If 1 Gm. of the salt be mixed with 5 Cc. of distilled water, and sufficient ammonia water be added to redissolve the precipitate formed, followed by a solution of 1.5 Gm. of silver nitrate in 10 Cc. of water, then, after shaking and filtering, the filtrate should not be rendered more than slightly turbid by the addition of an excess of nitric acid (limit of chloride). If 0.5 Gm. of the dry salt be dissolved in 20 Cc. of water, and if 35 Cc. of tenth-normal silver nitrate solution, 5 Cc. of nitric acid, and 3 Cc. of ferric ammonium sulphate test-solution be added, and the mixture well shaken, then the addition of not less than 3.4 Cc. nor more than 4 Cc. of tenth-normal potassium sulphocyanate solution should be required to give a permanent reddish-brown tint to the solution.—U. S. The volume of silver nitrate solution actually uniting with the zinc iodide is 31 (35 — 4) Cc. or 31.6 (35 — 3.4) Cc. As each Cc. of the silver nitrate solution corresponds to 0.015835 Gm. of pure ZnI_2, 0.5 Gm. of the pure salt would require theoretically 31.58 Cc. of the silver nitrate, this being practically equal to 31.6 Cc. allowed in the titration, which latter figure therefore represents 100 per cent. purity. If more than 31.6 Cc. of silver solution were required in the titration it would indicate an excess of chloride. The lower limit, 31 Cc., represents 0.4908 Gm. of ZnI_2, or 98.16 per cent.

Action and Uses.—Like other zinc salts, the iodide was recommended as a sedative in hysteria and chorea, and, like them, has fallen into disuse for this purpose. It was used as a mild caustic to enlarged tonsils, in solution of 10 to 30 grains (0.60–2 Gm.) to the ounce (30 Cc.). A solution containing 1 to 3 grains (0.06–0.20 Gm.) to the ounce (30 Cc.) of water is sometimes injected in subacute gonorrhœal urethritis and vaginitis. The dose of zinc iodide is from ½ to 2 grains (0.03–012 Gm.).

ZINCI OXIDUM, *U. S., Br.*—Zinc Oxide.

Zincum oxydatum, P. G.; *Flores zinci.—Oxyde de zinc*, Fr.; *Zinkoxyd*, G.; *Oxido de zinc*, Sp.

Formula, ZnO. Molecular weight, 80.78.

It should contain not less than 99.5 per cent. of pure zinc oxide.—U. S.

Preparation.—Place zinc carbonate in a loosely-covered Hessian crucible, and expose it to a dull-red heat until a portion, taken from the centre of the contents of the crucible and cooled, no longer effervesces when dropped into diluted sulphuric acid. Let the crucible cool, and transfer the product to stoppered bottles.

Nearly identical is the process of the French Codex for *oxyde de zinc par voie humide.* When heated, zinc carbonate parts with its water and carbon dioxide, leaving zinc oxide behind. A dull red heat is not necessary for this purpose. Mohr observes that a temperature of 280° C. (536° F.) is sufficient for obtaining the oxide, and, according to Hager, all carbon dioxide is expelled at 250° C. (482° F.). With quantities of from 6 to 12 ounces of zinc carbonate the operation is conveniently performed in a glass flask placed in a sand-bath and heated by means of gas or on a stove. The capacity of the flash should be about double the volume of the powdered carbonate. If the zinc carbonate is not previously powdered, a higher heat and a longer time are required for expelling all the carbon dioxide. If the carbon dioxide be driven off below a red heat, or if the heating to dull redness has not been prolonged unnecessarily, the cold zinc oxide has a white color, but after having been exposed to a full red heat it will retain after cooling a more or less decided yellow tint.

The French Codex recognizes also an *oxyde de zinc par voie sèche*, which is made by melting pure zinc in an inclined crucible in contact with air to a bright-red heat, when it takes fire and burns to oxide, which condenses in the upper part of the crucible or in suitable vessels suspended over it, and after cooling is passed through a fine sieve. The same product, though less pure, was recognized by the U. S. P., 1870, as ZINCI OXIDUM VENALE (zinc-white); *Zincum oxydatum crudum*, P. G.; *Flores zinci, Pompholix, Nihil album, Lana philosophica.* This was recommended by Courtois (1780) as a pigment in place of white lead, but began to be used as such about 1844, after Leclair had elaborated a process for making it at a sufficiently low rate. At present it is usually prepared directly from zinc ores by processes identical with or similar to those recommended by W. J. Taylor (1861) and G. Darlington (1862). A mixture of zinc ore and coal is packed in a suitable furnace upon a layer of coke, previously ignited, and heated by means of a blast, and the vapors of zinc oxide, which are at first more or less mixed with particles of charcoal, are conducted into a chamber, where they condense as a gray powder. As soon as the condensing product has a white color the vapors are passed into another chamber, where they condense as zinc-white The gray product is identical with the impure oxide of zinc, which was formerly used in medicine under the names of *tutia, cadmia fornacum*, or *tutty.*

Properties.—Zinc oxide is a soft, inodorous and tasteless, pale-yellowish, nearly white powder, which on being heated acquires a deep lemon-yellow color, and on cooling becomes again nearly white. When obtained by combustion of the metal, it is perfectly white. After having been heated to a bright redness it continues for some time to emit light in the dark. It dissolves in dilute acetic and other acids without effervescence, is completely insoluble in simple solvents and in saccharine liquids, and is without action on test-paper. It is soluble in caustic alkalies, but not in their carbonates; also in ammonia water and solution of ammonium carbonate. On exposure to the atmosphere it slowly absorbs water and gradually also carbon dioxide.

Tests.—A small portion of the oxide, moistened with a drop of cobaltous nitrate test-solution, and heated before the blow-pipe, assumes a vivid green color (test for zinc). For making tests of identity and purity, digest 1 Gm. of the oxide in a mixture of 10 Cc. of diluted sulphuric acid and 10 Cc. of water until saturated; then remove the undissolved part by filtration. Separate portions of this solution should behave in all respects like the corresponding solution of zinc carbonate toward potassium ferrocyanide, ammonium sulphide, hydrogen sulphide, and ammonium carbonate test-solutions when treated as directed under ZINCI CARBONAS PRÆCIPITATUS. Another portion of the solution should not be affected by silver nitrate test-solution (absence of chloride). 1 Gm. of the oxide should respond to the test for limit of alkali given under ZINC CARBON-

ATE. If zinc oxide be dissolved in diluted hydrochloric acid, the solution should not become more than slightly opalescent after the addition of barium chloride test-solution (absence of sulphate). If 1 Gm. of freshly ignited zinc oxide be digested with 30 Cc. of normal hydrochloric acid until dissolved, and 2 drops of methyl-orange test-solution be added, not more than 5.4 Cc. of normal potassium hydroxide solution should be required for neutralization (each Cc. of the normal acid consumed corresponding to about 4 per cent. of zinc oxide). The normal potassium hydroxide solution should be added slowly with constant stirring, waiting until the precipitated zinc hydroxide has redissolved before adding further portions of the reagent.—U. S. From the reaction $ZnO + 2HCl = ZnCl_2 + H_2O$, it follows that each Cc. of the normal hydrochloric acid corresponds to 0.04039 Gm. of ZnO, which is practically 4 per cent. of 1 Gm. 24.6 Cc. of the acid, the minimum allowed in the assay, represents 0.9936 Gm. of ZnO, or 99.36 per cent.

Action and Uses.—Zinc oxide was formerly given internally in many diseases for which it is now rarely employed. As an antispasmodic it was thought to do good in epilepsy, chorea, hysteria, and spasmodic asthma. For its astringent and acid qualities it was administered in diarrhœa in 2-grain (0.12 Gm.) doses with gratifying results. Like zinc sulphate it is sometimes of benefit in colliquative sweats, 1 grain (0.06 Gm.) being given every hour for 3 or 4 hours before bedtime. In fine powder or ointment it is an excellent application to allay the itching of intertrigo, the pain of superficial burns, and to promote the healing of excoriations, sores, ulcers, fissures of the nipples and anus, and many cutaneous eruptions. The dose of zinc oxide is from 1 to 4 grains (0.06–0.25 Gm.).

ZINCI PHENOLSULPHONAS, *U. S.*—Zinc Phenolsulphonate.

Zinci sulphocarbolas, Br., U. S., 1890; *Zincum sulphophenolicum.—Zinc paraphenolsulphonate, Zinc sulphocarbolate*, E.; *Sulphophénate de zinc*, Fr.; *Phenolsulfosaures Zink, Sulfokarbolsaures Zink*, G.

Formula, $(C_6H_4(OH)SO_3)_2Zn + 8H_2O$. Molecular weight, 551.56.

It should contain, in uneffloresced crystals, not less than 99.5 per cent. of the pure salt, and should be kept in small, well-stoppered bottles.—U. S.

Preparation.—The barium salt of paraphenolsulphonic acid is first prepared as described under SODIUM PHENOLSULPHONATE (which see). A definite quantity of the barium salt is then decomposed in solution by the exact equivalent of zinc sulphate, whereby insoluble barium sulphate is precipitated while zinc phenolsulphonate remains in solution, and is obtained by evaporation and crystallization.

Properties.—The salt occurs in colorless, transparent prisms or tabular crystals, odorless, and having an astringent, metallic taste, and an acid reaction to litmus-paper. It is efflorescent and, when exposed to light and air, may become slightly pink. It loses 6 molecules of water at 100° C. (212° F.) and the remainder at 125° C. (227° F.); at a higher temperature it chars and emits inflammable vapors having the odor of phenol, and finally leaves a residue amounting to about 14.6 per cent. of the original weight. It dissolves in 1.7 parts of water or alcohol at 25° C. (77° F.) and in 0.3 part of boiling water and in 0.56 part of boiling alcohol.

Tests.—A dilute solution of the salt (1 in 100) is colored violet by ferric chloride solution. The aqueous solution of the salt (1 in 20) should respond to the tests for zinc and for absence of heavy metals, iron, aluminum, calcium, arsenic by the modified Gutzeit's test, and sulphate, as described under ZINCI BROMIDUM. The solution (1 in 20) should not be affected by silver nitrate test-solution (absence of chloride).

Action and Uses.—Zinc phenolsulphonate may be used in solution (3 to 5 grains [0.20–0.30 Gm.] to an ounce [30 Cc.] of water) as an astringent application in subacute and chronic inflammations of mucous membranes as urethritis, vaginitis, tonsillitis, etc. It is rarely given internally as an intestinal antiseptic and astringent in diarrhœa and dysentery. Its dose is from 1 to 4 grains (0.06–0.25 Gm.).

ZINCI STEARAS, *U. S.*—Zinc Stearate.

Stéarate de zinc, Fr.; *Zinkstearat, Stearinsaures Zinkoxyd, Talgsaures Zinkoxyd*, G.

Preparation.—Zinc stearate is usually made by mutual decomposition between sodium stearate and zinc acetate, both salts being used in boiling hot solutions. 100

parts of zinc acetate will require 279 parts of sodium stearate, which latter may be procured in an impure form, as animal or curd soap, but is better prepared by adding stearic acid to a hot solution of monohydrated sodium carbonate. The precipitated zinc stearate, having been thoroughly washed with hot water, is dried and finally reduced to powder and passed through a hair-cloth sieve.

Properties.—Zinc stearate occurs as a fine white tasteless powder, having a very faint odor, resembling that of fat, and should have a neutral reaction to litmus-paper. It contains a small but varying proportion of zinc palmitate, and is insoluble in water, alcohol, or ether. When heated the salt fuses, and at a higher temperature is decomposed, giving off inflammable vapors and the odor of burning fat, and finally leaves about 15.5 per cent. of residue, chiefly of zinc oxide.—U. S.

Tests.—If 0.5 Gm. of the salt be heated with a mixture of 9.5 Cc. of distilled water and 0.5 Cc. of hydrochloric acid, stearic acid will be liberated and float as an oily layer on the surface of the liquid. If, after filtering this liquid through a wetted filter, all of the zinc be precipitated by ammonium sulphide test-solution, the filtrate should leave no fixed residue on evaporation (absence of alkalies, alkali earths, etc.). If 0.5 Gm. of the salt be heated with a mixture of 9.5 Cc. of distilled water and 0.5 Cc. of nitric acid and filtered, the filtrate should not become more than slightly turbid upon the addition of silver nitrate solution (absence of more than a trace of chlorides). If 1 Gm. of the salt be boiled with 50 Cc. of distilled water containing 2 Cc. of nitric acid, and filtered through a wetted paper, after thoroughly washing the precipitate (stearic acid) with boiling water, the filtrate and washings, when evaporated to dryness and ignited, should leave a residue weighing not less than 0.14 Gm. and not more than 0.16 Gm. (zinc oxide).—U. S.

Action and Uses.—Zinc stearate is one of the newer preparations recommended as a soothing, mildly antiseptic application for intertrigo, eczema, acne, and other cutaneous affections. It may be used either alone or combined with other powders or made into ointment.

ZINCI SULPHAS, *U. S., Br.*—Zinc Sulphate.

Zincum sulfuricum, P. G.; *Vitriolum album.*—*White vitriol*, E.; *Sulfate de zinc, Vitriol blanc. Couperose blanche*, Fr.; *Zinksulfat, Schwefelsaures Zinkoxyd, Weisser Vitriol, Galitzenstein*, G.; *Sulfato de zinc*, Sp.

Formula, $ZnSO_4 + 7H_2O$. Molecular weight, 285.41.

It should contain, in uneffloresced crystals, not less than 99.5 per cent. of the salt, and should be kept in well-stoppered bottles.—U. S.

Preparation.—Dilute 5 parts of sulphuric acid with 5 to 6 times its weight of water in a porcelain dish, and add 4 parts of granulated zinc. When effervescence has nearly ceased, aid the action by a gentle heat until no more hydrogen gas is given off. An excess of zinc should always be present to precipitate any lead, copper, cadmium, and arsenic. Filter into a bottle or flask, and add gradually, with agitation, a solution of chlorine, until a permanent odor of chlorine is perceptible. Then add some zinc carbonate and agitate until a brown precipitate (iron hydroxide) appears; let it settle, filter, slightly acidify with dilute sulphuric acid, evaporate the filtrate till a pellicle forms on the surface, and set aside to crystallize. Dry the crystals by exposure to the air on filtering-paper placed on porous tiles. More crystals may be obtained by again evaporating the mother-liquor.

Zinc dissolves in dilute sulphuric acid with the evolution of hydrogen, forming zinc sulphate: $Zn + H_2SO_4$ yields $ZnSO_4 + 2H$. Arsenic, copper, and lead, which are sometimes present in commercial zinc, are removed by the continued digestion with an excess of the metal, as ordered in the above process; but iron will dissolve, together with the zinc, to ferrous sulphate. This is converted into ferric salt by chlorine-water, and ferric hydroxide is now precipitated on agitating the liquid with precipitated zinc oxide or carbonate. The filtered liquid is free from the metals named, and on being sufficiently concentrated will yield crystals of pure zinc sulphate.

The same salt is economically prepared on the large scale from zinc-white, or by roasting the native zinc sulphide, ZnS, called *blende*, whereby this compound is oxidized to sulphate; this is extracted with hot water, and the clear solution, evaporated, yields crude white vitriol, which should be purified by redissolving it in water, boiling with

zinc, treating with chlorine and zinc carbonate, filtering, and evaporating to crystallization; magnesium and alkali sulphates are not removed by this treatment.

Properties.—Zinc sulphate crystallizes readily in large transparent rhombic prisms, which are isomorphous with those of magnesium sulphate. As seen in commerce, it is in small prisms or prismatic needles, obtained by disturbed crystallization from concentrated solutions. On exposure the crystals become slowly opaque from the loss of water of crystallization. When rapidly heated the salt melts. At a higher temperature it is partly decomposed, losing both water and sulphuric acid. At red heat it gives off SO_3, SO_2 and oxygen, while nearly pure ZnO remains. When very gradually heated to 50° C. (122° F.) it loses 5 molecules of its water (31.2 per cent.) without melting. At 100° C. (212° F.) a sixth molecule is lost, while the last is removed, with decomposition of the salt, at about 240° C. (464° F.). Zinc sulphate is inodorous, and has a strongly styptic and nauseous metallic taste and an acid reaction. It is completely soluble in 0.53 part of water at 25° C. (77° F.) and in 0.2 part of boiling water; soluble in 3 parts of glycerin (0.86 part, Fr. Cod.), but insoluble in alcohol. Supersaturated solutions are easily obtained, particularly in contact with air which has been previously filtered through cotton. The aqueous solution of zinc sulphate yields white precipitates with barium chloride ($BaSO_4$), with ammonium sulphide (ZnS), and with potassium ferrocyanide ($Zn_2Fe(CN)_6$).

The crude commercial zinc sulphate occurs in regular white masses, looking somewhat like lump sugar, and often exhibits here and there yellow stains, due to ferric oxide. It contains less water of crystallization, hence is less soluble than the pure salt.

Tests.—Commercial or crude zinc sulphate is not sufficiently pure for medicinal purposes; it contains iron, occasionally also copper, aluminum, and calcium sulphate, and sometimes cadmium. These salts and the alkali sulphates cannot be removed by recrystallization. Lead cannot be present in this salt if completely soluble in water, owing to the insolubility of its sulphate; yet the Pharmacopœia mentions it among the possible impurities. A small portion of the salt, moistened with a drop of cobaltous nitrate solution and heated before the blow-pipe, assumes a vivid green color (test for zinc). If 1 Gm. of zinc sulphate be shaken for some time with 10 Cc. of alcohol, the filtrate should not redden moistened blue litmus-paper, showing the absence of free acid. If a large proportion of chloride be present, the salt will be hygroscopic; a 5 per cent. solution of the salt, acidulated with nitric acid, should not be rendered more than slightly turbid by silver nitrate solution (limit of chloride). Other possible impurities are detected as follows: The aqueous solution (1 in 20), on being acidulated with hydrochloric acid and treated with hydrogen sulphide, as described under ZINCI BROMIDUM, should yield neither a yellow, brown, nor black coloration or precipitate (cadmium, arsenic, copper, and similar metals). In case iron be present the solution will afford with a little potassium ferrocyanide a more or less deep-blue precipitate. An excess of ammonium carbonate added to the aqueous solution should yield a clear and colorless liquid; in the presence of copper the color of the solution would be blue, and iron and aluminum would remain undissolved. The solution of the salt, after having been precipitated by ammonium sulphide, or the ammoniacal solution after treatment with hydrogen sulphide, yields a filtrate which on evaporation to dryness and ignition should leave no fixed residue (potassium, sodium, magnesium, and calcium). This test has been dropped from the U. S. P., 1900.

Composition.—Zinc sulphate has the formula given above, and contains 43.9 per cent. of water, 28.22 per cent. of zinc oxide, and 27.88 per cent. of SO_3. The sulphate may also be obtained with less water by crystallizing from its solution above 30° C. (86° F.). The crude commercial salt contains 3 molecules of water of crystallization.

Action and Uses.—Zinc sulphate is employed as an astringent and emetic. While it is used almost entirely as a local remedy, it is sometimes of value in serous diarrhœa in doses of 2 grains (0.12 Gm.), particularly if it be combined with opium. Its employment in chorea, epilepsy, asthma, whooping-cough, and other disorders in which it was formerly esteemed has been abandoned. Its emetic action is peripheral and usually prompt. It is useful to empty the stomach of indigestible and poisonous food narcotic poisons. The emetic dose is from 10 to 30 grains (0.60–2 Gm.), which may be repeated if the first dose does not produce vomiting. If vomiting does not occur after such quantities, symptoms of poisoning may arise and consist in abdominal colic, diarrhœa, and general prostration. Death is rare even from enormous doses. The usual

treatment for irritant poisons suffices, viz.: Demulcent drinks, opium for the pain, and hypodermic stimulation by strychnine and atropine to counteract the depression. In weak solution (1 to 3 grains to the ounce [0.06–0.20 Gm: 30 Cc.]) it is used as an astringent injection in gonorrhœa, as a collyrium in conjunctivitis after the subsidence of the acute symptoms, and as a stimulating application to indolent ulcers and moist skin diseases. Sir James Simpson recommended a paste made of desiccated zinc sulphate (1 ounce, 30 Gm.) and glycerin (1 drachm, 4 Cc.) as a mild caustic application to ulcers of the uterine cervix and soft tumors of the vagina and anus. The dose of zinc sulphate is from ½ to 2 grains (0.03–0.12 Gm.); as an emetic 10 to 30 grains (0.60–2 Gm.) should be given.

ZINCI VALERAS, *U. S.*—Zinc Valerate.

Zinci valerianas, Br., U. S., 1890; *Zincum valerianicum. Valérianate (Valérate) de zinc*, Fr. Cod.—*Zinc valerianate*, E.; *Zinkvalerianat, Baldriansaures Zinkoxyd*, G.; *Valerianato de zinc*, Sp.

It should contain not less than 99 per cent. of the pure salt, and should be kept in small well-stoppered bottles.—U. S.

Formula, $Zn(C_5H_9O_2)_2 + 2H_2O$, U. S.; $Zn(C_5H_9O_2)_2$, Br.; $Zn(C_5H_9O_2)_2 + 12H_2O$, Fr. Cod. Molecular weight, 301.28.

Preparation.—Take of sodium valerate 5 ounces avoirdupois; zinc sulphate, 5½ ounces avoirdupois; distilled water, a sufficient quantity. Dissolve the salts separately, each in 2½ pints of distilled water; raise both solutions to near the boiling-point, mix them, cool, and skim off the crystals which are produced. Evaporate the mother-liquor at a heat not exceeding 93.3 C. (200° F.) to 4 fluidounces, cool again, remove the crystals which have formed, and add them to those which have already been obtained. Drain the crystals on a paper filter, and wash them with a small quantity of cold distilled water till the washings give but a very feeble precipitate with barium chloride. Let them now be again drained and dried on filtering-paper at ordinary temperatures.

The above process was originally proposed by Trommsdorff. On mixing hot solutions of sodium valerate and zinc sulphate the salts are mutually decomposed, resulting in the formation of sodium sulphate, which remains dissolved, and zinc valerate, which crystallizes partly on cooling, the remainder being obtained on concentrating the liquid.

The salt of the French Codex is obtained by adding freshly prepared moist zinc carbonate to valeric acid, diluted with 30 parts of water, and when the acid is nearly saturated warming the mixture slightly, filtering, and carefully evaporating the liquid.

Properties.—Zinc valerate crystallizes in soft white pearly scales, which are not deliquescent, and have a slight odor of valeric acid, and a sweet styptic and metallic taste. It has an acid reaction on litmus-paper, melts at about 140°C. (284°F.), at a higher heat gives off white inflammable vapors, and finally burns with a bluish flame, leaving zinc oxide. The salt is soluble in about 50 parts of water and in about 35 parts of alcohol at 25°C (77°F.); somewhat more soluble in absolute alcohol (U. S.); the salt used in France, which contains $12H_2O$, dissolves in 50 parts of cold water (Fr. Cod.); on being boiled with water it loses water of crystallization. On heating the solution moderately it becomes turbid, and clear again on cooling; but after the saturated solution has been boiled it does not become entirely clear after cooling, in consequence of the production of a basic salt, which is less freely soluble in water. When kept over sulphuric acid the salt becomes anhydrous, and when exposed to the air it slowly loses valeric acid.

Tests.—If 0.5 Gm. of the salt be dissolved in 0.5 Cc. of hydrochloric acid diluted with 9 Cc. of water, the liberated valeric (iso-) acid will float as an oily layer on the water. After filtering through a wetted paper, the clear liquid should not be colored or rendered turbid by an equal volume of hydrogen sulphide solution, when kept corked at 35° C. (95° F.) for at least ½ hour (absence of arsenic, cadmium, lead, copper, etc.) The salt should dissolve without residue in ammonium carbonate test-solution (absence of iron, etc.). If 0.5 Gm. of the salt be dissolved in a mixture of 0.5 Cc. of nitric acid and 4.5 Cc. of distilled water, and the mixture filtered through a wetted filter, the filtrate should remain clear upon addition of either barium chloride solution (absence of sulphate) or silver nitrate solution (absence of chloride). If 0.5 Gm. of the salt be heated with 9.5 Cc. of distilled water and 0.5 Cc. of hydrochloric acid and fil-

tered, the filtrate should not respond to the modified Gutzeit's test for arsenic (given under ARSENI TRIOXIDUM.). 0.5 Gm. of the salt, triturated with 3 Cc. of water, 0.2 Cc. of ferric chloride test-solution, should give a filtrate free from red color (absence of acetate). Concentrated aqueous solutions of the salt and of copper acetate, when mixed, should remain perfectly clear (absence of butyrate). Zinc butyrate resembles the valerate closely; it is detected, according to the British Pharmacopœia, by distilling the suspected salt with dilute sulphuric acid and adding the distillate to a solution of copper acetate, when, if the valerate be pure, it does not immediately affect the transparency of the fluid, but forms after a little time oily drops, which gradually pass into a bluish-white crystalline deposit. This is the test suggested by Larocque and Hurant, who first directed attention (1846) to the similar physical properties of the two salts. The U. S. P. has adopted Hager's test.

Action and Uses.—Zinc valerate is devoid of pronounced medicinal virtues. As a mild antispasmodic it is sometimes of benefit in the treatment of neuralgic pains and headache occurring in hysterical females. It has been proposed as a remedy in diabetes insipidus, whooping-cough, infantile convulsions, and other disorders, which experience has shown are not affected by its use. The dose of zinc valerate is from 1 to 5 grains (0.06–0.30 Gm.) or more.

ZINCUM, *U. S.*—Zinc.

Speltrum.—Zinc, Fr.; *Zink*, G.

Symbol, Zn. Atomicity, bivalent. Atomic weight, 64.9.

It should contain not less than 99 per cent. of the pure metal.—U. S.

Zinc bears a very close resemblance to magnesium in its properties; in fact, the latter metal is a connecting link between the alkaline earth group of metals, calcium, strontium and barium, and the zinc, cadmium, and mercury group, all of which are bivalent, except mercury, which also is univalent in mercurous compounds.

The metal zinc has been known in the isolated state only since about the beginning of the eighteenth century, when Stahl showed it to be obtainable from calamine; some of its compounds, however, have been long known. Brass was used in ancient times, but no other metal besides copper was supposed to exist therein. The oxide was likewise known at an early date, and, like the ore from which it was obtained, was called *cadmia*. White vitriol appears to have been prepared by Valentinus in the fifteenth century, who was also acquainted with blende, in which Brandt (1735) showed the presence of zinc, and Glauber (1648) prepared "oleum lapidis calaminaris" and studied some of the properties of zinc chloride.

The metal is rather abundant, and exists most generally in combination either as carbonate, $ZnCO_3$, known also as *calamine*, *smithsonite*, *galmei*, and *zinc spar;* as silicate, Zn_2SiO_4, or *siliceous calamine;* as sulphide, ZnS, known as *sphalerite* or *zinc blende*. It also occurs as oxide, ZnO, or *zincite*, *red zinc ore*; *gahnite*, $Zn(AlO_2)_2$; and *franklinite*, $Zn(FeO_2)_2$ with $Fe(FeO_2)_2$. Zinc ores have been found in Pennsylvania and Missouri, in Great Britain, Belgium, and different parts of Germany, particularly in Silesia. They are frequently associated with lead and other metals.

CALAMINA PRÆPARATA (Lapis calaminaris præparata), which was dropped from the British Pharmacopœia, 1898, is native zinc carbonate, calcined in a covered earthen crucible at a moderate temperature, powdered, and freed from gritty particles by elutriation. It is a pale pinkish-brown powder, almost entirely soluble with effervescence in acids. The mineral varies in color from whitish to reddish or greenish, and is sometimes crystalline, or more frequently amorphous.

Preparation.—On smelting lead and other ores containing zinc an impure zinc oxide is condensed in the cooler portions of the furnace. By the long-continued roasting of blende or calamine, oxide is likewise obtained. This is mixed with powdered charcoal, and the mixture heated nearly to whiteness in shallow iron retorts, when the zinc distils, and is collected in suitable condensers. The impure metal is purified by a descending distillation in crucibles furnished with an open tube reaching to the upper half of the crucible and passing through its bottom.

Crude zinc is liable to contain iron, lead, copper, arsenic, antimony, cadmium, phosphorus, sulphur, and carbon. Such zinc is known as *spelter*. By repeated distillation it can be obtained pure. Distilled under reduced pressure, it forms lustrous crystals, which are extremely complicated in form. Most of the objectionable impurities of crude

zinc can be removed by oxidizing the melted zinc with potassium nitrate and subsequently fusing with zinc chloride. Iron, lead, and copper are not removed thus.

Zinc dust is the fine deposit formed when vapors of zinc first strike the cool walls of the condensing chambers. It always contains zinc oxide, and often cadmium. Good zinc dust should contain 80 to 90 per cent. of zinc. It can also be obtained by powdering zinc heated to about 300° C. (572° F.).

Granulated zinc is prepared by pouring molten zinc into cold water. It is a convenient form for use.

Properties and Tests.—Zinc is a bluish-white metal, having a lamellar or a granular structure. Its density varies between 6.9 and 7.2, rolled zinc being the heaviest. Ordinarily it is rather brittle, but between 120° and 150° C. (248° and 302° F.) it is ductile, and may be rolled into sheets and converted into wire. Heated to 205° C. (401° F.) it becomes so brittle that it may be reduced to powder. It melts at about 415° C. (779° F.) and at 940° C. (1724° F.) it boils and volatilizes, and in the presence of air burns with a bluish-green flame to oxide. Melted zinc on congealing expands in volume 0.2 per cent. (Nies and Winkelmann, 1882), and afterward contracts considerably. On bending, zinc emits a slight cracking noise, weaker than that of tin. It has a bright metallic lustre, but on exposure becomes superficially tarnished. It is not much acted on by cold concentrated sulphuric acid, but on heating unites with it, evolving sulphur dioxide. Diluted sulphuric and hydrochloric acids dissolve impure zinc readily, with the evolution of hydrogen, but pure zinc is scarcely acted on by these acids. The action can be increased, however, by adding a few drops of platinic chloride or of copper sulphate. Zinc is also soluble in caustic alkalies, with formation of hydrogen and soluble zincates, for example, $Zn(OK)_2$. Nitric acid dissolves zinc, but the nascent hydrogen reduces some of the acid to oxides, nitrogen, or ammonia, according to the conditions. Zinc precipitates most of the heavy metals from their solutions, for example, gold, platinum, silver, copper, lead, mercury, cadmium, arsenic, but iron, manganese, cobalt, and nickel are not precipitated. A good quality of zinc should contain no more than traces of iron, lead, and copper, but no arsenic, antimony, and phosphorus, for which the following tests may be applied: If 1 Gm. of zinc be dissolved in diluted hydrochloric acid, the hydrogen gas which is evolved should not have any disagreeable odor, nor should it color a strip of paper moistened with lead acetate test-solution (absence of sulphur) or with silver nitrate test-solution (absence of arsenic, antimony, phosphorus). The resulting solution should be clear and colorless, and should yield a white gelatinous precipitate with solution of potassium ferrocyanide, and a white precipitate with ammonium sulphide solution (colored precipitates would show the presence of foreign metals, as iron, copper, lead, etc.). If 1 Gm. of zinc be dissolved in a mixture of 10 Cc. each of nitrohydrochloric acid and water, the solution evaporated to dryness, the residue moistened with 2 Cc. of hydrochloric acid and again evaporated, and the final residue dissolved in 10 Cc. of water, this solution, acidulated with hydrochloric acid, should not be affected when mixed with an equal volume of hydrogen sulphide solution and kept corked at 35° C. (95° F.) for at least ½ hour (absence of arsenic, cadmium, lead and copper).—U. S.

Zinc is extensively used in the arts for roofing and other purposes; melted together with copper it forms brass (20 of zinc to 80 of copper). It is useful in protecting surfaces of iron and copper from oxidation; iron having its surface coated with zinc is known as galvanized iron. Zinc dust is used as a reducing agent in chemical analysis and in the arts, either in acids or alkalies, or in dry distillations. Zinc readily combines with mercury to form zinc amalgam, and plates thus coated are used in electric cells. Amalgamated zinc is acted upon much more slowly than zinc itself, and hence is protected against too rapid corrosion.

The *salts of zinc* are usually colorless, soluble in water, have an acid reaction, and a disagreeable metallic taste, and by prolonged heating are mostly converted into oxide. Their aqueous solutions, acidulated with hydrochloric acid, are not precipitated by hydrogen sulphide, but they yield with ammonia-water and potassium hydroxide solution white precipitates soluble in an excess of the reagents. White precipitates are also obtained with ammonium sulphide, alkali carbonates, and potassium ferrocyanide; potassium ferricyanide yields an orange-red precipitate.

UNOFFICIAL ZINC SALTS.

Zinci Cyanidum.—*Zinc cyanide*, E. ; *Cyanure de zinc*, Fr. Cod. ; *Zinkcyanid, Cyanzink*, G. $Zn(CN)_2$.—It is obtained by precipitating a solution of zinc acetate with hydrocyanic acid, whereby acetic acid is liberated, which retains a portion of the zinc cyanide in solution ; the liquid should therefore be kept nearly neutral by the occasional cautious addition of an alkali. Zinc cyanide is a white, inodorous, and tasteless powder, which is insoluble in water and alcohol, but dissolves in potassium hydroxide, ammonia-water, and in dilute acids. When long kept it undergoes decomposition and acquires a sweetish and metallic taste. The properties of zinc cyanade are similar to those of hydrocyanic acid and the other cyanides. It has been used in epilepsy, chorea, and other convulsive affections ; also in gastralgia and cardiac neuroses. The dose is from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.) every 2 or 3 hours.

Zinci et Potassii Cyanidum. $K_2Zn(CN)_4$.—On dissolving zinc cyanide in a solution of pure potassium cyanide a slightly alkaline liquid is obtained, which on evaporation yields colorless or white octahedrons of a sweet and metallic taste. Small quantities of acids precipitate from its solution zinc cyanide. This salt is used like zinc cyanidum, and in the same dose.

Zinci Ferrocyanidum.—*Zinc ferrocyanide*, E.; *Ferrocyanure de zinc*, Fr.; *Zinkferrocyanid*, G. $Zn_2Fe(CN)_6 + 3H_2O$.—It is prepared by precipitating a soluble zinc salt with potassium ferrocyanide, and forms a white tasteless powder, which is insoluble in water, alcohol, and dilute acids, and evolves hydrocyanic acid on being heated with dilute sulphuric acid. It is insoluble in ammonia-water, but soluble in warm sodium hydroxide solution. Zinc ferrocyanide resembles the cyanide in its action and uses. The dose is from 1 to 4 grains (0.06–0.25 Gm.).

Zinci Lactas.—*Zinc lactate*, E. ; *Lactate de zinc*, Fr. Cod. ; *Zinklaktat, Milchsaures Zink*, G. $Zn(C_3H_5O_3)_2 + 3H_2O$.—It may be prepared by dissolving zinc carbonate in dilute lactic acid with the aid of heat. It crystallizes in short quadrangular crystals which have an acid reaction and an acidulous metallic taste. The salt is not fusible, requires about 58 parts of cold and 6 parts of boiling water for solution, and is nearly insoluble in alcohol. It yields 27.1 per cent. of oxide of zinc. This salt was substituted for zinc oxide in epilepsy and other affections because it is less apt to irritate the stomach. The dose is from $\frac{1}{2}$ to 1 grain (0.03–0.06 Gm.) several times a day.

Zinci Permanganas.—*Zinc permanganate*, E.; *Zinkpermanganat, Uebermangansaures Zink*, G. $Zn(MnO_4)_2 + 6H_2O$.—Obtained by exact precipitation of barium permanganate with zinc sulphate, filtering and evaporating at a moderate temperature. It forms almost black crystals, deliquescent. The aqueous solution decomposes in air, but will keep when corked in dark bottles. It gives up oxygen more easily than does potassium permanganate, hence great care should be taken in bringing it together with combustible bodies. Zinc permanganate may be used like potassium permanganate, as an antiseptic and astringent application.

Zinci Phosphas.—*Zinc phosphate*, E.; *Zinkphosphat, Phosphorsaures Zink*, G. $Zn_3(PO_4)_2 + 4H_2O$.—Obtained by interaction between zinc sulphate and sodium phosphate in hot solution. A white powder, soluble in dilute acids and ammonia-water.

Zinci Phosphidum.—*Zinc phosphide, phosphuret of zinc*, E. ; *Phosphure de zinc*, Fr. Cod.; *Phosphorzink*, G. Zn_3P_2.—It may be prepared by Proust's process (1869) thus : Nitrogen gas is evolved by heating ammonium nitrite, and the gas is passed through a bottle in which hydrogen phosphide is prepared by introducing calcium phosphide through a wide tube into diluted hydrochloric acid contained in the bottle. The mixed gases are passed through a wash-bottle into a porcelain tube in which zinc is heated to redness, when the metal will combine with the phosphorus and liberated hydrogen will escape together with the nitrogen. If the apparatus is filled with nitrogen gas before the hydrogen phosphide is generated, there is no danger of an explosion. Zinc phosphide is stated to be permanent in the air, but the slight phosphorus odor emitted by it indicates its gradual oxidation ; it should, therefore, be preserved in well-stoppered vials. It forms a gray crystalline or friable mass, having upon the fractured surface a bright metallic lustre. When powdered and freed by sifting from metallic zinc which may be present, it resembles iron reduced by hydrogen, has a blackish-gray color and a slight taste of phosphorus, is readily soluble in dilute sulphuric or hydrochloric acid, with the copious evolution of hydrogen phosphide, and by concentrated nitric acid is converted into zinc phosphate. It melts at a higher temperature than zinc, and volatilizes unchanged, condensing in needles if the air be excluded ; but when heated in contact with air it is oxidized to zinc phosphate. Pure zinc phosphide consists of 24.12 per cent. of phosphorus and 75.88 per cent. of zinc. 1.171 Gm. of zinc phosphide in contact with official hydrochloric acid should evolve 200 Cc. of hydrogen phosphide, which should be completely absorbed by a concentrated solution of copper sulphate.—Fr. Cod. This test proves the absence of metallic zinc, which would evolve hydrogen ; hydrogen phosphide produces in the copper solution a black precipitate of copper phosphide. Zinc phosphide may be used in nervous exhaustion and other disorders in which free phosphorus is thought to do good.

Because of its stability it is more easily administered than phosphorus. Each grain represents about $\frac{1}{5}$ grain of phosphorus. The dose is from $\frac{1}{20}$ to $\frac{1}{10}$ grain (0.003–0.006 Gm.).

Zinci Salicylas.—*Zinc salicylate*, E.; *Zinksalicylat*, G. $Zn(C_6H_4.OH.COO)_2 + H_2O$.—It is obtained by boiling for a few minutes equivalent quantities of sodium salicylate and zinc sulphate in water, cooling, filtering the crystals, washing with a little cold water, and recrystallizing from hot water. The salt crystallizes in long satiny needles, has a sweet somewhat styptic and bitter taste, dissolves in about 20 parts of cold water, and is freely soluble in hot water, alcohol, ether, and methylic alcohol. Zinc salicylate is astringent and antiseptic. In solution of 1 to 5 grains to the ounce of distilled water it is used in the treatment of ophthalmia and gonorrhœa.

Zinci Sulphis.—*Zinc sulphite.* $ZnSO_3 + 2H_2O$.—Obtained by mixing aqueous solutions of zinc sulphate and sodium sulphite in the cold, filtering and washing the precipitate, and drying at low temperature. It is a white crystalline powder, soluble in about 600 parts of water. Boiling the salt with water converts it into a basic compound, with loss of sulphur dioxide.

Zinci Subgallas.—*Zinc subgallate.*—It is an odorless, greenish-gray, neutral powder, neither toxic nor irritating, and insoluble in ordinary solvents. It contains 56 per cent. of gallic acid and 44 per cent. of zinc oxide. Zinc subgallate is recommended internally, in the dose of $\frac{1}{2}$ to 5 grains (0.03–0.30 Gm.), as an astringent antiseptic in intestinal disorders arising from fermentation. Externally, it is applied in powder, or made into ointment for eczema, hemorrhoids, atorrhœa, etc.

ZINGIBER, *U. S.*, *Br.*—Ginger.

Rhizoma (Radix) zingiberis, P. A., P. G.—*Gingembre (gris et blanc*, Cod.), Fr.; *Ingwer*, G.; *Zenzero*, It.; *Zengibre*, Sp.; *Gengibre*, Port.

The dried rhizome of *Zingiber Zingiber* (L.) Rusby (*Amomum Z.*—L.; *Z. officinale* Roscoe.—Fam. *Zingiberaceæ*).

Ginger is official in all pharmacopœias, which are about equally divided as to requiring that it be peeled, not peeled, or partly peeled. The Italian specifies certain products (Chinese and Barbadoes) which it regards as most aromatic. Several specify that white-washed ("bleached") ginger shall not be used.

Origin and Preparation.—The Ginger plant is a rather tall, tufted, reed-like perennial, supposed to be native of tropical Asia, now known only in cultivation, and grown in nearly all tropical countries. It is propagated by planting small pieces of the rhizome. There is a blue- and a white-rhizomed form, the latter superior, but the former

Fig. 475.

Coated ginger.

Fig. 476.

Uncoated ginger.

productive upon soil that has become too poor to produce the white. Newly cleared forest soil produces the best ginger, as well as the largest crop, and the product of freshly rooted canes is superior to that from canes which have been growing for several years. Ginger grown and prepared with little care is called "Ratoon." The quality of ginger varies considerably in different countries and under different climates. The Fiji product is said to possess a peculiar lemon-like fragrance. The quality depends also largely upon the method of preparation. Strange to say, that upon which most time and care is bestowed, and which brings the highest price, namely, the Jamaica, is the least pungent of all, though presenting the most handsome appearance, and possessing

a flavor preferred by many persons. The rhizomes ("hands" or "races") are harvested after the herbage has completely withered, great care being taken not to bruise the surface, this resulting in discoloration. They are then allowed to dry sufficiently for the dirt to be easily and completely brushed or wiped off, or, if white ginger is to be produced, they are at once thoroughly washed. One of two courses may then be pursued in order that the ginger may dry promptly and safely. The first is the careful scraping off of the impervious integument, and subsequent gradual drying by repeated short exposures to the sun. This method results in the production of the handsome *white* or *peeled* ginger, which makes beautiful light-colored and fine-flavored preparations, but which has apparently lost much of its activity through this removal of the bark. The other method is the destruction of vitality by a 15-minutes' scalding in boiling water, the integument not being removed. The water is carefully watched, and is changed as soon as it becomes charged with the juices of the rhizome. By this method the starch is partly hydrated, afterward drying of a dark color, the product being known as *Black ginger*. Some unpeeled ginger is not dark colored or horny, and has apparently not been scalded. Unpeeled gingers are stronger and richer than those which are peeled.

Another form, called *Half-peeled*, is made by stripping off the bark upon the flat sides and then mildly scalding.

Description.—Peeled or White Ginger. From 5 to 10 Cm. (2–4 In.) long, flattened, 10 to 15 Mm. ($\frac{2}{5}$–$\frac{3}{5}$ In.) broad, and 4 to 8 Mm. ($\frac{1}{6}$ $\frac{1}{3}$ In.) thick, usually lobed or short-branched at one side, the branches thickened toward the end; deprived of the corky layer; pale buff-colored and strongly striate; breaking with a very starchy, rather fibrous fracture, and exhibiting numerous small scattered resin-cells and fibrovascular bundles enclosed within the endodermis; agreeably aromatic, pungent, and warming. The starch-grains are oval, oblong, or elliptical, flattened, have a small hilum, usually near the narrow end, and are finely annulate.

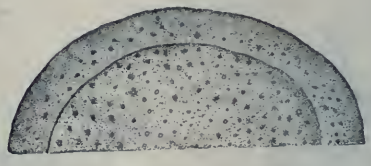
Coated or Black Ginger. In form and size similar to the last, but bearing the whole or a part of the integument, which is strongly, coarsely, and irregularly wrinkled, and varies from deep brown to blackish; fracture more or less dark and horny, otherwise the same as the peeled; granular starch more or less reduced in amount.

"Bleached" Ginger is commonly produced by dipping in chloride of lime, milk of lime, or gypsum, the object being sometimes to conceal defects in a badly cured product, sometimes to protect it against the attacks of insects, to which it is otherwise much subject. Some bleached ginger is produced by the action of sulphur fumes.

Fig. 477.

Ginger starch-granules.

Fig. 478.



Transverse section (× 3).

Varieties.—Aside from differences due to the methods of curing above described, various commercial varieties are recognized according to geographical sources. The Jamaican variety is characterized by our description. East Indian and African gingers are usually half-peeled and very closely resemble one another. They have a noticeably flat appearance, and the color ranges from dark gray to blackish. Chinese ginger is short, broad, and light colored. Cochin is similar to, but usually smaller than the Chinese, and the unpeeled parts are of a light reddish gray or brown.

Adulterants.—Adulteration of ginger in the entire condition is obviously not likely to occur frequently. The occurrence of a quantity of the limed rhizome mixed with nux vomica in the same condition, once reported, was doubtless accidental. Ground ginger is commonly adulterated, chiefly perhaps with that which has been exhausted of its active constituent. This is best detected by resulting variations in the active constituents and in the ash (see *Constituents*). Flour, curcuma, and various starchy matters are also used. To make up for the resulting loss of pungency, it is said that mustard and Cayenne pepper have been then incorporated. All these are readily enough detected by the aid of the microscope.

Constituents.—Besides a large amount of starch, a little gum and fat, and a variable amount of two resins, one acid, the other neutral, ginger contains two substances to which its activity is due. Volatile oil exists to the extent of from 1 to 3 per cent., and imparts the odor and flavor of the drug. Gingerol, which is not volatile or aromatic, but very pungent, exists in about half the amount of the oil. It is more viscid than the oil, colorless, neutral, and soluble in alcohol, ether, volatile oils, benzol, and carbon disulphide. Ether extracts from 4 to 8 per cent. of oleoresin. The ash amounts to about 4 or 5 per cent., and there are indications of the presence of an alkaloid.

The volatile oil of ginger consists of a thickish greenish-yellow liquid of 0.875 to 0.885 specific gravity, and requiring from 50 to 100 times its weight of 96 per cent. alcohol for solution. Its angle of rotation varies from —25° to —45°. It has the aromatic odor of ginger, but lacks the characteristic pungent taste of the drug. Thus far nothing is known regarding the source of the peculiar odor of oil of ginger. Among the constituents which have been isolated are dextro-camphene, having a specific rotation of + 63°13′ and occurring in the fraction distilling between 155° and 165° C. (311° and 329° F.), and phellandrene, distilling at about 170° C. (338° F.), and forming a nitrate melting at 102° C. (215.6° F.). The bulk of the oil boils between 256° and 266° C. (492.8° and 510.8° F.), and consists chiefly of a sesquiterpene, $C_{15}H_{24}$, which does not form a solid compound with hydrochloric acid.

Pharmaceutical Preparations.—Fluidextract of Ginger, Oleoresin of Ginger, Syrup of Ginger, Tincture of Ginger, U. S. P.

Action and Uses.—Ginger is a warm, stimulating carminative when taken internally, and when applied to the skin is an efficient rubefacient and counterirritant. When chewed it stimulates the secretion of saliva and if snuffed into the nostrils in powder it occasions sneezing. It relieves abdominal cramp due to flatus and is an useful addition to diarrhœa mixtures, bitter tonics, and to preparations given to correct indigestion. As a rubefacient it is made into a cataplasm either alone or in combination with other spices for the relief of colic, headache, myalgia, neuralgia, etc. The preparation most frequently employed for internal use is the tincture in the dose of ½ to 2 drachms (2–8 Cc.). The dose of powdered ginger is from 10 to 30 grains (0.60–2 Gm.). In domestic practice an infusion, "ginger tea" (½ ounce to 1 pint [16 Gm to 480 Cc.] of boiling water), is largely employed.

Other and Related Products.—*Preserved Ginger* consists of the rhizomes gathered and preserved long before maturity and while still tender. They are preserved in sugar by complicated processes, differing with the locality and the maker. The most highly esteemed is the Chinese, which seems not to be ginger at all, but the related rhizome of a species of Alpinia.

The genus *Zingiber* Adans. contains about 20 species, all Asiatic, and the rhizomes of about half of them are used as aromatics. The *Zerumbet Root* of Java is yielded by the *Z. Zerumbet* (L.) Roscoe (*Amomum Z.* L.), and that of *Z. amaricans* Noronha is also sold under this name. Zerumbet is tuberous, somewhat flattened, spongy, internally yellowish, with pale-brown fibrovascular bundles, and has an agreeable odor and a ginger-like, somewhat bitter taste.

The Cassumuniar-root of India is yielded by *Z. Cassumuniar* Roxb. It is about 5 Cm. (2 In.) in diameter, jointed, compressed, with numerous white fleshy radicles and some white tubers; it is externally scaly and light brown, internally yellow and rather woody, and has a camphoraceous odor and a hot, aromatic taste.

Zingiberaceæ.—The Ginger Family comprises 24 genera and about 300 species of plants, wholly tropical, chiefly in the Old World, and distinguished for their aromatic properties, like Ginger, Cardamon, Galanga, Curcuma, and Zedoary, all of which are elsewhere described. Many species of the genus *Costus* are used for their aromatic properties. The viscid, acrid, expressed juice of *C. discolar* Rosc. is used in Brazil as a local application in gonorrhœa, while the decoction of the plant is used internally as a genito-urinary stimulant. The Venezuelan Indians chew the stem of *C. spiralis* Rosc. as a stimulant on fatiguing journeys, especially when water is scarce.

Very closely related to this family are the *Marantaceæ*, yielding arrow-root, considered under *Amylum*, and the *Musaceæ* or *Banana-family*. The latter is of more interest for its nutrient than for its medicinal properties. Banana-root has some employment as an anthelmintic, and has been reported useful in reducing bronchocele. The young shoots of several species are cooked and eaten. The fibre of the mature leaves is used in cordage. The great importance of the family resides in the use of the unripe fruits as food, and to a much less extent in that of the ripe fruit. It has been estimated that, weight for weight, bananas on

plantations are more than 44 times as productive as potatoes. Allowing for the most extreme exaggeration in this statement, it yet fully explains why this is the favorite food-plant of the indolent natives of the tropics. The ordinary banana, red and yellow, is *Musa sapientum* L. Whether the plantain, which is larger, coarser, better adapted for use as a food, but less as a ripe fruit, is but a cultivation-form or a distinct species may always remain in dispute. The same is true of the most delicately flavored and delicious variety, the Green banana, of a pale-green color when ripe, and which has been referred to *M. Paradisiaca* L. Unripe bananas are eaten roasted, baked, boiled, fried, as an ingredient of soups and stews, and, in general, as potatoes are used, possessing thus, like the potato, only a slight or negative flavor and no sweetness. They are also dried and ground into flour as meal, to which Coppoch assigns the following composition: water 10.62, albuminoids 3.55, fat 1.15, carbohydrates 81.67 (more than two-thirds starch), fibre 1.15, phosphates 0.26, other salts 1.60. The sugar is chiefly cane-sugar.

ZYGOPHYLLACEÆ.—(The Guaiac Family.)

A peculiar little family of 21 genera and about 6 times as many species, mostly of tropical or warm countries. Medicinally, the family most resembles the RUTACEÆ, and is well represented by guaiac. Its active constituents are chiefly oleoresins.

Harmal or *Ispand* is the seeds of *Peganum Harmala* L. of India, used in that country as a genito-urinary stimulant and anthelmintic. They are also counted mildly narcotic, with properties somewhat resembling those of CANNABIS. The root is applied to the scalp as a parasiticide. The seeds are described by Hooker as about ⅛ inch long, irregularly angular, dull grayish brown, of a heavy narcotic odor when crushed, and a bitter taste. They yield a reddish oil and a carmine-colored soft resin, both nauseous, a little more than 1 per cent. of the alkaloid *harmine* ($C_{13}H_{12}N_2O$), and nearly 3 per cent. of *harmaline* ($C_{13}H_{14}N_2O$), besides yellow fluorescent coloring-matter. The latter is regarded as identical with *harmatol*, obtained from harmaline by treating it under pressure with hydrochloric acid. The crystalline yellow harmalinates are also highly fluorescent in solution. Harmine can be obtained by oxidation of harmaline, and is, on further oxidation by chromic acid, converted into harminic acid, in silky tufts. *P. erithmifolium* Retz. is used in Europe, and *P. Mexicanum* Gray in Mexico.

Hengam or *Gari*, sometimes known as Bombay colocynth or Egyptian myrobalans, is the unripe fruit of *Balanites Egyptiaca* Del., assuming this to be identical with *B. Roxburghii* Pl. of India. All parts of the plant appear purgative and anthelmintic, and are variously employed in different parts. Saponin appears to be the active constituent of the bark, and probably also of the pulp of the unripe fruit. The dried fruit, in general appearance, somewhat resembles a large walnut, being broadly oval, about 7 Cm. (2 In.) long, smoothish, 10-grooved, and brownish. The pulp is about ¼ inch thick, and contains a large pentagonal stone, containing a single oily exalbuminous seed. The seed yields 50 per cent. of a slow-drying yellowish oil, resembling peanut oil, which is devoid of special properties.

Various species of *Zygophyllum* are employed as anthelmintics, and *Z. spinosum* L. of the Cape is said to be poisonous. *Tribulus terrestris* L., the East Indian *Chota*, introduced into many warm regions, contains considerable tannin, and is used variously as an astringent and tonic. *Covillea tridentata* (DC.) Vail (*Larrea t.*—DC.; *L. Mexicana* Moric) and other species of *Covillea* of Mexico and the southwestern United States are known as *Creosote bush*, because of the peculiar odor exhaled. The herbage is very glutinous from the exuded oleoresin, and is strongly suggestive of medicinal properties. These it doubtless possesses, but they have never been investigated. Sonora gum or Arizona shellac is produced upon this plant.

APPENDIX.

LIST OF REAGENTS AND TESTS

Employed in Chemical Testing, according to the United States Pharmacopœia.

THE insertion of all the official methods as well as solutions, both for qualitative and quantitative tests, is rendered imperative by the frequent reference to the pharmacopœial requirements in the preceding pages.

Strictly pure (distilled) water is to be used in the preparation of the test-solutions as well as in the application of tests; the former should be perfectly transparent and kept in well-stoppered bottles, protected against extremes of temperature.

1. General Reagents and Test-solutions.

Absolute Alcohol.—Use the official absolute alcohol (see p. 124).

Acetic Acid.—Use the official acetic acid (see p. 30).

Albumen Test-solution.—Carefully separate the white of a hen's egg from the yolk, shake it thoroughly with 100 Cc. of water, and filter. This solution should be freshly made when required.

Alcohol.—Ethyl Alcohol, C_2H_5OH.—Use the official alcohol (*Alcohol*, U. S. P.). Alcohol of lower strength is prepared as follows:

Alcohol, 90 per cent.—Mix 51 Cc. of alcohol with 3 Cc. of distilled water. The specific gravity of the mixture should be 0.826 at 25° C. (77° F.), corresponding to 90 per cent., by volume, of absolute alcohol.

Alcohol, 80 per cent.—Mix 45.5 Cc. of alcohol with 9.5 Cc. of distilled water. The specific gravity of the mixture should be 0.856 at 25° C. (77° F.), corresponding to 80 per cent., by volume, of absolute alcohol.

Alcohol, 70 per cent.—Mix 38.6 Cc. of alcohol with 15 Cc. of distilled water. The specific gravity of the mixture should be 0.882 at 25° C. (77° F.), corresponding to 70 per cent., by volume, of absolute alcohol.

Aluminum.—Metallic aluminum in the form of foil, wire, or ribbon. It should be tested for arsenic by Fleitmann's method, when no color should be imparted to the silver nitrate within two hours.

Ammonia-water.—Use the official ammonia-water (see page 210).

Ammonium Carbonate Test-solution.—Dissolve 20 Gm. of ammonium carbonate, $NH_4HCO_3.NH_4NH_2CO_2$, in a mixture of 20 Cc. of ammonia-water and 70 Cc. of water, and add sufficient water to measure 100 Cc.

Ammonium Chloride Test-solution.—Dissolve 10 Gm. of pure ammonium chloride in enough water to make 100 Cc.

Ammonium Molybdate Test-solution.—Dissolve 15 Gm. of finely powdered ammonium molybdate, $(NH_4)_6Mo_7O_{24} + 4H_2O$, in 100 Cc. of distilled water, adding sufficient ammonia-water, if necessary, to effect solution. Then gradually pour the liquid into 100 Cc. of nitric acid (specific gravity 1.403 at 25° C. [77° F.]). The resulting solution, after being subjected to gentle heat for about two hours, should be decanted from any yellow sediment which may be deposited.

Alternative Method.

Solution No. 1.

Molybdic acid, H_2MoO_4	10 Gm.
Ammonia-water (10 per cent.)	42 Cc.

Solution No 2.

Nitric acid (specific gravity 1.403) } Water }	*āā* 63 Cc.

Pour Solution No. 1 into Solution No. 2 gradually, shaking repeatedly. After being subjected to a gentle heat for about two hours, the solution should be decanted from any yellow sediment which may be deposited.

Preserve the test-solution in the dark, and, if a sediment should form in it after some days, carefully decant the clear solution from it.

Ammonium Oxalate Test-solution.—Dissolve 4 Gm. of pure, crystallized ammonium oxalate in enough water to make 100 Cc. Or dissolve 4 Gm. of pure oxalic acid in 100 Cc. of water, add 15 Cc. of ammonia-water, boil to expel excess of ammonia, and bring the volume to 113 Cc.

On evaporating a portion of the test-solution and igniting the residue, it should be completely volatilized (absence of fixed impurities). The test-solution should not be rendered turbid by hydrogen sulphide nor by ammonium sulphide (absence of metals). The precipitate produced in it by silver nitrate or by barium chloride should dissolve without residue upon addition of nitric acid (absence of chloride and sulphate, respectively).

Ammonium Sulphate, $(NH_4)_2SO_4$.—This salt should respond to the following tests of purity: Three grammes should leave no appreciable residue upon ignition (absence of fixed impurities). The aqueous solution of the salt (1 in 10) should not respond to the time-limit test for heavy metals (see below).

Another portion of this solution should not become turbid upon the addition of nitric acid and silver nitrate test-solution (absence of chlorides). Another portion of this solution should not be colored red upon the addition of 2 drops of hydrochloric acid and 1 drop of ferric chloride test-solution (absence of sulphocyanate). This salt may be prepared by neutralizing pure sulphuric acid, which has been diluted with an equal volume of water, with ammonia-water, evaporating and crystallizing. During the evaporation the solution should be tested from time to time with litmus-paper, adding more ammonia, if necessary, to keep the liquid alkaline.

Ammonium Sulphide Test-solution.—Saturate 3 parts of pure ammonia-water with pure, washed hydrogen sulphide, and add to the solution (which now contains ammonium sulphhydrate) 2 parts of ammonia-water, which converts the greater portion of the ammonium sulphhydrate into ammonium sulphide. The solution should be perfectly clear and colorless, and, on being evaporated, leave no residue. It should not be rendered turbid either by magnesium sulphate (absence of free ammonia) or by calcium chloride (absence of ammonium carbonate). It should be protected against air and light by being kept in small, dark amber-colored bottles in a dark place. As soon as a notable deposit of sulphur has made its appearance in the solution, it should be rejected.

Ammonium polysulphide test-solution is occasionally required. This is a yellow liquid, prepared by dissolving a small quantity of pure sulphur in the preceding colorless ammonium sulphide test-solution.

Amyl Alcohol, $C_5H_{11}OH$.—A colorless, oily liquid having a penetrating characteristic odor, boiling at 131° C. (267.8° F.); soluble in 40 parts of water at 25° C. (77° F.); miscible with alcohol, ether, chloroform, carbon disulphide, petroleum benzin, benzene, and fixed and volatile oils.

Aniline (Phenylamine), $C_6H_5NH_2$.—When freshly distilled, aniline is a colorless, strongly refractive, oily liquid, having a peculiar aromatic odor, and a pungent, burning taste. Upon exposure to the light and air it rapidly assumes a reddish-brown color. Specific gravity 1.0214 at 25° C. (77° F.). Aniline should distil over completely between 183° and 184° C. (361.4°–363.2° F.). It is soluble in alcohol, ether, and the fixed and volatile oils. With acids, it forms soluble crystalline salts. When added to a solution of calcium or sodium hydrochlorite a blue or purple color is produced.

Arsenic Test, Bettendorf's.—(See p. 249.)

Arsenic Test, Fleitmann's.—Into a test-tube of at least 15 Cm. in length and 15 to 18 Mm. in diameter place a single, solid piece of zinc (see below), weighing about 1 to 1.25 Gm., and add about 5 Cc. of potassium hydroxide test-solution, both ingredients having previously been proven free from arsenic by having been subjected, *alone*, to the test about to be described, during at least two hours, with negative result. Now add the liquid to be tested, which must not contain any free acid nor very materially increase the volume of the contents of the test-tube. Immediately secure over the mouth of the test-tube a previously prepared cap made of 3 thicknesses of pure filter-paper free from dust, and apply to the upper filter-paper a drop of a saturated, aqueous solution of silver nitrate acidulated with nitric acid. (See Silver Nitrate Test-solution.) Then place the tube at once, upright, into a box containing sand heated to about 90° C. (194° F.), and fitted with a cover, so as to exclude light and dust, and permit the reaction to proceed for such a time as may be specially prescribed in each case. The presence of arsenic (but not of antimony) is revealed by the production, upon the moistened paper cap, of a brown or black stain. In absence of arsenic, if the test has been carefully conducted, the spot will remain colorless.

In place of zinc, metallic aluminum, best in form of wire cut into small pieces, may be employed (Gatehouse's modification). The method of testing and the results are the same as in Fleitmann's test.

Arsenic Test, Gutzeit's.—(See page 248.)

Barium Carbonate.—Purified barium carbonate, $BaCO_3$, is prepared by dissolving 12 parts of purified, crystallized barium chloride in 30 parts of boiling water, then adding 5 parts of ammonium carbonate, followed by 5 parts of ammonia-water; finally washing the precipitate thoroughly and drying.

Barium Chloride Test-solution.—Prepared from pure barium chloride. The aqueous solution of the salt should be perfectly neutral, and should not yield a precipitate with hydrogen sulphide or ammonium sulphide (absence of metals, etc.). The aqueous solution, after being precipitated by diluted sulphuric acid in slight excess, yields a filtrate which should not leave any permanent residue when evaporated and heated on platinum-foil (absence of other fixed bases and salts). Diluted alcohol, after remaining in contact with it for several hours, should, upon ignition, show a pure yellowish-green colored flame, without red streaks (absence of traces of strontium). To prepare the test-solution, dissolve 10 Gm. of the salt in enough water to make 100 Cc.

Barium Hydroxide Test-solution.—A saturated solution of barium hydroxide in water. This solution rapidly absorbs carbon dioxide from the air. It is preferably prepared freshly as wanted.

Barium Nitrate Test-solution.—Prepared from pure barium nitrate. This salt should respond to the same tests as barium chloride. In addition, its aqueous solution, slightly acidulated with nitric acid, should not be rendered turbid by silver nitrate (absence of chloride). To prepare the test-solution dissolve 10 Gm of the salt in water to make 100 Cc.

Benzin, or Petroleum Benzin.—Use the official purified petroleum benzin (*Benzinum Purificatum*, U. S. P.).

Benzene, or Benzol.—Benzene, C_6H_6, is a colorless, transparent liquid of a peculiar, aromatic odor, specific gravity 0.871 at 25° C. (77° F.), congealing at 5.2° C. (41.3° F.), and boiling at 80.4° C. (176.7° F.). It is insoluble in water, but soluble in 4 parts of alcohol, and in ether. When equal volumes of benzene and concentrated sulphuric acid are mixed, the latter should not become colored. On shaking 2 Cc. of benzene with 0.5 Cc. of sulphuric acid and 1 drop of fuming nitric acid, no green or blue tint should be produced (absence of thiophene).

Brazil-wood Test-solution.—See under Indicators.

Bromine-water (Bromine Test-solution).—An aqueous solution of bromine prepared by dissolving 1 Cc. of bromine in enough water to make 100 Cc.

Calcium Chloride Test-solution.—Dissolve 10 Gm. of crystallized calcium chloride in enough water to make 100 Cc.

Calcium Hydroxide Test-solution (Lime-water).—Use the official lime-water (see p. 889).

Calcium Sulphate Test-solution.—Introduce pulverized transparent crystals of native gypsum (selenite), $CaSO_4 + 2H_2O$, into a flask filled with water, agitate at intervals for 12 hours, and decant the

clear, saturated solution when required. 1 part of gypsum requires, at 25° C. (77° F.), 378 parts of water for solution.

Carbon Disulphide.—Use the official carbon disulphide (see p. 369).

Chlorine-water (Chlorine Test-solution).—Use the official chlorine-water. Since it rapidly deteriorates by keeping, it should be frequently renewed or freshly prepared when required.

Chloroform.—Use the official chloroform (see p. 410).

Cobaltous Nitrate Test-solution.—The crystallized, commercial salt is sufficiently pure if, after it is dissolved in water and the cobalt completely precipitated by ammonium sulphide, the filtrate leaves no residue on evaporation. To make the test-solution dissolve 1 Gm. of the salt in 10 Cc. of water.

Cochineal Test-solution.—See under INDICATORS.

Copper (Metallic Copper), in form of wire, foil, or turnings.

Cupric Ammonium Sulphate Test-solution.—A solution of cupri-tetrammonium sulphate, $Cu(NH_3)_4SO_4 + H_2O$. To copper sulphate test-solution add ammonia-water until the precipitate first formed is nearly, but not completely, redissolved; then filter. This solution should be freshly made when required.

Cupric Sulphate Test-solution.—Dissolve 10 Gm. of cupric sulphate in enough water to make 100 Cc.

Cupric Tartrate Test-solution.—See under VOLUMETRIC SOLUTIONS.

Diphenylamine Test-solution.—Prepared from diphenylamine, $(C_6H_5)_2NH$, which is in the form of grayish-white or colorless crystals of a peculiar, aromatic odor, melting at 54° C. (129.2° F.), slightly soluble in water, more soluble in acids. It is used either in the dry state, or in solution in diluted sulphuric acid, as a test for nitric acid (in sulphuric acid, water, etc.), or for chlorine (in hydrochloric acid). To test a solution for the presence of nitric acid, a small portion of it is mixed with 1 or 2 drops of diphenylamine test-solution, and then concentrated sulphuric acid, free from compounds of nitrogen, is poured in so as to form a layer beneath the solution. The presence of nitric acid is shown by a deep blue color at the zone of contact. A similar reaction is also produced by the presence of hypochlorites, chlorates, chromium trioxide, ferric salts, and similar oxidizing agents. The test solution is prepared by dissolving 0.1 Gm. of diphenylamine in 50 Cc. of diluted sulphuric acid. The solution should be colorless.

Ether.—Use the official ether. It should be strictly neutral to litmus-paper.

Ferric Ammonium Sulphate Test-solution.—Dissolve 10 Gm. of ferric ammonium sulphate in enough water to make 100 Cc.

Ferric Chloride Test-solution.—Dissolve 10 Gm. of ferric chloride in enough water to make 100 Cc.

Ferrous Sulphate Test-solution.—Dissolve a clear crystal of ferrous sulphate in about 10 parts of water previously boiled to expel air. This solution should be freshly prepared immediately before use.

Ferrous Sulphide.—A heavy solid, in form of black or brownish-black irregular masses or fused into sticks, soluble in sulphuric or hydrochloric acid with copious evolution of hydrogen sulphide.

Gelatin Test-solution.—Dissolve 1 Gm. of purified gelatin in 50 Cc. of water by the aid of a gentle heat, and filter if necessary. This solution should be freshly made when wanted for use.

Gold Chloride Test-solution.—The commercial chloride of gold, usually prepared by dissolving gold in nitro-hydrochloric acid and carefully evaporating to dryness, mostly consists of aurochloric acid, $HAuCl_4 + 2H_2O$, which is converted into neutral auric chloride, $AuCl_3$, by fusing it at a temperature not exceeding 150° C. (302° F.), moistening the residue (now consisting of auric and aurous chloride) with enough hot water to produce a syrupy liquid (whereby the aurous chloride is decomposed into auric chloride and metallic gold), and then pouring off the clear liquid from the precipitate. To prepare the test-solution dissolve the liquid finally obtained in the before-mentioned process in 20 volumes of water. Or dissolve 1 Gm. of dry auric chloride in 30 Cc. of water.

Hydrochloric Acid, Pure.—In addition to the tests prescribed for this acid by the Pharmacopœia, it is required to conform to the following more rigorous tests before it can be employed as a reagent: The addition of 1 Cc. of barium chloride test-solution to 1 Cc. of the acid diluted with 9 Cc. of water should cause no turbidity within 24 hours (absence of sulphuric acid). A crystal of diphenylamine dropped into the acid should not turn blue (absence of free chlorine). On substituting it for sulphuric acid in Gutzeit's test (see p. 248), no color should be imparted to the silver nitrate within 2 hours (absence of arsenic or antimony).

Hydrogen Sulphide.—A gas generated by treating ferrous sulphide with diluted sulphuric acid, and washing the gas by passing it through water.

Hydrogen Sulphide Test-solution (Hydrosulphuric Acid).—A saturated, aqueous solution of hydrogen sulphide. To prepare about 1000 Cc. of the solution, treat 20 Gm. of ferrous sulphide, in a suitable apparatus, with a mixture of 20 Cc. of sulphuric acid (U. S. P.), and 250 Cc. of water, pass the gas through a drying-tube filled with granulated calcium chloride, then from this through a tube of about 8 millimeters diameter and 40 centimeters in length, which contains about 5 Gm. of coarsely pulverized iodine mixed with spun glass (glass wool), and finally through a wash bottle which contains a small quantity of potassium iodide test-solution. The gas thus purified is conducted nearly to the bottom of a bottle of the capacity of about 1500 Cc., containing 1000 Cc. of cold water. The bottle should be shaken occasionally to facilitate the solution of the gas. When it is no longer absorbed, transfer the solution to small, dark amber-colored bottles, to be filled nearly to the top; pass a stream of hydrogen sulphide for a few minutes through each, and then at once stopper them tightly, and preserve them afterward in a cool and dark place. Before any of the solution is used it should be ascertained that it retains a strong odor of hydrogen sulphide, and that, when it is added to an equal volume of ferric chloride test-solution, a copious precipitate of sulphur is formed at once.

Indigo Test-solution.—Place 6 Gm. (3.3 Cc.) of fuming sulphuric acid into a beaker well cooled by immersion in water, and stir into it very gradually 1 Gm. of finely-powdered Bengal indigo. Set the mixture aside for 2 days, then pour it into 20 Cc. of water, and decant. Or dissolve 1 Gm. of commercial indigo-carmine (the sodium or potassium salt of sulphindigotic acid) in 150 Cc. of water.

Iodine Absorption Value of Fats and Oils.—The iodine value or number of a fat or an oil is a figure which indicates the percentage of iodine absorbed under certain conditions. It is determined as follows: To a solution of 0.3 Gm.[1] of the fat or oil in 10 Cc. of chloroform contained in a glass-stoppered bottle of

[1] 0.15 to 0.2 Gm. for linseed oil and 0.8 Gm. for oil of theobroma and similar fats.

250-Cc. capacity, add 25 Cc. of a mixture of equal volumes of alcoholic iodine test-solution, and alcoholic mercuric chloride test-solution, both of which have been measured from a burette. After having been securely stoppered, the bottle is set aside in a cool place, protected from the light, for a period of 4[1] hours. After this time, the mixture must still possess a brown color; if it does not, a further measured portion of the mixture of the two reagents should be added, and the mixture be again set aside. Finally, 20 Cc. of potassium iodide test-solution are added, followed by 50 Cc. of water, and tenth-normal sodium thiosulphate volumetric solution is then added in small successive portions, shaking thoroughly after each addition until the color of the mixture is discharged. The number of Cc. of the sodium thiosulphate volumetric solution consumed is noted. At the same time that this test is carried out a blank experiment is made in which exactly the same quantities of chloroform, iodine test-solution, and mercuric chloride test-solution are mixed, and after standing for 3 or more hours, the free iodine is estimated by titration with tenth-normal sodium thiosulphate volumetric solution as directed above. The number of Cc. of the thiosulphate volumetric solution consumed is noted, and from this is deducted the number of Cc. of the thiosulphate volumetric solution which was consumed in the test; the difference multiplied by 12.59, and this product divided by 3,[2] gives the iodine value of the fat or oil.

Iodine Test-solution.—For preparing the ordinary test-solution (as a reagent for starch, alcohol by iodoform test, etc.) iodine fulfilling the requirements of the Pharmacopœia is sufficiently pure. For this purpose dissolve 1 Gm. of iodine and 3 Gm. of potassium iodide in 50 Cc. of water.

For use in volumetric analysis, or in other cases where the ordinary impurities present in official iodine are objectionable, Purified Iodine must be employed.

Iodine Test-solution, Alcoholic.—Dissolve 25 Gm. of iodine in 500 Cc. of alcohol. This solution is employed in the determination of the iodine absorption value of fats and oils.

Iron, Metallic.—Bright and perfectly clean iron in the form of wire, sheet, or filings, according to the uses to be made of it. For making solutions of pure iron salts, fine, thin, bright wire (so-called florists' wire) should be used. For detecting copper, bright pieces of sheet-iron or knitting-needles are used; for detecting nitric acid by reduction to ammonia, iron-filings are preferable.

Lead Acetate Test-solution.—Dissolve 10 Gm. of clear, transparent crystals of lead acetate, free from adhering lead carbonate, in enough water to make 100 Cc. Preserve the solution in well-stoppered bottles.

Lead Acetate Test-solution, Basic.—Use the official solution of lead subacetate.

Litmus-paper and Test-solution.—See under INDICATORS.

Magnesia Mixture.—Dissolve 10 Gm. of magnesium sulphate and 20 Gm. of ammonium chloride in 80 Cc. of water, add 42 Cc. of ammonia-water, set the mixture aside for a few days in a well-stoppered vessel, and filter. It should never be used freshly made.

Magnesium Sulphate Test-solution.—Dissolve 10 Gm. of magnesium sulphate in enough water to make 100 Cc.

Mercuric Chloride Test-solution.—Dissolve 5 Gm. of mercuric chloride in enough water to make 100 Cc.

Mercuric Chloride Test-solution, Alcoholic.—Dissolve 30 Gm. of mercuric chloride in 500 Cc. of alcohol. This solution is employed in the determination of the iodine absorption value of fats and oils.

Mercuric Nitrate Test-solution, $Hg(NO_3)_2 + 4H_2O$.—Use the official solution of mercuric nitrate (*Liquor Hydrargyri Nitratis*, U. S. P.).

Mercuric Potassium Iodide Test-solution (*Mayer's Reagent*).—Dissolve 1.344 Gm. of mercuric chloride in 60 Cc. of water, and 5 Gm. of potassium iodide in 10 Cc. of water. Mix the two solutions, and then add sufficient water to make the mixture measure 100 Cc.

Mercuric Potassium Iodide Test-solution, Alkaline (*Nessler's Reagent*).—Dissolve 10 Gm. of potassium iodide in 10 Cc. of water, and add gradually, in portions, a saturated aqueous solution of mercuric chloride, with constant agitation, until a slight red precipitate remains undissolved; to this mixture add 30 Gm. of potassium hydroxide and, when solution has taken place, 1 Cc. more of the saturated aqueous solution of mercuric chloride. Dilute this solution with water until it measures 200 Cc. Allow the precipitate to subside, and draw off the clear fluid.

NOTE.—2 Cc. of this reagent, when added to 50 Cc. of water containing 0.05 milligramme of ammonia, should produce at once a yellowish brown coloration.

Mercurous Nitrate Test-solution, $Hg_2(NO_3)_2 + 2H_2O$.—Into a porcelain capsule put 1 Gm. of pure mercury with 0.5 Cc. of pure nitric acid and 0.5 Cc. of distilled water, and place it for 24 hours in a cool, dark room. Separate and drain the crystals, and dissolve them in 10 Cc. of water. Preserve the solution in a dark amber-colored bottle, into which a small globule of mercury has been placed.

Methyl Alcohol, CH_3OH.—For the identification of salicylic acid, the rectified, commercial wood-alcohol, having a specific gravity of about 0.820, is sufficiently pure, if it forms a clear, transparent mixture with an equal volume of distilled water.

Methyl-orange Test-solution.—See under INDICATORS.

Naphthylamine Acetate Test-solution, $C_{10}H_7NH_2.HC_2H_3O_2$.—Boil 0.1 Gm. of alpha-naphthylamine acetate in 20 Cc. of distilled water, filter through cotton, and mix the filtrate with 180 Cc. of diluted acetic acid (10 per cent. absolute acid). Only freshly distilled water should be employed in preparing this reagent, which must be kept in well-stoppered bottles, protected from the light.

Nitric Acid, Pure.—Use the official nitric acid.

Fuming Nitric Acid (Red Fuming Nitric Acid).—The commercial acid will answer, if it is of specific gravity of 1.450 or over. It should be carefully kept in glass-stoppered bottles in a cool place.

Oxalic Acid, Pure, $H_2C_2O_4 + 2H_2O$.—Pure oxalic acid is in the form of colorless, transparent, clinorhombic crystals; 10 Gm. on ignition upon platinum foil should leave no residue. One part of the acid is completely soluble in 12 parts of water at 25° C. (77° F.). For the preparation of test and volumetric solutions, commercial oxalic acid should be purified as follows:

To 1 part of the acid add 10 parts of cold water, and shake until the latter is saturated. Filter off the solution from the undissolved crystals, evaporate the filtrate to about ¾ of its volume, and set it

[1] Sixteen hours are required for accuracy in the case of linseed oil.

[2] When the quantity of the fat or oil used is not 0.3 Gm., then the product is not divided by 3, but by the figure corresponding to the quantity taken; thus, for linseed oil, 0.15 Gm. would be divided by 1.5.

aside so that the fixed salts which it contains may crystallize out. Carefully decant the liquid from the crystals, concentrate it by evaporation, and set it aside to crystallize, stirring occasionally to prevent the formation of large crystals which might enclose moisture. Drain the crystals in a funnel, dry them carefully on blotting-paper, and preserve them in well-stoppered bottles.

Oxalic Acid Test-solution.—Dissolve 10 Gm. of pure oxalic acid, $H_2C_2O_4 + 2H_2O$, in sufficient distilled water to measure 100 Cc.

Palladous Chloride Test-solution.—Dissolve 0.5 Gm. of palladous chloride, $PdCl_2$, in sufficient water to measure 10 Cc. Preserve in a glass-stoppered bottle.

Phenolphthalein Test-solution.—See under INDICATORS.

Picric Acid Test-solution.—Dissolve 1 Gm. of pure, distinctly crystalline picric acid (trinitrophenol), $C_6H_2(NO_2)_3OH$, in 100 Cc. of water, cool the solution, and filter, if necessary.

Platinic Chloride Test-solution.—Dissolve 2.6 Gm. of chloroplatinic acid, $H_2PtCl_6 + 6H_2O$, in 20 Cc. of water. On evaporating a small portion of the solution to dryness and igniting the residue, pure metallic platinum should remain, which should yield nothing soluble in nitric acid.

Potassium Bitartrate, $KHC_4H_4O_6$.—The purification of potassium bitartrate, to render it suitable for standardizing volumetric solutions of potassium and sodium hydroxide, is carried out as follows: To 100 Gm. of the salt contained in a beaker is added a mixture of 85 Cc. of water and 25 Cc. of diluted hydrochloric acid; the beaker is then placed upon a bath of boiling water and the mixture digested, with occasional stirring, for about 3 hours. After quickly cooling, the solution is drained off from the precipitate, which is washed by affusion and decantation with two successive portions of 100 Cc. each of water; after collecting the precipitate upon a plain filter, the washing with cold water is continued until the filtrate, after adding a few drops of nitric acid, ceases to become opalescent upon the addition of silver nitrate test-solution. The precipitate of potassium bitartrate is then dissolved in the smallest possible volume of boiling water (about 1500 Cc.), filtered, and the filtrate, while being rapidly cooled, is constantly stirred. When the mixture is cold, the crystalline precipitate is collected upon a plain filter, washed with 300 Cc. of cold water, and, after thoroughly draining, dried at 120° C. (248° F.) until of constant weight. It should be kept in dry, securely stoppered bottles.

Purified potassium bitartrate is employed for standardizing normal and tenth-normal potassium or sodium hydroxide volumetric solution.

Potassium Bromate, $KBrO_3$.—White cubical crystals or granular crystalline powder having a pungent, saline taste. Soluble in 15.5 parts of water at 25° C. (77° F.) and in 2 parts of boiling water; slightly soluble in alcohol. The aqueous solution has a neutral reaction, and upon the addition of diluted sulphuric acid no yellow color should at once be produced. When heated to 350° C. (662° F.) the salt undergoes decomposition with evolution of oxygen. Potassium bromate should not be triturated or heated with organic or easily oxidizable substances. The addition of nitric acid or sulphuric acid to the salt causes decomposition with evolution of bromine. If 0.1 Gm. of potassium bromate, dried at 100° C. (212° F.), and 2 Gm. of potassium iodide be dissolved in about 25 Cc. of water contained in a glass-stoppered bottle (of about 100 Cc. capacity) and, after the addition of 5 Cc. of hydrochloric acid, the bottle be securely stoppered and set aside for half an hour, not less than 36.1 Cc. of tenth-normal sodium thiosulphate volumetric solution should be required to discharge the color, corresponding to 99.8 per cent. of pure potassium bromate.

Potassium Carbonate Test-solution.—Dissolve 10 Gm. of anhydrous potassium carbonate, prepared by heating potassium carbonate to 130° C. (266° F.), in sufficient water to measure 100 Cc.

Potassium Chromate Test-solution.—Dissolve 10 Gm. of yellow potassium chromate in sufficient water to measure 100 Cc. On adding silver nitrate test-solution to a few drops of the solution diluted with a little distilled water, a red precipitate is produced which should be completely soluble in nitric acid (absence of chloride). Another portion of the solution, mixed with an equal volume of diluted hydrochloric acid, should yield no precipitate with barium chloride test-solution (absence of sulphate). Another portion of the solution should not become turbid upon the addition of ammonia-water or ammonium oxalate test-solution (absence of alkaline earths). A solution of 0.1 Gm. of the salt in 20 Cc. of water should not become red upon the addition of a few drops of phenolphthalein test-solution (limit of free alkalies).

Potassium Cyanide Test-solution.—Dissolve 1 Gm. of potassium cyanide in sufficient water to measure 10 Cc. This solution should be freshly prepared when required.

Potassium Dichromate, Pure, $K_2Cr_2O_7$.—In addition to the tests prescribed for this salt in the text of the Pharmacopœia, it is required to conform to more rigorous tests before it can be used in the preparation of the tenth-normal volumetric solution. In a solution of 0.5 Gm. of the salt in 10 Cc. of water rendered acid by 0.5 Cc. of nitric acid, no turbidity should be produced by barium chloride test-solution (absence of sulphates).

To 10 Cc. of the aqueous solution of the salt (1 in 20), the addition of 1 Cc. of ammonia-water, followed by 1 Cc. of ammonium oxalate test-solution, should produce no turbidity (absence of calcium).

If to a solution of 0.5 Gm. of the salt in 20 Cc. of water sufficient sulphurous acid be added to impart a strong odor of the reagent, and the mixture be boiled for about 3 minutes and cooled, the addition of 1 Cc. of nitric acid and a few drops of silver nitrate volumetric solution should produce no turbidity (absence of chlorides).

Potassium dichromate which fails to meet all of the above requirements may be purified by recrystallization, the hot, saturated aqueous solution of the salt being rapidly cooled with agitation. The granular crystals, after being collected on a plain filter and washed with sufficient cold water to remove the mother-liquor, are thoroughly drained and then dried at 120° C. (248° F.). This recrystallization should be repeated until the salt responds to all the above tests for purity.

Potassium Dichromate Test-solution.—Dissolve 10 Gm. of pure potassium dichromate in sufficient water to measure 100 Cc.

Potassium Ferricyanide Test-solution.—Dissolve 1 part of potassium ferricyanide in about 10 parts of water. This solution should be made freshly when required, as it is rapidly decomposed by light. A freshly prepared, aqueous solution, when mixed with some ferric chloride test-solution and diluted with water, should show a brown tint, free from turbidity or a shade of green.

Potassium Ferrocyanide, $K_4Fe(CN)_6 + 3H_2O$.—In the form of large, soft, transparent, yellow, four-sided, monoclinic tables, odorless, and having a mild, saline taste. Slightly efflorescent on exposure to dry air.

Soluble in 3 parts of water at 25° C. (77° F.) and in 2 parts of boiling water; insoluble in alcohol. The aqueous solution is neutral to litmus-paper. No effervescence should be caused by the addition of diluted sulphuric acid to a concentrated solution of the salt (absence of carbonate).

The aqueous solution (1 in 20), acidulated with hydrochloric acid, should, upon the addition of barium chloride test-solution, remain clear (absence of sulphate). If a mixture of 0.5 Gm. of the salt with 1.5 Gm. of pure potassium nitrate and 0.5 Gm. of pure anhydrous sodium carbonate be heated to redness in a porcelain crucible, the residue dissolved in water, and the filtered solution supersaturated with nitric acid, no turbidity should be produced upon the addition of silver nitrate test-solution (absence of chloride). The precipitate produced in the aqueous solution, acidulated with nitric acid by silver nitrate test-solution, should be of a pure white color, without a tinge of red (absence of ferricyanide).

Potassium Ferrocyanide Test-solution.—Dissolve 10 Gm. of potassium ferrocyanide, $K_4Fe(CN)_6 + 3H_2O$, in sufficient water to measure 100 Cc.

Potassium Hydroxide Test-solution.—Use the official solution of potassium hydroxide (see page 913). For use in Fleitmann's test for arsenic (see above), it should have previously been subjected, by itself, to this test for at least 2 hours, with negative result (absence of arsenic).

Potassium Hydroxide Test-solution, Alcoholic.—Use the half-normal alcoholic potassium hydroxide volumetric solution. (See SAPONIFICATION VALUE OF FATS AND OILS.)

Potassium Iodide Test-solution.—Dissolve 20 Gm. of official potassium iodide in enough water to make 100 Cc., and keep the solution in dark amber-colored, well-stoppered bottles to prevent the formation of iodate. The solution should be frequently renewed, or freshly prepared when required.

Potassium Nitrate.—The dry salt responding to the tests of purity required by the Pharmacopœia, particularly to those for absence of chloride and sulphate.

Potassium Permanganate Test-solution.—Use the tenth-normal volumetric solution.

Potassium Sulphate Test-solution.—Dissolve 1 Gm. of official potassium sulphate in enough water to make 100 Cc.

Potassium Sulphocyanate, KSCN.—Colorless, prismatic crystals, of cooling, saline taste, and hydroscopic in moist air. Readily soluble in less than its own weight of water; soluble in 10 parts of absolute alcohol.

The aqueous solution of the salt (1 in 20) should not become turbid within 5 minutes upon the addition of barium chloride test-solution (limit of sulphate).

The aqueous solution (1 in 20), after the addition of 1 Cc. of diluted hydrochloric acid, should remain colorless (absence of iron), and should not respond to the time-limit test for heavy metals (see below).

Potassium Sulphocyanate Test-solution.—Use the tenth-normal volumetric solution.

Resins, etc., Acid Number for.—Dissolve 1 Gm. of the resinous substance in alcohol, add a few drops of phenolphthalein test-solution, and titrate with normal potassium hydroxide volumetric solution, the amount of potassium hydroxide consumed (expressed in milligrammes) is termed the acid number. The reaction is often more distinct if an excess of normal potassium hydroxide volumetric solution be used and the solution titrated back with normal acid volumetric solution.

Saponification Value of Fats and Oils.—The determination of the saponification value is conducted as follows: Weigh out accurately, in a flask holding 150 to 200 Cc., 1.5–2 Gm. of the purified and filtered fat. Next run into the flask, with a burette, 25 Cc. of alcoholic potassium hydroxide test-solution (see above). While exactly 25 Cc. is not indispensable, in comparative tests precisely the same amount must be used, allowing the burette to drain in exactly the same way in each test. Then place a small funnel in the flask and heat it on a water-bath containing boiling water, for half an hour, so that the alcohol is simmering, frequently imparting a rotary motion to the contents of the flask. Then add 1 Cc. of phenolphthalein test-solution, and titrate back the excess of potassium hydroxide with half-normal hydrochloric acid volumetric solution. A blank test is made at the same time, using the alcoholic potassium hydroxide test-solution alone; the difference in the number of cubic centimeters of half-normal hydrochloric acid volumetric solution consumed by the blank test and the real test, multiplied by 27.87, and divided by the weight in grammes of the fat or oil, will give the saponification equivalent of the sample tested.

Silver Ammonium Nitrate Test-solution.— Dissolve 1 Gm. of official silver nitrate in 20 Cc. of water, and add ammonia-water drop by drop, until the precipitate first produced is almost, but not entirely, redissolved. Filter the solution, and preserve in dark amber-colored and well-stoppered bottles.

Silver Nitrate Test-solution.—For ordinary purposes use the tenth-normal volumetric solution.

Silver Sulphate Test-solution.—Dissolve 1 Gm. of official silver nitrate in 0.5 Cc. of warm water, and add 1.5 Cc. of pure, concentrated sulphuric acid. On cooling, small transparent crystals of silver sulphate separate. Carefully pour off the acid liquid, wash the crystals repeatedly, by decantation, with cold water, transfer them to a bottle, add 100 Cc. of water, and agitate so as to produce a saturated solution. For use decant a sufficient quantity of the latter.

Sodium Acetate Test-solution.—Dissolve 10 Gm. of official sodium acetate in enough water to make 100 Cc.

Sodium Bitartrate Test-solution, $NaHC_4H_4O_6 + H_2O$.—To a solution of 2.4 Gm. of tartaric acid in about 80 Cc. of boiling water, add gradually, in small portions, monohydrated sodium carbonate until the solution has a neutral reaction; to this liquid is now added 3.5 Gm. of tartaric acid, and after filtering and cooling, sufficient water is added to the solution to measure 100 Cc. This solution should be freshly prepared when required.

Sodium Carbonate.—The monohydrated salt, $Na_2CO_3 + H_2O$, conforming to the tests prescribed by the Pharmacopœia, but absolutely free from chloride and sulphate.

Sodium Carbonate Test-solution.—Dissolve 10 Gm. of monohydrated sodium carbonate in sufficient water to measure 100 Cc.

Sodium Cobaltic Nitrite Test-solution, $CO_2(NO_2)_6 6NaNo_2 + H_2O$.—Dissolve 4 Gm. of cobaltous nitrate, $Co(NO_3)_2 + 6H_2O$, and 10 Gm. of sodium nitrite, $NaNO_2$, in about 50 Cc. of water, add 2 Cc. of acetic acid, and dilute with enough water to make 100 Cc. Should any of the nitrous acid be lost by keeping the solution, a few drops of acetic acid may be added.

Sodium Hydroxide Test-solution.—Use the official solution of sodium hydroxide (see page 917).

Sodium Nitrite, $NaNO_2$.—The purest commercial salt, generally in form of pencils, is sufficiently pure.

Sodium Nitro-prusside Test-solution.—Dissolve 1 part of sodium nitro-prusside, $Na_2Fe(NO)(CN)_5 + 2H_2O$, in 19 parts of water immediately before using.

Sodium Phosphate Test-solution.—Dissolve 10 Gm. of official sodium phosphate, $Na_2HPO_4 + 12H_2O$, in enough water to make 100 Cc.

Sodium Tartrate Test-solution, $Na_2C_4H_4O_6 + 2H_2O$.—To a solution of 6.5 Gm. of tartaric acid in about 80 Cc. of boiling water, add gradually, in small portions, monohydrated sodium carbonate until the solution has a neutral reaction; after filtering and cooling, add sufficient water to measure 100 Cc. This solution should be freshly prepared when required.

Sodium Thiosulphate, $Na_2S_2O_3 + 5H_2O$.—In addition to the tests prescribed for this salt in the text of the Pharmacopœia, it is required to conform to the following more rigorous tests before it can be used in preparing the standard volumetric solution. If to a solution of the salt (1 in 20) in distilled water iodine test-solution be added, drop by drop, until it retains a faint but permanent brown color, no turbidity should be produced upon the addition of barium chloride test-solution (absence of sulphates and sulphites). The addition of 1 drop of phenolphthalein test-solution to the aqueous solution of the salt (1 in 10) should produce not more than a very faint rose tint (absence of free alkalies). The aqueous solution of the salt (1 in 20) should not become cloudy upon the addition of ammonium oxalate test-solution (absence of calcium salts).

Sodium Thiosulphate Test-solution.—Use the tenth-normal volumetric solution.

Stannous Chloride Test-solution.—Heat pure tin, in form of foil or granules, with concentrated hydrochloric acid, taking care that the metal be in excess. When the acid is saturated, crystals of stannous chloride, $SnCl_2 + 2H_2O$, begin to form. Remove and drain these, dissolve them in 10 parts of water, and preserve the solution in well-stoppered bottles, into each of which a granule of pure tin or a piece of pure tin-foil has previously been introduced.

For Bettendorf's test (see p. 249) pure concentrated hydrochloric acid is saturated with the freshly-prepared crystals.

Starch Test-solution.—Mix 1 Gm. of starch with 10 Cc. of cold water, and then add enough boiling water, with constant stirring, to make about 200 Cc. of a thin, transparent jelly. If it is desired to preserve this test-solution for any length of time, 10 Gm. of zinc chloride, $ZnCl_2$, should be added to it and the solution transferred to small bottles, which should be well-stoppered.

Sulphanilic Acid Test-solution.—Dissolve 0.5 Gm. of sulphanilic acid, $HC_6H_4(NH_2)SO_3$ (para-amido-benzenesulphonic acid), in 150 Cc. of diluted acetic acid (10 per cent. absolute acetic acid). Only freshly distilled water should be employed in preparing the diluted acetic acid.

This reagent should be kept in well-stoppered bottles.

Sulphuric Acid, Pure, for Tests, H_2SO_4.—The sulphuric acid of the Pharmacopœia, which has a specific gravity of 1.826 at 25° C. (77° F.), will answer as a reagent for most purposes, provided it is of the required degree of purity. But when "concentrated" sulphuric acid is specially directed in a test, it is intended that the strongest obtainable pure acid, of a specific gravity of not less than 1.834 at 25° C. (77° F.), be employed.

In addition to the tests prescribed for this acid in the text of the Pharmacopœia, it is required to conform to the following more rigorous tests before it can be employed as a reagent. If 1 Cc. of diphenylamine test-solution be carefully poured, as a separate layer, upon 5 Cc. of sulphuric acid, contained in a test-tube, no distinct blue color should appear in the zone of contact (absence of nitric acid).

Tannic Acid Test-solution.—Dissolve 1 Gm. of tannic acid in 1 Cc. of alcohol and enough water to make 10 Cc., immediately before use.

Tartaric Acid Test-solution.—Dissolve 1 part of tartaric acid in 3 parts of water. Since fungous growths rapidly destroy the solution of tartaric acid, it should be prepared only as wanted.

Time-limit Test for Heavy Metals.—This general test is to be used to detect the presence of poisonous or undesirable metallic impurities in official chemical substances or their solutions.

Ten cubic centimeters of a solution of the salt or acid in distilled water (1 in 20), contained in a test-tube of about 40-Cc. capacity, when acidulated with 1 Cc. of diluted hydrochloric acid (unless otherwise directed), and warmed to about 50° C. (122° F.), should not be colored or rendered turbid by the addition of an equal volume of freshly prepared hydrogen sulphide test-solution, after standing, well-stoppered, in a warm place, 35° C. (95° F.), for at least half an hour, nor should the further addition of ammonia-water to this solution cause a coloration or turbidity therein.

Before the addition of the ammonia-water, the mixture should still possess the odor of hydrogen sulphide; if not, it should be thoroughly saturated with the gas and again set aside for half an hour.

Any change in the color of the solution which is being tested should be noted by comparison with a like volume of the hydrogen sulphide test-solution, when viewed by reflected light while held against a white surface.

ANTIMONY yields, upon the addition of hydrogen sulphide test-solution to highly diluted solutions, a pale yellow to orange color, or, to more concentrated solutions, an orange precipitate, which is soluble in test-solutions of potassium hydroxide and ammonium sulphide, as well as in strong hydrochloric acid.

The precipitate is insoluble in test-solution of ammonium carbonate. The addition of ammonia-water to the highly diluted hydrogen sulphide solution of antimony slightly intensifies the coloration.

ARSENIC yields, upon the addition of hydrogen sulphide test-solution to highly diluted solutions, a pale-yellow color, or, to more concentrated solutions, a yellow precipitate, which is soluble in test-solutions of potassium hydroxide, ammonium sulphide, and ammonium carbonate, but is reprecipitated upon the addition of hydrochloric acid, insoluble in excess. The addition of ammonia-water to the highly-diluted hydrogen sulphide solution of arsenic slightly intensifies the yellow color.

CADMIUM in very dilute solutions gives, with hydrogen sulphide test-solution or ammonium sulphide test-solution, a pale-yellow color; it yields in more concentrated solutions (not excessively acid) a yellow precipitate, which is insoluble in cold diluted hydrochloric acid, potassium hydroxide test-solution, or ammonium sulphide test-solution (distinction from arsenic), and in solution of potassium cyanide. This precipitate is soluble in nitric and hydrochloric acids and in hot diluted hydrochloric and sulphuric acids.

COPPER yields, upon the addition of hydrogen sulphide test-solution to highly diluted solutions, a pale-brown color, or, to more concentrated solutions, a brownish-black precipitate, which is insoluble in

diluted hydrochloric acid and test-solution of potassium hydroxide, and is but very slightly soluble in test-solution of ammonium sulphide. The precipitate is soluble in warm diluted nitric acid, and also in solution of potassium or sodium cyanide. The addition of ammonia-water to the highly diluted hydrogen sulphide solution containing copper slightly intensifies the coloration.

IRON.—Acidified solutions of ferrous iron do not react with hydrogen sulphide test-solution, but yield a dark coloration or black precipitate with ammonium sulphide test-solution, or upon the addition of ammonia-water to the hydrogen sulphide mixture. This latter precipitate is soluble in cold diluted hydrochloric acid.

Acidified solutions of ferric iron yield a white turbidity or precipitate of sulphur upon the addition of hydrogen sulphide test-solution, but a dark coloration or black precipitate with ammonium sulphide test-solution, or upon the addition of ammonia-water to the hydrogen sulphide mixture. This precipitate is readily soluble in acetic and inorganic acids.

LEAD yields, upon the addition of hydrogen sulphide test-solution or ammonium sulphide test-solution to highly diluted solutions, a pale-brown coloration, or, to more concentrated solutions, a black precipitate, which is insoluble in diluted hydrochloric acid, and also in test-solutions of potassium hydroxide and ammonium sulphide.

ZINC yields, with ammonium sulphide test-solution, and with hydrogen sulphate test-solution, either in neutral solution or after acidulation with acetic acid (in the absence of free mineral acids), a white turbidity in highly diluted solutions, but with concentrated solutions a white precipitate soluble in hydrochloric acid and insoluble in acetic acid.

Tin.—Pure metallic tin, Sn, in the granulated or mossy condition. Its solution in hydrochloric acid should give no precipitate with potassium sulphate test-solution (absence of lead), and, when tested by the modified Gutzeit's test (see p. 248), replacing the zinc by tin, the diluted hydrochloric acid by hydrochloric acid, U. S. P., and adding 1 drop of platinic chloride test-solution, the mercuric chloride cap should not become colored within the time required for the solution of the metal (absence of arsenic).

Tumeric Paper and Tincture.—See under INDICATORS.

Zinc.—Metallic zinc, preferably in the form of thin pencils (about 5 Mm. in diameter), prepared by fusing the metal and casting it in molds, or in the form of thin sheets. It should respond to all the tests required by the Pharmacopœia, and in addition, when examined by Gutzeit's test, it should not cause the silver nitrate to become colored within 2 hours (absence of arsenic).

Zinc-Iodide-Starch Test-solution.—To 100 Cc. of freshly prepared starch test-solution add 5 Gm. of official zinc chloride and 3 Gm. of official zinc iodide. Preserve the colorless solution carefully in small, dark amber-colored and well-stoppered vials.

2. Indicators for Acidimetry, Alkalimetry, etc.

NOTE.—Each test-solution used as indicator should be examined as soon as prepared, and afterward, from time to time, as to its neutrality. If necessary, it should be brought, by the cautious addition of diluted sulphuric acid or of a dilute solution of an alkali, to such a point that, when a few drops of it are added to 25 Cc. of water, a single drop of a hundredth-normal acid or alkali solution, respectively, will distinctly develop the corresponding tints.

Since many of the colored test-solutions are injured by exposure to light, it is best to preserve them in dark, amber-colored vials. Papers prepared with them should be kept in dark bottles or paper boxes.

Brazil-wood Test-solution.—Boil 50 Gm. of finely-cut Brazil-wood [the heart-wood of Peltophorum dubium (*Sprengel*) *Britton*, nat. ord. Leguminosæ] with 100 Cc. of water during half an hour, replacing the water from time to time. Allow the mixture to cool, strain, wash the contents of the strainer with water until 100 Cc. of strained liquid are obtained, add 25 Cc. of alcohol, and filter. This solution turns purplish red with alkalies and yellow with acids.

Cochineal Test-solution.—Macerate 1 Gm. of unbroken cochineal during four days with 20 Cc. of alcohol and 60 Cc. of water. Then filter. The color of this test-solution turns violet with alkalies and yellowish red with acids. As an indicator it is used chiefly when ammonia or alkaline earths are present.

Hematoxylin Test-solution.—Dissolve 0.2 Gm. of hematoxylin [a crystalline substance derived from *Hæmatoxylon*, U. S. P.] in 100 Cc. of alcohol. Use about 5 drops for each titration. This indicator assumes a yellow to orange color in acid solutions, and a violet to purple color in alkaline solutions. The titration is complete when the change in color remains permanent upon the addition of 1 drop of the volumetric solution after stirring the liquid.

Iodeosin Test-solution.—Dissolve 0.1 Gm. of iodeosin, $C_{20}H_8I_4O_5$ (*tetraiodofluorescein*), in 100 Cc. of alcohol. This indicator becomes colorless in acid solutions, changing to pink in alkaline solutions. Dilute the solution to be titrated in a 200-Cc. flask with distilled water to about 100 Cc., add 20 Cc. of ether and 5 drops of the iodeosin test-solution, cork, and shake well. Then add the volumetric alkali solution gradually, shaking well after each addition. The titration is complete when the lower aqueous solution retains a faint pink color after shaking thoroughly. For assaying akaloidal residues, dissolve the latter in a measured excess of volumetric acid solution, and transfer the acid solution to a 200-Cc. flask, washing the container well with water until the contents of the flask measure about 100 Cc. Then proceed as above.

Litmus-paper and Test-solution.—Exhaust powdered litmus with three separate and successive portions (representing about 4 times its weight) of boiling alcohol (which removes the undesirable color erythrolitmin), each extraction lasting for about one hour. After draining off the alcohol, digest the residue with about an equal weight of cold water, and filter. (This blue solution, which contains some alkali, after being acidulated, may be used to make red litmus-paper.) Finally, extract the residue with about 5 times its weight of boiling water, and, after thoroughly cooling, filter. The addition of 1 drop of tenth-normal acid or alkali volumetric solution to 50 Cc. of water containing 5 drops of the indicator should produce a distinct change in color. Preserve the filtrate, as test-solution, in wide-mouthed bottles stoppered with loose plugs of cotton, so as to exclude dust but admit air. The blue color of litmus test-solution is changed by acids to red, and this red color by the addition of alkalies is restored to blue.

Litmus-paper, Blue.—Impregnate, with the test-solution just described, strips of white, unsized paper, free from wood-pulp, but not too porous, and dry them by suspending them on strings of clean twine.

Litmus-paper, Red.—Prepare this with the same kind of paper and in the same manner as described in the preceding paragraph. To impregnate the paper, either use the blue solution obtained from litmus, by treating the mass, after extraction of alcohol, with cold water, acidulating the same with just enough hydrochloric acid to impart to it a distinctly red tint; or use the regular test-solution, after acidulating it in the same manner.

Neither blue nor red litmus-paper should have a very intense color.

Preserve the test-paper in paper boxes or bottles, so as to exclude dust and acid or ammoniacal vapors.

Methyl-orange Test-solution.—Dissolve 1 Gm. of methyl-orange (the sodium or ammonium salt of dimethylamidoazobenzenesulphonic acid, $HC_{14}H_{14}N_3SO_3$; also known as helianthin, or tropæolin D, or Poirrier's Orange III.) in 1000 Cc. of water. Add to it carefully diluted sulphuric acid, in drops, until the liquid turns red and just ceases to be transparent. Then filter.

To distinguish methyl-orange from other orange colors of this class, which are unfit for use as indicators, it should respond to the following tests:

Methyl-orange should be completely soluble in distilled water, and the test-solution should be of an orange-yellow color, free from a brownish tint. No precipitate should form in this solution upon the addition of an alkali.

The addition of hydrochloric acid to a hot, concentrated solution of methyl-orange should produce a crystalline precipitate, composed of lustrous plates having a violet reflection and free from brown tint.

The addition of calcium chloride or barium chloride test-solution should produce no precipitate.

A few drops of gold chloride test-solution should produce a red coloration, free from either a violet or green tint.

Excessive quantities of this indicator should be avoided in titrating; from 1 to 3 drops are sufficient for a volume of from 50 to 100 Cc., or just enough is added to impart a faint tint to the solution, which if neutral should change to a red or yellow, respectively, upon the addition of 2 drops of tenth-normal acid or alkali volumetric solution.

Methyl-orange is suitable for titrating inorganic acids, alkalies, alkali carbonates or bicarbonates, also certain alkaloids, as morphine and quinine. It is not to be employed in titrating organic acids, nor in alcoholic or boiling solutions.

This indicator gives a yellow color with alkalies and red with acids.

Phenolphthalein Test-solution.—Dissolve 1 Gm. of phenolphthalein ($C_{20}H_{14}O_4$) in 50 Cc. of alcohol and dilute to 100 Cc. with water. About 3 drops are sufficient for 50 Cc. of the solution to be titrated; it gives a red color with alkali hydroxides or carbonates, while acids render the solution colorless. Phenolphthalein may be employed in hot titrations. It is not suitable as an indicator for ammonia, but is largely used for organic acids, alkali hydroxides, and for carbonates and bicarbonates in boiling solutions.

Phenolphthalein-paper is prepared by impregnating white, unsized paper with the test-solution and drying it.

Turmeric Tincture.—Digest any convenient quantity of ground turmeric root (from *Curcuma longa* Linné, Fam. *Zingiberaceæ*) repeatedly with small quantities of water and discard the liquids. Then digest the dried residue for several days with 6 times its weight of alcohol, and filter.

Turmeric-paper.—Impregnate white, unsized paper with the tincture, and dry it. The tincture, as well as the paper, turns brown with alkalies, and the original yellow color is restored by acids, with the exception of boric acid, which, even in the presence of hydrochloric acid, turns the color to reddish brown, and this is changed to bluish black by ammonia.

Rosolic Acid Test-solution.—Dissolve 1 Gm. of commercial rosolic acid [chiefly methylaurin, $C_{20}H_{16}O_3$] in 10 Cc. of diluted alcohol, and add enough water to make 100 Cc. The solution turns violet-red with alkalies, yellow with acids. In place of rosolic acid, commercial pæonin (also known as aurin R) [chiefly $C_{19}H_{14}O_3$] may be employed.

VOLUMETRIC SOLUTIONS.

NOTE.—It is absolutely necessary that the measuring vessels employed in the operations of volumetric analysis, consisting of burettes, flasks, mixing cylinders, pipettes, etc., should agree among themselves accurately in their graduation at the standard temperature selected. It is immaterial what standard temperature has been selected for the graduation of the vessels.

All volumetric solutions must be prepared at the standard temperature of 25° C. (77° F.), and the solutions must be used in the titrations at a temperature not below 21° C. (69.8° F.), nor above 29° C. (84.2° F.).

All bottles in which volumetric solutions are to be kept, as well as the burettes or pipettes in which they are to be measured, should, prior to use, be thoroughly rinsed with distilled water, then with 2 or 3 small portions of the solution that they are to contain. When not in use, burettes should be kept filled with distilled water.

Normal volumetric solutions are those which contain in 1 liter, in any stated reaction, the chemical equivalent of 1 gramme of hydrogen. If the molecule of the reagent is univalent, 1 liter will contain the weight in grammes equal to the molecular weight of the reagent; if bivalent, a weight in grammes equal to ½ its molecular weight; if trivalent, a weight in grammes equal to ⅓ its molecular weight.

Thus, hydrochloric acid, HCl = 36.18, having but 1 H atom replaceable by a basic element, has 36.18 Gm. of absolute HCl in 1000 Cc. of the normal volumetric solution; while sulphuric acid, H_2SO_4 = 97.35, having 2 replaceable H atoms, contains only ½ this number, or 48.675 grammes of absolute H_2SO_4 in 1000 Cc. of its normal solution. Potassium hydroxide, KOH = 55.74, has but 1 K to replace 1 H in acids, hence its normal solution contains 55.74 grammes of pure KOH in 1 liter. Again, 1 molecule of potassium dichromate in oxidation liberates 3 atoms of oxygen which are capable of oxidizing 6 atoms of ferrous to ferric iron. Therefore each molecule of the dichromate, yielding 3 atoms of oxygen, is equivalent to 6 atoms of hydrogen. Hence the normal solution should

contain $\frac{292.28}{6}$ or 48.713 Gm. in 1000 Cc. 2 Molecules of potassium permanganate, $2KMnO_4 = 313.96$, in oxidation, give off 5 atoms of O, which are equivalent to 10 atoms of H; hence its normal solution should contain $\frac{313.96}{10}$ or 31.396 Gm. in 1000 Cc.

Solutions containing in 1000 Cc. $\frac{1}{10}$ of the quantity of the active reagent in the normal solution are called tenth-normal; those containing $\frac{1}{100}$, hundredth-normal; $\frac{1}{50}$, fiftieth-normal; those containing twice the amount, double-normal; half the amount, half-normal.

Solutions containing quantities of the active reagent having no simple relation to the molecular weight are called empirical.

In the majority of the assays it has been directed that an integral quantity (1, 2, 5, or 10 Gm.) of the substance which is to be tested be weighed, dissolved in water, and made up to a definite volume, then an aliquot portion (representing the fractional weight of the substance required) is measured off for titration. Fractional parts of the Cc. may be measured by means of a 1-Cc. pipette graduated in $\frac{1}{10}$ or $\frac{1}{20}$ divisions.

Use of Empirical Solutions.—All standard volumetric solutions deteriorate in time, some very slowly, others rapidly, especially when not properly preserved. To restore the titer of such solutions (that is, to make them exactly normal, tenth- or hundredth-normal, as the case may be), each time they are to be used, involves an unnecessary waste of time. If one accurately standardized solution be always available, it is not necessary that the other volumetric solutions employed in conjunction with it be diluted to exactly correspond, Cc. for Cc., so long as the exact ratio is known.

The percentage strength of any empirical solution as compared with a standard volumetric solution is ascertained by experiment, then the number of Cc. of the empirical solution consumed in the titration of the substance is multiplied by its percentage strength, which result represents the equivalent volume of the true standard solution.

Example.—1 gramme of a sample of potassium carbonate required for neutralization 22 Cc. of an empirical solution of hydrochloric acid. In a trial experiment, 16 Cc. of this weak solution were required to neutralize 10 Cc. of a standard normal potassium hydroxide volumetric solution. The former is therefore of 62.5 per cent. strength (for $16 : 10 :: 100 : x$. $x = 62.5$), hence the 22 Cc. of empirical solution consumed represent 13.75 Cc. (62.5 per cent. of 22) of standard normal hydrochloric acid volumetric solution. Then if 1 Cc. of one-normal hydrochloric acid volumetric solution = 0.068635 Gm. of potassium carbonate, 13.75 Cc. would be equivalent to 13.75×0.068635, or 0.9436 + Gm. of carbonate.

Alkaline Cupric Tartrate Volumetric Solution, U. S. (*Fehling's Solution*).—*A. The Copper Solution.*—Dissolve 34.67 (34.6663) Gm. of carefully selected, small crystals of pure cupric sulphate, showing no trace of efflorescence or of adhering moisture, in a sufficient quantity of water to make the solution measure, at 25° C. (77° F.), exactly 500 Cc. Keep this solution in small, well-stoppered bottles.

B. The Alkaline Tartrate Solution.—Dissolve 173 Gm. of crystallized potassium and sodium tartrate and 75 Gm. of potassium hydroxide in a sufficient quantity of water to make the solution measure, at 25° C. (77° F.), exactly 500 Cc. Keep the solution in small, rubber-stoppered bottles.

For use, mix exactly equal volumes of the two solutions at the time required.

One Cubic Centimeter of the Mixed Solution is the equivalent of:

	Gramme.
Cupric sulphate, crystallized, $CuSO_4 + 5H_2O$	0.03467
Cupric tartrate, $CuC_4H_4O_6 + 3H_2O$	0.03688
Cane-sugar (Inverted)	0.00475
Glucose, anhydrous, $C_6H_{12}O_6$	0.00500
Milk-sugar, anhydrous, $C_{12}H_{22}O_{11}$	0.00678

Tenth-normal Bromine Volumetric Solution, U. S. (*Koppeschaar's Solution.*) (Br., 79.36; 7.936 Gm. in 1000 Cc.).—Dissolve 3.2 Gm. of potassium bromate and 50 Gm. of potassium bromide in sufficient water to measure, at or near 25° C. (77° F.), 900 Cc. Transfer 20 Cc. of this solution, by means of a pipette, into a bottle having a capacity of about 250 Cc. and provided with a glass stopper; add 75 Cc. of water and 5 Cc. of pure hydrochloric acid, and immediately insert the stopper. Shake the bottle a few times, then remove the stopper just sufficiently to quickly introduce 5 Cc. of potassium iodide test-solution, taking care that no bromine vapors escape, and immediately stopper the bottle. Agitate the bottle thoroughly, remove the stopper and rinse it and the neck of the bottle with a little water so that the washings flow into the bottle, and then add from a burette tenth-normal sodium thiosulphate volumetric solution until the brown iodine tint is just discharged. Note the number of Cc. of the sodium thiosulphate volumetric solution thus consumed, and then dilute the bromine solution so that equal volumes of it and of tenth-normal sodium thiosulphate volumetric solution will exactly correspond to each other under the conditions mentioned above.

Example.—Assuming that the 20 Cc. of the bromine solution have required 25.2 Cc. of the sodium thiosulphate volumetric solution to completely discharge the iodine tint, then each 20 Cc. of the bromine solution must be diluted to 25.2 Cc. Thus, if 850 Cc. of the solution remain, it must be diluted with water to measure 1071 Cc.

After the solution is thus diluted a new trial should be made in the manner above described, in which 25 Cc. of the tenth-normal sodium thiosulphate volumetric solution should just discharge the tint of the iodine liberated by the bromine set free from 25 Cc. of the standard bromine solution.

Keep the solution in dark amber-colored, glass-stoppered bottles.

One Cubic Centimeter of Tenth-normal Bromine Volumetric Solution is the Equivalent of:

	Gramme.
Bromine, Br.	0.007936
Phenol, C_6H_5OH	0.001556

Normal Hydrochloric Acid Volumetric Solution, U. S. (HCl, 36.18; 36.18 Gm. in 1000 Cc.).—Mix 130 Cc. of hydrochloric acid of specific gravity 1.158 with sufficient water to measure 1000 Cc. Of this liquid (which is still too concentrated) carefully measure, from a burette, 10 Cc. into a flask or porcelain dish, and after diluting with about double its volume of water add 2 drops of methyl-orange test-solution, then gradually add, from a burette, a freshly standardized normal potassium hydroxide volumetric solution, until the red tint of the solution changes, after vigorous shaking, to a permanent pale yellow. Note the number of Cc. of potassium hydroxide volumetric solution consumed, and then dilute the acid solution so that equal volumes of this and of the normal potassium hydroxide volumetric solution neutralize each other at 25° C. (77° F.).

Example.—Assuming that 10 Cc. of the acid solution first prepared required exactly 11 Cc. of normal potassium hydroxide volumetric solution, each 10 Cc. of the former must be diluted to 11 Cc., or the whole of the remaining acid solution in the same proportion at 25° C. (77° F.). Thus, if 950 Cc. should remain, 95 Cc. of water must be added.

After the liquid is thus diluted a new trial should be made in the manner above described, in which 50 Cc. of the acid solution should require for neutralization exactly 50 Cc. of normal potassium hydroxide volumetric solution. If necessary, a new adjustment should then be made to render the correspondence perfect at 25° C. (77° F.).

One Cubic Centimeter of Normal Hydrochloric Acid Volumetric Solution is the Equivalent of:

	Gramme.
Hydrochloric acid, absolute, HCl	0.03618

Note.—Normal hydrochloric acid is in every respect equivalent in neutralizing power to normal sulphuric acid (which see), and may be employed, except in special cases, for the same purposes. However, preference is generally given to the normal sulphuric acid volumetric solution.

Half-normal Hydrochloric Acid Volumetric Solution, U. S. (HCl, 36.18; 18.09 Gm. in 1000 Cc.).—Dilute 500 Cc. of normal hydrochloric acid volumetric solution with sufficient distilled water to measure exactly 1000 Cc. at 25° C. (77° F.).

One Cubic Centimeter of Half-normal Hydrochloric Acid Volumetric Solution is the Equivalent of:

	Gramme.
Hydrochloric acid, absolute, HCl	0.01809
Benzaldehyde, C_7H_6O	0.0526
Cinnamic aldehyde, C_9H_8O	0.0333
Citral, $C_{10}H_{16}O$	0.03802
Potassium acetate, $KC_2H_3O_2$ (after ignition)	0.04872
Potassium bicarbonate, $KHCO_3$	0.049705
Potassium bitartrate, $KHC_4H_4O_6$ (after ignition)	0.09339
Potassium carbonate, anhydrous, K_2CO_3	0.034318
Potassium citrate, cryst., $K_3C_6H_5O_7 + H_2O$ (after ignition)	0.05368
Potassium hydroxide, KOH	0.02787

Sodium hydroxide, NaOH	0.01988
Sodium salicylate, $NaC_7H_5O_3$ (after ignition)	0.079445

Tenth-normal Iodine Volumetric Solution, U. S. (I, 125.9; 12.59 Gm. in 1000 Cc.).—Tenth-normal iodine volumetric solution may be prepared according to either of the following methods:

I. Dissolve 12.59 Gm. of pure iodine (see below) in a solution of 18 Gm. of potassium iodide in 300 Cc. of water. Then add sufficient water to make the solution measure, at 25° C. (77° F.), exactly 1000 Cc. Unless freshly prepared, its strength should always be determined anew at the time it is used. Transfer the solution to glass-stoppered vials.

Preparation of Pure Iodine.—Heat powdered iodine in a porcelain dish placed over a bath of boiling water for twenty minutes, and stir it constantly with a glass rod, so that adhering moisture, cyanogen iodide, and most of the iodine bromide and iodine chloride, if present, may be vaporized. Then transfer the iodine to porcelain or other non-metallic mortar, and triturate it with about 5 per cent.

of its weight of dry potassium iodide, so as to decompose any remaining iodine bromide and iodine chloride. Then return the mass to the dish, cover it with a glass funnel, and heat the dish carefully on a sand-bath. Detach the sublimed, pure iodine, and, after pulverizing and drying for twenty-four hours over calcium chloride, keep it in well-stoppered bottles in a cool place.

II. Tenth-normal iodine volumetric solution may also be prepared as follows:

Dissolve about 14 Gm. of iodine in a solution of 18 Gm. of potassium iodide in about 300 Cc. of water, diluting finally to 1000 Cc. Of this solution (which is too concentrated), carefully measure from a burette 10 Cc. into a flask, then add gradually and cautiously, from a burette, tenth-normal sodium thiosulphate volumetric solution (shaking constantly) until the color of the solution is discharged. Note the number of Cc. of the sodium thiosulphate volumetric solution consumed, and then dilute the iodine solution so that any known volume of the latter will require for decolorization exactly the same volume of the tenth-normal sodium thiosulphate volumetric solution.

Example.—Assuming that 10 Cc. of the iodine solution required 10.8 Cc. of the tenth-normal sodium thiosulphate volumetric solution for decolorization, then each 10 Cc. of the former must be diluted to 10.8 Cc., or each 100 Cc. of the iodine solution to 108 Cc. at 25° C. (77° F.). After the solution is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the tenth-normal iodine volumetric solution should require exactly 50 Cc. of the tenth-normal sodium thiosulphate volumetric solution for complete decolorization. If necessary, a new adjustment should be made to render the correspondence perfect.

One Cubic Centimeter of Tenth-normal Iodine Volumetric Solution is the Equivalent of:

	Gramme.
Iodine, I	0.01259
Arsenic, As	0.00372
Arsenic trioxide (arsenous acid), As_2O_3	0.004911
Iron, Fe	0.002775
Potassium sulphite, crystallized, $K_2SO_3 + 2H_2O$	0.009648
Sodium bisulphite, $NaHSO_3$	0.005168
Sodium thiosulphate (hyposulphite), crystals, $Na_2S_2O_3 + 5H_2O$	0.024646
Sodium sulphite, crystallized, $Na_2SO_3 + 7H_2O$	0.012520
Sulphur dioxide, SO_2	0.003180
Antimony and potassium tartrate, crystallized, $2K(SbO)C_4H_4O_6 + H_2O$	0.016495

Tenth-normal Oxalic Acid Volumetric Solution, U. S. ($H_2C_2O_4 + 2H_2O$, 125.10; 6.255 Gm. in 1000 Cc.).—Dissolve 6.4 Gm. of pure oxalic acid in sufficient water to measure 1000 Cc.

Into a flask, accurately measure, from a burette, 10 Cc. of a *freshly standardized* tenth-normal potassium hydroxide volumetric solution, dilute with about 20 Cc. of water, add 3 to 5 drops of phenolphthalein test-solution, and heat to boiling. From a burette gradually add the oxalic acid solution (which is still too concentrated) until the red tint of the alkali solution fails to reappear after vigorous shaking and boiling. Note the number of Cc. of the oxalic acid solution consumed, and then dilute it so that equal volumes of this and of the tenth-normal potassium hydroxide volumetric solution neutralize each other at 25° C. (77° F.). It deteriorates on standing.

Example.—Assuming that the 10 Cc. of the tenth-normal potassium hydroxide volumetric solution required exactly 9.5 Cc. of the oxalic acid solution, then each 9.5 Cc. of the latter must be diluted to 10 Cc., or the whole of the remaining acid solution in the same proportion at 25° C. (77° F.). Thus, if 950 Cc. of the oxalic acid solution should remain, 50 Cc. of water must be added.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of tenth-normal potassium hydroxide volumetric solution should require for neutralization exactly 50 Cc. of the oxalic acid solution at 25° C. (77° F.). If necessary, a new adjustment should then be made to render the correspondence perfect.

NOTE.—Tenth-normal oxalic acid volumetric solution is in every respect equivalent in neutralizing power to any other tenth-normal acid volumetric solution with either litmus or phenolphthalein test-solution as indicator. Its most important use is in standardizing tenth-normal potassium permanganate volumetric solution.

One Cubic Centimeter of Tenth-normal Oxalic Acid Volumetric Solution is Equivalent of:

	Gramme.
Oxalic acid, crystallized, $H_2C_2O_4 + 2H_2O$	0.006255
Ammonia gas, NH_3	0.001693
Calcium hydroxide, $Ca(OH)_2$	0.003678
Lead subacetate, $Pb_2O(C_2H_3O_2)_2$	0.0135935
Manganese dioxide, precipitated, MnO_2	0.004318
Potassium hydroxide, KOH	0.005574
Potassium permanganate, $KMnO_4$	0.0031396
Sodium hydroxide, NaOH	0.003976

Tenth-normal Potassium Dichromate Volumetric Solution, U. S. ($K_2Cr_2O_7$, 292.28; 4.8713 Gm. in 1000 Cc.).—Dissolve 4.8713 Gm. of pure potassium dichromate, which has been pulverized and dried at 120° C. (248° F.) in sufficient water to measure, at 25° C. (77° F.), exactly 1000 Cc.

When used with phenolphthalein as indicator, to neutralize alkalies, the volumetric solution of potassium dichromate is tenth-normal when it contains 14.614 Gm. in 1000 Cc. It is then the exact

equivalent of any tenth-normal acid volumetric solution, each Cc. being equivalent to the amounts of alkalies quoted under such acids.

When used as an oxidizing agent to convert ferrous into ferric salts, or to liberate iodine from potassium iodide, the solution just mentioned (containing 14.614 Gm. in 1000 Cc.) has the effect of a three-tenth-normal volumetric solution, and a solution of one-third of this strength, containing 4.8713 Gm. in 1000 Cc., has the value of a tenth-normal solution, and is the equivalent of an equal volume of tenth-normal potassium permanganate volumetric solution, or, in the case of iodine liberated from potassium iodide, it is the equivalent of an equal volume of tenth-normal sodium thiosulphate volumetric solution. For titrating iron in *ferrous* compounds, it is used in the following manner: Introduce the aqueous solution of the ferrous salt into a flask and, if it is not already acid, render it so with sulphuric acid. Now add, gradually, tenth-normal potassium dichromate volumetric solution from a burette, with agitation, until a drop taken out upon a white surface no longer becomes blue when mixed with a drop of freshly prepared potassium ferricyanide test-solution.

Tenth-normal potassium dichromate volumetric solution may also be used, in conjunction with potassium iodide (from which it liberates iodine) and sulphuric acid, for adjusting the titer of sodium thiosulphate volumetric solution and thus that of the iodine volumetric solution.

One Cubic Centimeter of Tenth-normal Potassium Dichromate Volumetric Solution is the Equivalent of:

	Gramme.
Potassium dichromate, $K_2Cr_2O_7$	0.0048713
Iron, Fe, in ferrous compounds	0.00555
Ferrous carbonate, $FeCO_3$	0.011505
Ferrous sulphate, anhydrous, $FeSO_4$	0.015085
Ferrous sulphate, crystallized, $FeSO_4 + 7H_2O$	0.027601
Ferrous sulphate, dried, $2FeSO_4 + 3H_2O$	0.017767
Sodium thiosulphate, $Na_2S_2O_3 + 5H_2O$	0.024646

Normal Potassium Hydroxide Volumetric Solution, U. S. (KOH, 55.74; 55.74 Gm. in 1000 Cc.).—Dissolve 75 Gm. of potassium hydroxide in sufficient water to measure about 1050 Cc., and fill a burette with a portion of this liquid.

Into a flask of the capacity of about 300 Cc. introduce 9.339 Gm. of potassium bitartrate, which has been purified and dried as directed under Reagents, and 160 Cc. of distilled water. Boil the liquid until solution has taken place, add from 3 to 5 drops of phenolphthalein test-solution, followed by the cautious addition, from a burette, of the potassium hydroxide solution, frequently agitating the flask, boiling, and, toward the end of the operation, reducing the flow to drops until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of Cc. of the potassium hydroxide solution consumed, and then dilute the remainder of the solution so that exactly 50 Cc. of the diluted liquid at 25° C. (77° F.) shall be required to neutralize the 9.339 Gm. of potassium bitartrate used.

Example.—Assuming that 40 Cc. of the stronger solution of potassium hydroxide first prepared had been consumed in the trial, then each 40 Cc. must be diluted to 50 Cc., or the whole of the remaining solution in the same proportion at 25° C. (77° F.). Thus, if 1000 Cc. should be still remaining, this must be diluted with water to 1250 Cc.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the diluted solution should exactly neutralize 9.339 Gm. of potassium bitartrate at 25° C. (77° F.). If necessary, a new adjustment should then be made to render the correspondence perfect.

NOTE.—Solutions of caustic alkalies absorb carbon dioxide from the atmosphere, and thereby change their titer when used with litmus test-solution, or phenolphthalein test-solution, as indicator (methyl-orange test-solution is not affected by the presence of carbonic acid). Hence the volumetric solutions should be preserved in bottles provided with well-fitting rubber stoppers, or, better still, these should be provided with tubes filled with soda-lime (a mixture of caustic soda and lime); the tubes pass through a perforation in the rubber stoppers, and thus absorb the carbon dioxide and prevent its access to the solution. If the solution is kept in a burette for any length of time, the same provision with a soda-lime tube should be observed.

In place of potassium hydroxide volumetric solution, sodium hydroxide volumetric solution may be used, in the same manner and in the same quantity. Potassium hydroxide volumetric solution, however, is preferable, since it foams less and attacks glass more slowly.

One Cubic Centimeter of Normal Potassium Hydroxide Volumetric Solution is the Equivalent of:

	Gramme.		Gramme.
Potassium hydroxide, KOH	0.05574	Lactic acid, absolute, $HC_3H_5O_3$	0.08937
Acetic acid, absolute, $HC_2H_3O_2$	0.05958	Nitric acid, absolute, HNO_3	0.06257

Hydrochloric acid, absolute, HCl	0.03618	Trichloracetic acid, CCl_3COOH	0.16212
Hypophosphorous acid, HPH_2O_2	0.06553		

Tenth-normal Potassium Hydroxide Volumetric Solution, U. S. (KOH, 55.74; 5.574 Gm. in 1000 Cc.)—Dilute 100 Cc. of freshly standardized normal potassium hydroxide volumetric solution with sufficient distilled water to measure, at 25° C. (77° F.), exactly 1000 Cc.

This solution may also be prepared and standardized directly with potassium bitartrate, as directed under normal potassium hydroxide volumetric solution, employing for this purpose 0.9339 Gm. of the former and a solution of about 7.5 Gm. of potassium hydroxide in 1000 Cc. of distilled water. 50 Cc. of the prepared tenth-normal solution of 25° C. (77° F.) should exactly neutralize 0.9339 Gm. of potassium bitartrate.

NOTE.—The same precautions should be taken for protecting this solution from carbon dioxide of the air as are directed under normal potassium hydroxide volumetric solution.

One Cubic Centimeter of Tenth-normal Potassium Hydroxide Volumetric Solution is the Equivalent of:

	Gramme.
Potassium hydroxide, KOH	0.005574
Sulphuric acid, absolute, H_2SO_4	0.0048675

Fiftieth-normal Potassium Hydroxide Volumetric Solution, U.S. (KOH, 55.74; 1.1148 Gm. in 1000 Cc.).—Dilute 20 Cc. of a freshly standardized normal or 200 Cc. of tenth-normal potassium hydroxide volumetric solution with sufficient distilled water to measure, at 25° C. (77° F.), exactly 1000 Cc. This standard solution is employed in conjunction with the tenth-normal sulphuric acid volumetric solution in the titration of alkaloids, with hematoxylin, cochineal, or iodeosin test-solution as indicators.

NOTE.—The same precautions should be taken for protecting this solution from carbon dioxide of the air as are directed under normal potassium hydroxide volumetric solution. It should be renewed at frequent intervals.

One Cubic Centimeter of Fiftieth-normal Potassium Hydroxide Volumetric Solution is the Equivalent of:

	Gramme.		Gramme.
Potassium hydroxide, KOH	0.0011148	Coniine, $C_8H_{17}N$	0.002524

Hundredth-normal Potassium Hydroxide Volumetric Solution, U. S. (KOH, 55.74; 0.5574 Gm. in 1000 Cc.).—Dilute 10 Cc. of normal or 100 Cc. of tenth-normal potassium hydroxide volumetric solution with sufficient water to measure, at 25° C. (77° F.), exactly 1000 Cc. The solution must be frequently renewed.

One Cubic Centimeter of Hundredth-normal Potassium Hydroxide Volumetric Solution is the Equivalent of:

	Gramme.
Potassium hydroxide, KOH	0.0005574
Sulphuric acid, absolute, H_2SO_4	0.00048675

Half-normal Alcoholic Potassium Hydroxide Volumetric Solution, U. S. (KOH, 55.74; 27.87 Gm. in 1000 Cc.).—Dissolve about 40 Gm. of potassium hydroxide, which has been broken into small pieces in about 20 Cc. of water, and add sufficient alcohol, to measure 1000 Cc. After setting aside in a well-stoppered bottle for 1 day, the clear supernatant solution should be quickly decanted into a bottle provided with a well-fitted rubber stopper.

Into a flask of the capacity of about 300 Cc., introduce 1.8678 Gm. of potassium bitartrate, which has been purified and dried, as directed under Reagents, and about 100 Cc. of distilled water. Heat the solution to the boiling point, add 5 drops of phenolphthalein test-solution, followed by the cautious addition, from a burette, of the potassium hydroxide solution, frequently agitating the flask, boiling, and, toward the end of the operation, reducing the flow to drops until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of Cc. of the alcoholic potassium hydroxide solution consumed, and then dilute the remainder of the solution with alcohol so that exactly 20 Cc. of the diluted liquid shall be required to neutralize the 1.8678 Gm. of potassium bitartrate used.

Example.—Assuming that 12.5 Cc. of the stronger alcoholic solution of potassium hydroxide first prepared had been consumed in the trial, then each 12.5 Cc. must be diluted with alcohol to 20 Cc., or the whole of the remaining solution in the same proportion at 25° C. (77° F.). Thus, if 980 Cc. should remain, this must be diluted with alcohol to measure 1568 Cc.

Half-normal alcoholic potassium hydroxide volumetric solution may also be prepared as follows: Of the above-described concentrated alcoholic potassium hydroxide solution, carefully measure, from

a burette, 20 Cc. into a flask, and, after diluting with about 50 Cc. of water, add about 5 drops of phenolphthalein test-solution, heat to a boiling temperature, and add, from a burette, half-normal hydrochloric acid volumetric solution, frequently agitating the flask, and, toward the end of the operation, reducing the flow to drops until the red color is just discharged. Note the number of Cc. of the half-normal hydrochloric acid volumetric solution consumed, then dilute the remainder of the solution with alcohol, so that equal volumes of this and of the half-normal hydrochloric acid volumetric solution neutralize each other at 25° C. (77° F.).

Should half-normal hydrochloric acid volumetric solution not be available, standardization can be carried out in the same manner with normal hydrochloric acid volumetric solution, 2 volumes of the alcoholic potassium hydroxide being made to correspond with 1 volume of the standard acid.

NOTE.—This solution should be kept in bottles provided with a well-fitted rubber stopper and protected from the light. Owing to the readiness with which this standard solution loses its titer, blank tests should be performed whenever it is employed in titrations.

One Cubic Centimeter of Half-normal Alcoholic Potassium Hydroxide Volumetric Solution is the Equivalent of:

	Gramme.
Potassium hydroxide, KOH	0.02787
Borneol, $C_{10}H_{18}O$	0.07649
Bornyl acetate, $C_{10}H_{17}O.C_2H_3O$	0.09734
Menthol, $C_{10}H_{20}O$	0.07749
Menthyl acetate, $C_{10}H_{19}O.C_2H_3O$	0.09834
Santalol, $C_{15}H_{26}O$	0.11026

Tenth-normal Potassium Permanganate Volumetric Solution, U. S. ($2KMnO_4$, 313.96; 3.1396 Gm.[1] in 1000 Cc.).—Introduce about 3.3 Gm. of pure, crystallized potassium permanganate into a flask, add 1000 Cc. of distilled water, and boil for about 5 minutes. Close the flask with a plug of absorbent cotton, and set aside for at least 2 days, so that suspended matter may deposit. After the lapse of this time pour off the clear portion of the solution into a glass-stoppered bottle.

The water to be employed for diluting this solution (which is still too concentrated) should be prepared as directed under DISTILLED WATER, adding, however, about 1 Gm. of potassium permanganate to the water in the retort before beginning the distillation.

I. Introduce into a flask 10 Cc. of an accurately standardized tenth-normal oxalic acid volumetric solution, add 1 Cc. of pure, concentrated sulphuric acid, and before this mixture cools gradually add, from a burette provided with a glass stop-cock, small quantities of the permanganate solution to be standardized, shaking the flask after each addition and reducing the flow to drops toward the end of the operation. When the last drop of the permanganate solution added is no longer decolorized but imparts a pinkish tint to the liquid, which remains permanent for one-half minute, note the number of Cc. consumed, and then dilute the trial permanganate solution with the specially prepared distilled water so that it will correspond, volume for volume, at 25° C. (77° F.), with the tenth-normal oxalic acid volumetric solution (note example under II.).

II. Tenth-normal potassium permanganate volumetric solution may also be standardized as follows:

To a solution of about 1 Gm. of potassium iodide, in 10 Cc. of diluted sulphuric acid, contained in a flask, add, from a burette provided with a glass stop-cock, 20 Cc. of the potassium permanganate solution to be standardized; then dilute the mixture at once with about 200 Cc. of distilled water. An accurately standardized tenth-normal sodium thiosulphate volumetric solution is then slowly added from a burette, while the mixture is vigorously shaken, until the color is discharged. Note the number of Cc. of the latter consumed, then dilute the permanganate solution so that equal volumes of the two solutions correspond to each other under the same conditions at 25° C. (77° F.).

Example.—Assuming that 25 Cc. of the tenth-normal sodium thiosulphate volumetric solution were required to decolorize the liberated iodine of the mixture, then each 20 Cc. of the potassium permanganate solution must be diluted with the specially prepared distilled water to 25 Cc., or the whole of the remaining solution in the same proportion. Thus, if 920 Cc. remain, it should be diluted to measure 1150 Cc. at 25° C. (77° F.).

After the potassium permanganate solution is thus diluted, a new trial should be made in the manner above described, in which 20 Cc. of this solution should require exactly 20 Cc. of the tenth-normal sodium thiosulphate volumetric solution to decolorize the mixture. If necessary a new adjustment should be made to render the correspondence perfect.

NOTE.—When potassium permanganate volumetric solution is to be prepared for immediate use, this may be done as follows: Dissolve about 3.3 Gm. of pure, crystallized potassium permanganate in 1000 Cc. of recently boiled and cooled pure water. This is then standardized by either of the above methods and diluted accordingly with recently boiled and cooled pure water. Potassium permanganate volumetric solution made by this method without the preliminary boiling and standing deteriorates readily, hence it should be verified each time it is used.

Potassium permanganate volumetric solution should be kept in well-closed glass-stoppered bottles, and only burettes provided with glass stop-cocks should be employed in titrating with it. Even when properly prepared and preserved, this solution should be restandardized frequently.

[1] The exact quantity is never weighed, but the solution is adjusted directly by oxalic acid or indirectly with sodium thiosulphate.

One Cubic Centimeter of Tenth-normal Potassium Permanganate Volumetric Solution is the Equivalent of:

	Gramme.		Gramme.
Potassium permanganate, $KMnO_4$	0.0031396	Ferrous sulphate, crystals, $FeSO_4 + 7H_2O$	0.027601
Calcium oxide, CaO (as oxalate)	0.002784	Ferrous sulphate, dried, $2FeSO_4 + 3H_2O$	0.017767

Ferrous carbonate, $FeCO_3$	0.011505	Oxalic acid, crystallized, $H_2C_2O_4 + 2H_2O$	0.006255
Ferrous oxide, FeO	0.007138	Oxygen, O	0.000794
Ferrous sulphate, anhydrous, $FeSO_4$	0.015085	Sodium nitrite, $NaNO_2$	0.0034285

Tenth-normal Potassium Sulphocyanate Volumetric Solution, U. S. [*Volhard's Solution*].—(KSCN, 96.53; 9.653 Gm. in 1000 Cc.).—Dissolve 10 Gm. of crystals of pure potassium sulphocyanate in 1000 Cc. of water.

This solution is too concentrated, and has to be adjusted so as to correspond in strength exactly with tenth-normal silver nitrate volumetric solution. For this purpose, introduce into a flask 10 Cc. of tenth-normal silver nitrate volumetric solution, 3 Cc. of ferric ammonium sulphate test-solution, and 3 Cc. of nitric acid (free from nitrous compounds), and dilute the liquid with about 100 Cc. of distilled water. To this mixture add, from a burette, in small portions at a time, the sulphocyanate solution. At first a white precipitate of silver sulphocyanate appears, then every drop falling from the burette is surrounded by a deep brownish-red color produced by ferric sulphocyanate, which disappears on vigorous shaking of the flask as long as any of the silver nitrate remains unchanged. When all the silver has been converted into sulphocyanate, a single additional drop of the potassium sulphocyanate solution produces a brownish-red color which no longer disappears on shaking, but communicates a perceptible pale reddish-brown tint to the contents of the flask. Note the number of Cc. of the potassium sulphocyanate solution used, and dilute the whole of the remaining solution so that equal volumes of this and of the tenth-normal silver nitrate volumetric solution, at 25° C. (77° F.), will be required to produce the permanent reddish-brown tint. (The same depth of pale reddish-brown tint to which the volumetric solution is adjusted must be attained when the solution is used for volumetric assays.)

After the dilution, a new trial should be made, in which 50 Cc. of tenth-normal silver nitrate volumetric solution, 5 Cc. of ferric ammonium sulphate test-solution, 5 Cc. of nitric acid, and 200 Cc. of water are used, and there should be required exactly 50 Cc. of the potassium sulphocyanate solution, at 25° C. (77° F.), to produce the same depth of a permanent pale reddish-brown tint.

If necessary, a new adjustment should be made to render the correspondence perfect.

One Cubic Centimeter of Tenth-normal Potassium Sulphocyanate Volumetric Solution is the Equivalent of:

	Gramme.
Potassium sulphocyanate, KSCN	0.009653
Silver, Ag	0.010712
Silver nitrate, $AgNO_3$	0.016869

Tenth-normal Silver Nitrate Volumetric Solution, U. S. ($AgNO_3$, 168.69; 16.869 Gm. in 1000 Cc.).—Dissolve 16.869 Gm. of silver nitrate, which, previous to weighing, has been pulverized and dried in a covered porcelain crucible in an air-bath at 130° C. (266° F.) for 1 hour, in sufficient water to measure, at 25° C. (77° F.), exactly 1000 Cc.

Keep the solution in dark amber-colored, glass-stoppered vials, carefully protected from dust and sunlight.

NOTE.—Titration by tenth-normal silver nitrate volumetric solution may be conducted in various ways, adapted to the special preparation to be tested:

a. The titration of soluble chlorides and bromides.—To the solution of an accurately weighed quantity of the salt, contained in either a porcelain dish or a flask placed on a white surface, sufficient potassium chromate test-solution is added to impart a yellow tint, then the tenth-normal silver nitrate volumetric solution is slowly added from a burette, stirring or agitating constantly until the mixture acquires a permanent red tint, due to the formation of red silver chromate. This method is only suitable for neutral solutions.

b. The titration of free hydrobromic, hydrochloric, and hydriodic acids or their salts in acid solution, known as the Volhard or Thiocyanate (Sulphocyanate) method of residual titration.—An accurately measured excess of tenth normal silver nitrate volumetric solution is added to the solution of the halogen acid or its salt, and then acidified with pure nitric acid, and the indicator (ferric ammonium sulphate test-solution) added; then the uncombined excess of the silver nitrate volumetric solution is determined by titrating back with tenth-normal potassium sulphocyanate volumetric solution, the end-reaction being the formation of a permanent pale reddish-brown tint (due to ferric sulphocyanate). The volume of the silver nitrate volumetric solution originally added, less that of the potassium sulphocyanate volumetric solution consumed, will give the number of Cc. of the former which were required for the precipitation of the halogen. The quantity of nitric acid added should be sufficient to remove the yellow color produced by the addition of the indicator.

c. Titration till the first appearance of a permanent precipitate.—This method is applicable in the estimation of the alkali cyanides and hydrocyanic acid. When the solution is used by this method it is fifth-normal instead of tenth-normal solution.

One Cubic Centimeter of Tenth-normal Silver Nitrate Volumetric Solution is the Equivalent of:

Tenth-normal Sodium Chloride Volumetric Solution, U. S. (NaCl, 58.06; 5.806 Gm. in 1000 Cc.).—Dissolve 5.806 Gm. of pure sodium chloride (see below) in sufficient water to measure, at 25° C. (77° F.), exactly 1000 Cc.

Pure sodium chloride may be prepared by passing a current of dry hydrochloric acid gas into a saturated aqueous solution of the purest commercial sodium chloride, collecting the crystalline precipitate on a filter, washing with a little pure concentrated hydrochloric acid, draining, pulverizing, and igniting it gently in a crucible heated to low redness, to expel all traces of free acid. Care should be taken to avoid fusion.

One Cubic Centimeter of Tenth-normal Sodium Chloride Volumetric Solution is the Equivalent of:

	Gramme.
Sodium chloride, NaCl	0.005806
Silver, Ag	0.010712
Silver nitrate, $AgNO_3$	0.016869
Silver oxide, Ag_2O	0.011506

Double-normal Sodium Hydroxide Volumetric Solution, U. S. (NaOH, 39.76; 79.52 Gm. in 1000 Cc.).—Dissolve 90 Gm. of sodium hydroxide in sufficient water to measure about 1000 Cc.

For the standardization of this approximate solution of sodium hydroxide proceed as directed under normal potassium hydroxide volumetric solution; 25 Cc. of the volumetric solution, at 25° C. (77° F.), should exactly neutralize 9.339 Gm. of pure potassium bitartrate (see Reagents).

NOTE.—The same precautions should be taken for protecting this solution from the carbon dioxide of the air as are prescribed for normal potassium hydroxide volumetric solution.

Normal Sodium Hydroxide Volumetric Solution, U. S. (NaOH, 39.76; 39.76 Gm. in 1000 Cc.).—Dissolve 54 Gm. of sodium hydroxide in sufficient water to measure about 1050 Cc., and fill a burette with a portion of this liquid.

For the standardization of this approximate solution of sodium hydroxide, proceed as directed under normal potassium hydroxide volumetric solution (which see); 50 Cc. of the volumetric solution, at 25° C. (77° F.), must exactly neutralize 9.339 Gm. of pure potassium bitartrate.

NOTE.—The same precautions should be taken for protecting this solution from the carbon dioxide of the air as are prescribed for normal potassium hydroxide volumetric solution.

This solution may be employed in place of the normal potassium hydroxide volumetric solution volume for volume.

One Cubic Centimeter of Normal Sodium Hydroxide Volumetric Solution is the Equivalent of:

	Gramme.
Sodium hydroxide, NaOH	0.03976
Boric acid, H_3BO_3	0.06154
Formaldehyde, CH_2O	0.02979
Trichloracetic acid, $HC_2Cl_3O_2$	0.16212

Tenth-normal Sodium Thiosulphate Volumetric Solution, U. S. ($Na_2S_2O_3 + 5H_2O$, 246.46; 24.646 Gm. in 1000 Cc.).—Dissolve 30 Gm. of sodium thiosulphate in sufficient distilled water to measure 1000 Cc. This trial solution, which is too concentrated, is standardized as follows:

To a solution of about 1 Gm. of potassium iodide in 10 Cc. of diluted sulphuric acid contained in a flask of about 500 Cc. capacity, add slowly, from a burette, 20 Cc. of tenth-normal potassium dichromate volumetric solution, shaking after each addition. Place a watch-glass on the mouth of the flask and allow it to stand for 5 minutes, then dilute the solution with about 250 Cc. of distilled water, add

some starch test-solution, and then, from a burette, the trial solution of sodium thiosulphate, in small portions at a time, shaking after each addition, and, toward the end of the operation, reducing the flow to drops, until the blue color of the mixture changes to a light green; note the number of Cc. of the trial sodium thiosulphate solution consumed. Then dilute the sodium thiosulphate solution so that equal volumes of it and the tenth-normal potassium dichromate volumetric solution will exactly correspond to each other under the above conditions, at 25° C. (77° F.).

Example.—Assuming that 16 Cc. of the trial sodium thiosulphate solution were required to decolorize the liberated iodine of the mixture, then each 16 Cc. of this solution must be diluted to 20 Cc. so that it will correspond in volume to the tenth-normal potassium dichromate volumetric solution added, or the whole of the remaining solution in the same proportion at 25° C. (77° F.). Thus, if 984 Cc. of the sodium thiosulphate solution are remaining, this should be diluted to measure 1230 Cc. After the sodium thiosulphate solution is thus diluted, a new trial should be made in the manner above described, in which exactly 20 Cc. of this solution should be required to decolorize the iodine liberated by 20 Cc. of the tenth-normal dichromate volumetric solution. If necessary, a new adjustment should be made to render the correspondence perfect.

Keep the solution in glass-stoppered bottles, carefully protected from dust.

NOTE.—When this solution is to be used fill a burette with it, place the liquid to be tested either for the free iodine it already contains, or for that which it liberates from an excess of potassium iodide added to it, in a flask, and gradually add small portions of the solution from the burette, shaking after each addition, and, toward the end of the operation, reducing the flow to drops, until the color is discharged.

One Cubic Centimeter of Tenth-normal Sodium Thiosulphate Volumetric Solution is the Equivalent of:

	Gramme.
Sodium thiosulphate (hyposulphite), $Na_2S_2O_3 + 5H_2O$	0.024646
Bromine, Br.	0.007936
Chlorine, Cl	0.003518
Chromium trioxide, CrO_3	0.003311
Iodine, I	0.01259
Iron, Fe, in ferric salts	0.00555
Potassium bromate, $KBrO_3$	0.002764

Normal Sulphuric Acid Volumetric Solution, U. S. (H_2SO_4, 97.35; 48.675 Gm. in 1000 Cc.).—Carefully mix 30 Cc. of pure, concentrated sulphuric acid (of specific gravity 1.826 at 25° C. (77° F.) with sufficient water to measure about 1050 Cc., and allow the liquid to cool to 25° C. (77° F.). Measure from a burette 10 Cc. of this liquid (which is yet too concentrated) into a flask, add 2 drops of methyl-orange test-solution, and afterwards, from a burette, a freshly standardized normal potassium hydroxide volumetric solution, shaking after each addition, and, toward the end of the operation, reducing the flow to drops, until the red tint of the solution changes to a permanent pale yellow after thorough shaking. Note the number of Cc. of normal potassium hydroxide volumetric solution consumed. Then dilute the sulphuric acid solution so that equal volumes of this and of normal potassium hydroxide volumetric solution, at 25° C. (77° F.), exactly neutralize each other.

Example.—Assuming that 10 Cc. of the acid solution first prepared had required exactly 11.2 Cc. of normal potassium hydroxide volumetric solution, each 10 Cc. of the former must be diluted to 11.2 Cc., or each 1000 Cc. to 1120 Cc.

After the liquid is thus diluted a new trial should be made in the manner above described, in which 50 Cc. of the acid solution should require for neutralization exactly 50 Cc. of normal potassium hydroxide volumetric solution, at 25° C. (77° F.). If necessary, a new adjustment should be made to render the correspondence perfect.

One Cubic Centimeter of Normal Sulphuric Acid Volumetric Solution is the Equivalent of:

Half-normal Sulphuric Acid Volumetric Solution, U. S. (H_2SO_4, 97.35; 24.3375 Gm. in 1000 Cc.).—Dilute 500 Cc. of normal sulphuric acid with sufficient water to measure 1000 Cc. at 25° C. (77° F.).

This standard solution is chiefly employed in the titration of the organic salts of sodium and potassium in conjunction with methyl-orange as indicator. For this purpose a special experiment should be made in which an accurately measured volume of 10 Cc. of normal potassium hydroxide volumetric solution should, after adding 2 drops of methyl-orange test-solution, require exactly 20 Cc. of the half-normal sulphuric acid volumetric solution for neutralization.

If necessary, an adjustment should be made to render the correspondence perfect.

One Cubic Centimeter of Half-normal Sulphuric Acid Volumetric Solution is the Equivalent of:

	Gramme.		Gramme.
Sulphuric acid, absolute, H_2SO_4	0.0243375	Sodium acetate, $NaC_2H_3O_2 + 3H_2O$ (after ignition)	0.06755

Potassium and sodium tartrate, $KNaC_4H_4O_6 + 4H_2O$ (after ignition)	0.070045		

Tenth-normal Sulphuric Acid Volumetric Solution, U. S. (H_2SO_4, 97.35; 4.8675 Gm. in 1000 Cc.)—Dilute 100 Cc. of normal sulphuric acid with sufficient water to measure 1000 Cc. at 25° C. (77° F.).

This standard solution is employed in conjunction with the fiftieth-normal potassium hydroxide volumetric solution in the titration of alkaloids, with hematoxylin, cochineal, or iodeosin test solution as an indicator. For this purpose a special experiment should be made, in which an accurately measured volume of 10 Cc. of the tenth-normal sulphuric acid, after adding 1 Cc. of hematoxylin test-solution (or a sufficient quantity of the indicator to be employed), should require 50 Cc. of the fiftieth-normal potassium hydroxide volumetric solution for complete neutralization, at 25° C. (77° F.). If necessary, an adjustment should be made to render the correspondence perfect.

One Cubic Centimeter of Tenth-normal Sulphuric Acid Volumetric Solution is the Equivalent of:

Fiftieth-normal Sulphuric Acid Volumetric Solution, U. S. (H_2SO_4, 97.35; 0.9735 Gm. in 1000 Cc.).—Dilute 20 Cc. of normal sulphuric acid volumetric solution, or 200 Cc. of tenth-normal sulphuric acid volumetric solution, with sufficient distilled water to measure, at 25° C. (77° F.), 1000 Cc. This standard solution may be employed in the titration of alkaloids, with hematoxylin, cochineal, or iodeosin test-solution as an indicator.

One Cubic Centimeter of Fiftieth-normal Sulphuric Acid Volumetric Solution is the Equivalent of:

GASOMETRIC ESTIMATIONS.

In certain cases the Pharmacopœia directs the strength of a product or chemical substance to be determined by the volume of gas (nitrogen dioxide) given off during a definite reaction. This volume is to be determined by the nitrometer in the following manner:

Arrange a nitrometer consisting of a measuring tube (graduated for at least 50 Cc.) connected by stout rubber tubing, with an open equilibrium tube (both tubes, preferably, provided with a globular expansion near the lower end), in such a manner, by suitable clamps attached to a stand, that either tube may be readily and quickly clamped at a higher or lower level. The stop-cock of the measuring tube having been opened, and the open equilibrium tube having been raised to a higher level, pour into the latter a saturated aqueous solution of sodium chloride, until the measuring tube, including the bore of the stop-cock, is completely filled. Then close the latter and fix the equilibrium tube at a low level. Having ascertained that the stop-cock is closed air-tight, and having, if necessary, wiped out the graduated funnel tube of the nitrometer, introduce into it the prescribed quantity of the liquid to be tested, and allow this to flow slowly into the measuring tube, being careful not to admit any air. Follow it by the prescribed quantities of the several reagents (potassium iodide test-solution, and normal sulphuric acid volumetric solution). When the reaction, which takes place at once, moderates, remove the measuring tube from its clamp, and, being careful to hold it constantly so that the liquid contained in it stands at a higher level than in the equilibrium tube, shake its contents, without permitting any gas to pass into the open tube. When the reaction has completely ceased, restore the tube to its fastening, and allow the apparatus and contents to acquire the ordinary temperature of the room, which is assumed to be at or about 25° C. (77° F.). Then adjust the two tubes so that the liquid columns are at exactly the same level, and read off the volume of gas in the measuring tube. Multiply this figure by the weight of the substance, which is the equivalent of 1 Cc. of nitrogen dioxide (see next page). The result will be the weight of the pure substance (nitrite) contained in the amount taken for the assay.

For pharmacopœial purposes the determination will be sufficiently exact if the evolved gas be measured at or near 25° C. (77° F.).

Since temperature and barometric pressure materially affect the volume of the gas, the following correction factors must be used to obtain reasonably exact results when the temperature and pressure are not nearly normal. The barometer correction is important at any locality more than 250 meters above sea-level.

Factors for Temperature Corrections.

(Normal Temperature, 25° C.)

Temperature.	Factor.	Temperature.	Factor.	Temperature.	Factor.
15° C.	1.035	22° C.	1.010	29° C.	0.987
16° C.	1.031	23° C.	1.007	30° C.	0.983
17° C.	1.028	24° C.	1.003	31° C.	0.980
18° C.	1.024	25° C.	1.000	32° C.	0.977
19° C.	1.021	26° C.	0.997	33° C.	0.974
20° C.	1.017	27° C.	0.993	34° C.	0.971
21° C.	1.014	28° C.	0.990	35° C.	0.968

Example.—Assuming that the volume of gas read off was 44.5 Cc. at 32° C. (89° F.), and it is desired to ascertain the corresponding volume at 25° C. (77° F.), barometric pressure not being taken into consideration, then the 44.5 Cc. must be reduced in the proportion of 1 to 0.977 (see temperature correction factors above), or 44.5 must be multiplied by 0.977. The result will be 43.48 (43.4765) Cc. as the equivalent volume of gas at 25° C. (77° F.).

Factors for Correction for Barometric Pressure.

(Normal Barometer, 760 Mm.)

Barometer Reading.		Factor.	Barometer Reading.		Factor.
Mm.	Inches.		Mm.	Inches.	
790	31.10	1.039	660	25.98	0.868
780	30.71	1.026	650	25.59	0.855
770	30.31	1.013	640	25.20	0.842
760	29.92	1.000	630	24.80	0.829
750	29.53	0.987	620	24.41	0.816
740	29.13	0.974	610	24.02	0.803
730	28.74	0.961	600	23.62	0.789
720	28.35	0.947	590	23.23	0.776
710	27.95	0.934	580	22.83	0.763
700	27.56	0.921	570	22.44	0.750
690	27.17	0.907	560	22.05	0.737
680	26.77	0.895	550	21.65	0.724
670	26.38	0.882			

Example.—Assuming that the volume of gas read off was 43.48 (43.4765) Cc. at 590 Mm. barometric pressure, and it is desired to ascertain the corresponding volume at normal barometric pressure (760 Mm.), temperature not being taken into consideration, then the 43.48 Cc. must be reduced in the proportion of 1 to 0.776 (see barometric correction factors above), or 43.48 must be multiplied by 0.776. The result will be 33.74 Cc. as the equivalent volume of gas at normal barometric pressure.

Estimation of Nitrogen Dioxide (NO, 29.81) 1 liter at 0° C. and 760 Mm., 1.3396 Gm.; at 25° C. and 760 Mm., 1.2272 Gm.

One Cubic Centimeter Nitrogen of Dioxide is the equivalent of:

		At 0° C. and 760 Mm.	At 25° C. and 760 Mm.

ALKALOIDAL ASSAY BY IMMISCIBLE SOLVENTS.

Nearly all alkaloids are practically insoluble in water, but they are soluble in alcohol, chloroform, ether, amyl alcohol, benzene, petroleum benzin, or mixtures of several of these. The salts of these alkaloids, however, are soluble in water, but practically insoluble in the above-mentioned solvents. The process of assay by immiscible solvents, which is generally known as the "shaking out" process, is based on this property of alkaloids, and it is carried out by treating liquid extracts that have been freed from alcohol, with an immiscible solvent in the presence of an excess of alkali. This liberates the alkaloid, and, on becoming free, if not so previously, it is dissolved by the immiscible solvent. This solution is then separated, transferred to another container, and shaken with an excess of acid largely diluted with water. The acid combining with the free alkaloid forms a salt, which now leaves the immiscible solvent and is found in the aqueous solution. This process is sometimes repeated, in case the alkaloidal solution is still colored. The apparatus used in this operation of shaking out is termed a "separator," and consists of an oval or pear-shaped glass vessel, with an opening at the top supplied with a well-ground glass stopper, and an outlet tube at the bottom, provided with an accurately fitting glass stop-cock. The solvents directed to be used in this Pharmacopœia are alcohol, chloroform, ether, and various mixtures of both, containing at least 75 parts of ether in 100 parts of solvent by volume. In the case of chloroform, the solvent will collect at the bottom of the separator, and can be drawn off, but the ethereal or ether-chloroform mixture will form the upper portion of the liquid in the separator, and the aqueous layer must first be drawn off into a suitable vessel, and the ethereal layer then transferred to another vessel. It is not necessary or desirable to shake the mixture of immiscible solvent and water violently, for a rotation of the separator or a gentle shaking for about a minute will answer all purposes. At times, an emulsion of the water and the solvent is formed, especially if the shaking is too violent, and in order to separate this it is advisable to proceed as follows: If the solvent is heavier than the water, add more of the former, a little water, and a slight amount of alcohol; if the solvent is lighter than the water, add sufficient saturated sodium chloride solution or crystals of sodium chloride. A safe procedure to avoid the forming of emulsions is to invert the separator several times, and then to at once begin rotating to keep the solvents well mixed. To insure a complete extraction of the alkaloid, it is desirable to treat the liquid three times with the immiscible solvent, and this is to be followed by a rinsing of the empty separator with repeated small portions of the same solvent. The separator should not be filled to more than two-thirds of its capacity at any time, and if its contents should become heated by the neutralization of acid by alkali, or *vice versa*, it should be cooled to the temperature of the room, before opening the stopper, by immersing it in running water. The final operation must always be the collection of the free alkaloid by the use of a portion of the immiscible solvent, drawing this off into a beaker, rinsing with small portions of the solvent to prevent possible loss. The beaker is then placed on a water-bath and gently heated, to remove the solvent by evaporation, leaving the alkaloids in the beaker in the dry form, and usually in the condition of a resinous or varnish-like mass. It is then either weighed as such or dissolved in volumetric acid solution, delivered in measured quantity from a burette, and the excess of the acid titrated with volumetric alkali solution with the use of an indicator. Should the final residual alkaloids still be slightly colored, it is preferable to employ iodeosin as the indicator, as the alkaloidal solution contains ether and the ethereal layer retains in solution coloring matter or impurity which may be present. If the alkaloids are not colored, hematoxylin or cochineal may safely be used.

The quantity of alkaloid is found by multiplying the number of cubic centimeters of volumetric acid consumed by a constant factor, depending upon the molecular weight of the individual alkaloid. These factors will be found in this Appendix, on page 1687, under Tenth-normal Sulphuric Acid Volumetric Solution, and are used throughout the text without explanation. The factor in each case represents the weight in grammes of the alkaloid required to neutralize 1 Cc. of volumetric acid.

DETERMINATION OF THE OPTICAL ROTATION OF ORGANIC SUBSTANCES.

Many organic substances either liquid by nature or in solution in suitable solvents, when examined in a specially constructed polarizing apparatus or polaristrobometer, exhibit the property of circular polarization, or, in other words, are capable of rotating the plane of polarization of a ray of light either to the right or to the left. Such substances are termed "optically active," and when rotating to the right are designated as "dextro-rotatory" or "dextrogyrate," and when rotating to the left, as "lævo-rotatory" or "lævogyrate." Substances which do not possess this property of optical rotation are termed "optically inactive."

Among the substances recognized by the U. S. Pharmacopœia, there are several, particularly certain essential or volatile oils, and related bodies, for which the determination of the angle of rotation of a ray of polarized light, or, in some cases, the proof of their optical inactivity, affords the most simple and positive evidence of their identity or purity.

The instruments used for this purpose vary somewhat in their construction. Those which are most generally adapted for the examination of the substances mentioned above are the Polaristrobometer of Wild, in which the optical activity of the substance is manifested by the appearance or disappearance of dark, parallel stripes, or the so-called "half-shadow" instrument of Laurent, in which the two sides of the field of vision are capable of becoming unequally illuminated. Both of the instruments permit the angle of rotation to be read off in degrees or fractions of a degree of a circle.

These optical determinations are best made in a dark room, and by means of homogeneous or monochromatic light, the latter being obtained by introducing into a non-luminous flame, on a loop of platinum wire, a small bead of fused sodium chloride. The light thus radiated corresponds with the line D of the solar spectrum.

Since the deviation of the plane of polarization either to the right or to the left of the zero point is directly proportional to the length of the column of liquid, it is important that the observations should be made with tubes of a definite length, such as 100, 50, or 25 Mm. The selection of the length of the tube to be employed is, however, usually dependent upon the depth of color of the liquid and the extent of its optical rotation.

The rotatory power of an optically active, liquid substance, observed with sodium light, and referred to the ideal density 1, and in a tube having a length of 1 decimeter (100 Mm.), is designated as its *specific rotatory power*. This is usually expressed by the term $[a]_D$. Since, however, not only the density of an optically active liquid, but also its rotation, is influenced by the temperature, the specific rotation varies with the latter. In stating the specific rotation it is, therefore, necessary to indicate at what temperature the rotation and the density of the liquid have been determined. But for the same temperature the specific rotation of a pure, optically active liquid is always a constant number. The temperature used in the text of the Pharmacopœia is 25° C. (77° F.).

For calculating the specific rotatory power of an optically active liquid substance, or solution of an optically active solid, the following formulas are of general application:

I. For liquid substances $$[a]_D = \frac{100 \times a}{L \times d}$$

II. For solutions of solids $$[a]_D = \frac{10000 \times a}{L \times p \times d}$$

or $$[a]_D = \frac{10000 \times a}{L \times c}$$

For calculating these formulas the determination of the following factors is necessary:

a = the angle of rotation of the liquid or solid observed with sodium light.

L = the length of the tube in millimeters.

d = the density or specific gravity of the active liquid.

p = the amount of active substance in 100 parts by weight of the solution.

c = the number of grammes of active substance in 100 cubic centimeters of the solution.

List of Abbreviations Used in the Following Table.

abs. = absolute.	dif. = difference.	sp. gr. = specific gravity.
alc. = alcohol.	frac. = fractional.	vol. = volume.
appt. = apparent.	gal. = gallon.	wt. = weight.
cor. = correction.		

Alcohol Table.

Per cent. vol. abs. alc.[1]	Sp. gr. 15.6° C.[2] / 15.6° C.	Dif. of appt. sp. gr. for 1° C.[3]	Frac. per cent.[4]	Vol. in gal. of 100 lbs. av.[5]	Cor. on foregoing for 0.1 per cent.	No. of gal. official alc. in 100 lbs. av.[5]	Cor. on foregoing for 0.1 per cent.	Wt. in lbs. av. of 1 gal. U. S.[6]	Per cent. by wt. abs. alc.	Sp gr. 15.6° C. / 15.6° C.	Cor. of Sp. gr. for 1° C.[7]

[1] Multiply these figures by 1.0535 for the volume per cent. of official alcohol.

[2] Also approximately the weight in kilogrammes of 1 liter of the spirit.

[3] Add if the temperature is above, subtract if below, 15.6° C. (60° F.). If the temperature is taken in Fahrenheit degrees, multiply these figures by 0.555.

[4] Corresponding with a difference in apparent specific gravity of 0.0001.

[5] For the volume in pints of 100 pounds of the spirit multiply these figures by 8; for the volume in fluidounces, multiply by 128; for the volume in liters, multiply by 3.7854. For the volume of 100 ounces avoirdupois in gallons, divide the figures of the table by 16; for the volume in pints, divide by 2; for the volume in fluidounces, multiply by 8. For the volume of 100 grains in fluidounces, multiply by 0.01829; in minims, by 8.777.

[6] For the weight of 1 gallon in ounces avoirdupois, multiply these figures by 16; in grains, by 7000; in grammes, by 453.59. For the weight of 1 pint in pounds, divide these figures by 8; for the weight of 1 pint in ounces, multiply by 2; in grains, multiply by 875. For the weight of 1 fluidounce in ounces avoirdupois, divide these figures by 8; in grains, multiply by 54.69.

EQUIVALENTS OF WEIGHTS AND MEASURES, U. S. P.

CUSTOMARY AND METRIC.

The values given in the following tables for the relation of weight to measure apply to water at its greatest density (temperature 4° C. or 39.2° F.) *in vacuo*, and for ordinary purposes may be used without correction. If intended to be applied to liquids having a higher or lower specific gravity than water, the weight in grammes of such liquid must be divided by the specific gravity of the liquid in order to ascertain the volume in cubic centimeters corresponding to the given weight; the customary fluid measure can then be found by reference to the tables. For instance, to find the volume in fluidounces of 875 grammes of official alcohol, divide 875 by 0.816, which yields 1072.30 cubic centimeters, and 1072.30 Cc. of water at 4° C. equal 36.259 fluidounces, for 1000 : 33.814 : : 1072.30 : x. $x = 36.259$; hence 875 Gm. of alcohol U. S. P. measure practically 36.259 fluidounces.

TABLE SHOWING THE RELATION OF THE DEGREES OF BAUME'S HYDROMETERS TO SPECIFIC GRAVITIES.

The hydrometers most frequently used in the United States are those constructed upon the plan of Baumé. For liquids *heavier* than water the point to which the instrument sinks in pure water is 0, and the point to which it sinks in a solution of 15 parts of dry table-salt in 85 parts of water is marked 15, the distance between the two points being divided into 15 equal parts, and the scale continued with divisions of the same size. For liquids *lighter* than water the instrument is floated in a solution of 10 parts of dry table-salt in 90 parts of water, and afterward in pure water, the distance being divided into 10 equal parts, and the scale continued in like manner; the point indicating the density of water is marked 10. The hydrometers were originally constructed at a *medium* temperature. In the United States they are made for the temperature of 60° F. (15.55° C.), and the scales as originally published by Henry Pemberton (1852) are recognized. They agree closely with the determinations made by Schober and Pescher for liquids heavier than water, and differ but little for liquids lighter than water.

Cartier's hydrometer, which is occasionally employed in France, agrees with Baumé's scale for liquids lighter than water, except that 16° of the latter are equal to 15° Cartier.

For Liquids Heavier than Water.

24 fluidounces wine measure = 25 fluidounces Imperial measure (difference 1 grain).

Approximate Measures.

In Great Britain prescriptions are compounded by weighing the solids and measuring the liquids, and the same course is very generally followed in the United States; but on the continent of Europe weights alone are employed in the making of preparations as well as in the compounding of prescriptions. Medicines are, however, taken by familiar domestic measures, which are subject to considerable variations, but are usually estimated as having the following capacity:

	In the United States.	In France.
A teaspoonful	1 fluidrachm	5 grams of water.
A desertspoonful	2 fluidrachms	10 " " "
A tablespoonful	½ fluidounce	15 " " "
A wineglassful	2 fluidounces	———
A glassful	———	150 grams of water.
A teacupful	4 fluidounces	———
A tumblerful	8 fluidounces	———

The approximate measures by the *handful* (Fr. *poignée*) and pinch (Fr. *pincée*) are almost completely discarded, or employed only for the least active drugs.

The measuring of small quantities of liquids by drops gives very uncertain and variable results, which are influenced by the viscidity of the liquid, the size, shape, and fulness of the vessel, the curvature of the lip, the temperature, the rapidity of dropping, and probably by other circumstances. As a rule, it may be said that aqueous liquids yield larger drops than those containing little or no water; but very different results are obtained with the same liquid dropped from different bottles, or even from the same bottle under different conditions; the differences amount frequently to 50, and occasionally to 200, per cent. For these reasons medicated liquids should not be ordered in drops, but preferably by weight or measure; and whenever it is desirable for the patient to take a medicine by drops, the dose may be approximated by estimating each minim to contain of—

Ether and ethereal solutions	2½ to 3 drops.
Tinctures, alcoholic solutions, and volatile oils	1½ to 2 or 2½ drops.
Medicated wines	1 to 1½ drops.
Water and aqueous solutions	¾ to 1 drop.

In order to avoid to some extent the discrepancies resulting from the dropping of liquids under various conditions, dropping-measures (*compte-gouttes*) have been constructed in France, yielding at 15° C. drops of distilled water, 20 of which weigh 1 Gm.. at least within a limit of 2 per cent. The French Codex gives a table containing the weight of 1 drop, and the number of drops for 1 Gm. of various liquids, dropped under the conditions stated, which may be summarized as follows:

Number of drops	for 1 Gm. of the following liquids:
20	Hydrocyanic acid, Diluted sulphuric acid, Aqueous solutions of the salts of metals and the alkaloids.
21–26	Mineral acids, Ammonia-water, Glycerin, Fowler's solution, Vinegars.
31	Solution of chloral (⅕).
33	Wine (Grenache) and medicated wines.
43	Creasote.
48	Fixed oils.
50–57	Glacial acetic acid, Carbolic acid (alcoholic solution), Alcohol (sp. gr. .864 and over), Chloroform, Volatile oils, Tinctures, Spirit of nitrous ether.
61	Alcohol (sp. gr. .834), Tincture of iodine.
72	Spirit of ether.
90	Ether.

TABLES OF WEIGHTS AND MEASURES.

Apothecaries' or Troy Weight, U. S.

One pound,	℔	= 12 troyounces	= 5760 grains	= 13 ounces avoirdupois	72.5 grains.
One troyounce,	℥	= 8 drachms	= 480 "	= 1 ounce "	42.5 "
One drachm,	ʒ	= 3 scruples	= 60 "		
One scruple,	℈		= 20 "		
One grain,	gr.		= 1 grain.

Weights and Measures of the British Pharmacopœia.

One pound,	℔	= 16 ounces	= 7000 troy grains	= ℔i ℥ij ʒiv gr. xl.
One ounce,	oz.	= 437.5 "	=	℥vij gr. xvijss.
One grain,	gr.	= 1 grain.		

The pound and ounce of the British Pharmacopœia are identical with the same denominations of *avoirdupois weight*. The avoirdupois ounce is subdivided into 16 drachms (1 drachm = 27.34 troy grains); but the British Pharmacopœia recognizes no subdivisions between the ounce and grain. It is, however, optional with the physician *in prescribing* to use the symbols ℈ and ʒ, the former representing 20 and the latter 60 grains, if such be found to conduce to accuracy or convenience.

						Troy grains.	Avoirdupois.

1000 " =	100 " =	10 deciliters =	1.000 "	33.81 "

				Wine measure.
1 liter (or 1 cubic decimeter)				1.0567 quarts.
10 liters =	1 dekaliter			2.6417 gallons.
100 " =	10 dekaliters =	1 hektoliter		26.417 "
1000 " =	100 " =	10 hektoliters =	1 kiloliter or stere	264.17 "

The unit of all metric measures is the *meter* (French, *mètre*), and this is the ten-millionth part of the quadrant or fourth part of the terrestrial meridian, the quadrant being the distance from the equator to the pole. The cube of the tenth part of a meter, denominated *liter* (Fr. *litre*), was adopted as the unit of measures of capacity. The weight of the one-thousandth part of a liter of distilled water at its greatest density (4° C.) was denominated *gram* (Fr. *gramme*), and adopted as the unit of weight. The subdivisions of all measures are named by prefixing to the name of the unit the Latin numerals *deci* (.1), *centi* (.01), and *milli* (.001), and the larger denominations by prefixing the Greek numerals *deka* (10), *hekto* (100), *kilo* (1000), and *myria* (10000).

[1] Or of one gramme in cubic centimeters; strictly true only at 0° C. in vacuo.
[2] Multiply these figures by 2 for weight of one U. S. pint in ounces avoirdupois.
[3] Divide these figures by 2 for volume in pints of 100 ounces avoirdupois.

PHYSIOLOGICAL TESTING.

E. M. Houghton.

Physiological Testing is necessary for the proper determination of the activity of many important drugs which cannot be satisfactorily tested by chemical methods. It is the determination of the change in function "induced in living organisms by the administration in the state of minute division of such unorganized substances as do not act merely as foods," for the purpose of identifying and adjusting the strength of medicinal substances, and may be qualitative or quantitative in kind. It is a well-known fact that the protoplasm of the cells forming the different tissues of the animal body varies in its chemical and physical composition according to the function of the organ in which they are found.

The elective affinity of drugs which enables the physician to increase or decrease the activity of a particular organ in order to combat the pathological effects of disease processes is best explained by assuming that physiological action is the result of some sort of chemical union between the drug and certain constituents of the protoplasm of the cell, and that the greatest change in function will occur in those organs whose protoplasm contains the largest amount of substances which combine with the drug. This view clearly explains why ergot has a specific action on the uterus, as this organ is composed largely of unstriped muscle tissue, and ergot has a special affinity for such muscle tissue wherever found. Cocaine exhibits a special affinity for the protoplasm of the terminations of sensory nerves, while strychnine possesses a similar affinity for the protoplasm of the spinal cord.

The function of an organ is specialized to accomplish some particular purpose and always remains the same in kind, but may be altered in degree.

Those drugs which increase the lability of the protoplasm of the cells augment the specialized function of the organ, and are called stimulants, while other drugs producing the opposite effects, by rendering the protoplasm more stable are termed depressants.

The term irritation is often employed in a loose sense as meaning the same as stimulant. This should be avoided, as it applies more especially to changes produced in protoplasms generally, as changes in growth, nutrition, etc.

Certain drugs, as cocaine, act as depressants to some portions of the animal body and as stimulants to other portions; other drugs, chloral, ether, etc., depress from the beginning of their action, and end in paralyzing directly or indirectly one or all of the organs of the animal body, while still other drugs, strychnine, digitalis, etc., primarily stimulate one or more organs directly or indirectly, but ultimately, if the action is sufficiently prolonged, their terminal effect is depressant, comparable to the effect of fatigue, and finally may end in complete or general paralysis.

As already intimated in the definition, physiological assays may be either qualitative or quantitative. It is not possible in this paper to give minute descriptions of methods for conducting qualitative analysis by pharmacological reactions, as it would be necessary to consider a great number of drugs of therapeutic importance, and besides such a discussion is unnecessary, as the peculiar pharmacological reactions of each drug are mentioned under the heading of physiological action in almost every text-book on the subject of materia medica, which will enable each investigator to apply the usual methods of pharmacological practice to problems as they arise.

The elective affinity of drugs for certain kinds of protoplasm offers in some instances a more certain means of identification than a chemical analysis. The peculiar reaction between digitalin and other heart tonics and the heart muscle brings about, when applied to the laid-bare frog's heart, greatly lessened rhythm and a tendency for the organ to cease beating in the systolic condition. Atropine by paralyzing the terminations of certain peripheral nerve-endings causes the pupil of the eye to dilate in a characteristic manner, while muscarine, acting upon certain other nerve-endings, produces exactly the opposite change in function. Innumerable examples might be given of characteristic

physiological reactions, but these will suffice to show the nature of these reactions. The determination of these special reactions between drugs and protoplasm is just as truly a study in qualitative analysis as an observation of the reaction of drugs to ordinary chemical reagents.

That the reactions between drugs and protoplasm is quantitative in nature has been recognized since the dawn of medicine by the gradual working out of the dosage of each drug. In a study of the quantitative reactions between drugs and protoplasms, by observing the changes in function produced in living animals, the greatest attention must be paid to the details of the experiments. The most important general rules to be observed in order to obtain reliable results are the following:

The reaction chosen as a measure should be the most constant and characteristic obtainable for each given drug.

The kind of animal chosen for making the observation should be the one in which the reaction is most clearly discernible.

The animals employed for making a test should be of the same species, differing as little as possible from one another in weight, temperament, etc., in order that the resistance of the several animals employed for making a test shall be as uniform as possible.

The animals employed for the experiments should be kept under identically the same conditions just before and while the experiments are being made: the same food, the same degree of temperature, etc.

The strength of each preparation in making a quantitative assay should be compared with the strength of a standard preparation, the assay of both being made at the same time, and the conditions of the experiments being precisely the same in both cases.

The standard adopted should possess the pharmacological activity of a preparation representing the activity of an average sample of a first-class drug, as found by taking an average of the strength of several samples of the product, prepared from as many different samples of a drug of first-class quality, as determined by botanical or chemical methods; each sample being prepared according to the same formula.

The action of the drug being assayed should, if possible, be compared with the action of the standard upon the same animal, and, in those cases where it cannot be done, a sufficient number of animals of uniform resistance should be employed to rule out any individual idiosyncrasy.

An outline of the methods devised and employed by the author for some of the most important medicinal preparations, which are not amenable to chemical assay, may be given as follows:

ERGOT.

For centuries it has been observed that fowls, swine, and other animals, as well as man, feeding upon ergotized rye, develop sooner or later gangrene and sloughing of peripheral parts, as the combs and wattles of fowls, ears of swine, etc. This reaction is so constant, especially upon fowls, that it has been found a reliable indication of the presence of the active constituents of ergot, desired for therapeutic purposes, in the various pharmaceutical preparations of the drug (Kobert, Houghton, Jacobi, etc.).

While the chemistry of ergot is not clearly worked out, it is generally believed that the cornutin and sphacelinic acid contained in ergot are the active principles which produce the desired therapeutic action.

Extensive experiments have shown that a preparation of ergot that produces blackening of the the cock's comb, when given in suitable doses, will likewise produce abortion in pregnant animals. An investigation by the writer covering several years has shown that the blackening produced in the rooster's comb varies in intensity and rapidity of development in proportion to the quantity of the drug administered and the rapidity of absorption. Considerable difficulty is encountered in determining the reaction, owing to the variability in the resistance of individual fowls, as found in the market, but by careful breeding of thoroughbred chickens and great attention to methods of feeding, conditions under which the fowls are kept, etc., and by comparing the reaction obtained by the administration of a certain quantity of the ergot, or preparation of ergot, with the reaction produced by the feeding of a given quantity of the standard preparation, reliable results are obtained.

HEART TONICS.

Pharmacologists generally are agreed that the active constituents (which are probably all glucosides) of the various heart tonics—digitalis, strophanthus, etc.—possess the same general physiological action upon the factors concerned in the maintenance of the circulation of the blood, differing mainly in degree. The most important phenomena observable in animals and man when under the influence of these drugs are the slowing and strengthening of the heart-beats and an increase in blood-pressure.

Two series of experiments will show in a characteristic manner the qualitative reaction, viz., the application of a solution of the drug to the laid-bare frog's heart, which is followed by gradual slowing of heart-beats and a tendency for the organ to dilate less and less until it finally ceases to beat, and remains in the systolic condition; and the intravenous or subcutaneous injection of solutions of the drugs into dogs, rabbits, or other animals, which produce a characteristic increase in blood-pressure and slowing of the heart. These reactions are best shown by graphic tracings recorded by the kymograph.

A quantitative assay is more difficult, Several methods have been tried, but the method proposed for the assay of strophanthus (Houghton, *Jour. Amer. Med. Assoc.*, 1899), slightly modified for the other members of the group (digitalis, convallaria majalis, squill, etc.), has been extensively employed, and gives quite accurate results. This method is based upon the fact that the killing power of the heart tonics for frogs of definite size and species, kept under proper conditions, is constant per gramme of body-weight. The frogs employed for making a test should be of the same size and species, but since it is practically impossible to obtain upon the market frogs of exactly the same size, it is best to sort the frogs into several groups according to size, using one size for one particular drug, another size for another, etc. Frogs weighing 12 to 30 grammes are large enough, and can usually be obtained at a very reasonable price.

The application of the method may be briefly described as follows:

Apparatus.—Small wire frog baskets with legs and covers, or frog glasses and plates, will do, care being taken not to set the baskets too deeply in water and not to fill the plates sufficiently full of water to drown the animals. The water should cover the bottom of the baskets or plates about one-fourth inch.

Small balance for weighing the frogs.

Volumetric flasks for diluting the preparations to be assayed, and glass pipettes, graduated into hundredths of a cubic centimeter, with long narrow points, or supplied with needle-points, for injecting the frogs.

The strength of the preparation being assayed is to be compared with the strength of a standard preparation of the drug, the two being tested at the same time and under the same conditions. An illustration will best show how this is done, as, for example, tincture of strophanthus.

A standard preparation is obtained according to the method outlined in the general remarks, which is of the strength of an average sample of tincture strophanthus prepared from first-class strophanthus Kombé seeds.

One Cc. of the tincture to be assayed is measured out and diluted with normal saline solution, to make the dilution such that the amount to be injected into each frog shall be about 0.5 Cc., the same care being exercised in making the solution as would be exercised in making up volumetric solutions for chemical assays.

The frogs which are of the same species and have been kept under the same conditions are weighed out, and the weights recorded, the frogs being marked so that they can be readily identified. The frogs should not differ more than 3 grammes in weight, but may be of any size, the aim being to have the resistance uniform. It will be necessary to inject several series of frogs on as many different days, approximately as follows:

First Series:

A. *Frogs Injected with Standard.*

Number of Frogs.	Weight of Frogs.	Amount of Tincture Injected per Gm. body-weight.	Result at End of 12 hours.
1	15 Gm.	0.0001	Alive.
2	16 "	0.00015	"
3	15 "	0.0002	Dead.
4	17 "	0.00025	"

The killing dose is between 0.00015 and 0.0002.

B. *Frogs Injected with Tincture to be Assayed.*

Number of Frogs.	Weight of Frogs.	Amount of Tincture Injected per Gm. body-weight.	Result at End of 12 hours.
1	16 Gm.	0.0001	Alive.
2	15 "	0.00015	"
3	17 "	0.0002	"
4	15 "	0.00025	Dead.

The killing dose is between 0.0002 and 0.00025.

Second Series:

A. *Standard.*

Number of Frogs.	Weight of Frogs.	Amount of Tincture Injected per Gm. body-weight.	Result at End of 12 hours.
1	15 Gm.	0.00015	Alive.
2	16 "	0.00016	Dead.
3	15 "	0.00017	"
4	17 "	0.00018	"
5	16 "	0.00019	"

The killing dose is between 0.00015 and 0.00016.

B. *Tincture being Assayed.*

Number of Frogs.	Weight of Frogs.	Amount of Tincture Injected per Gm. body-weight.	Result at End of 12 hours.
1	16 Gm.	0.0002	Alive.
2	17 "	0.00021	"
3	15 "	0.00022	Dead.
4	16 "	0.00023	"
5	17 "	0.00024	"

The killing dose is between 0.00021 and 0.00022.

Third Series:

A. *Standard.*

Number of Frogs.	Weight of Frogs.	Amount of Tincture Injected per Gm. body-weight.	Result at End of 12 hours.
1	15 Gm.	0.00016	Alive.
2	16 "	0.00016	Dead.
3	16 "	0.00016	"
4	17 "	0.00016	"
5	16 "	0.00016	Alive.

Minimum fatal dose, 0.00016.

B. *Tincture being Assayed.*

Number of Frogs.	Weight of Frogs.	Amount of Tincture Injected per Gm. body-weight.	Result at End of 12 hours.
1	16 Gm.	0.00022	Dead.
2	17 "	0.00022	"
3	15 "	0.00022	Alive.
4	16 "	0.00022	"
5	17 "	0.00022	Dead.

Minimum fatal dose, 0.00022.

According to the results obtained from the injection of the three series of frogs, 0.00016 Cc. of the standard tincture (a tincture of 100 per cent.) has the same killing power as 0.00022 Cc. of the tincture being assayed. Hence, the tincture possesses a strength of $\frac{0.00016}{0.00022} = \frac{16}{22} = 72+\%$ of standard.

INDIAN CANNABIS.

No drug in the entire Pharmacopœia has been found more frequently to produce variable therapeutic results than Indian Cannabis.

An examination of the effects on dogs and other animals by the internal administration of a large number of samples of crude Indian Cannabis and its pharmaceutical preparations showed conclusively that when the drug was active it produced a characteristic intoxication varying in degree with the quantity and activity of the drug, rapidity of absorption, individual susceptibility of the animal, etc.

Practical application of this reaction (Houghton), for the purpose of testing preparations of Indian Cannabis, by feeding them in suitable doses to dogs, and comparing the effects produced with the intoxication resulting from known doses of preparations of definite strength, has proved of much value, as is evidenced by the uniformly favorable reports of physicians employing preparations of the drug so tested.

SUPRARENAL GLANDS.

Seldom in the history of medicine has a substance so quickly demonstrated for itself a place in therapeutics as the preparations of the suprarenal glands and their active constituent, Adrenalin; but so readily is this active principle decomposed that no satisfactory method of chemical assay has been devised for it, hence the need of a pharmacological method.

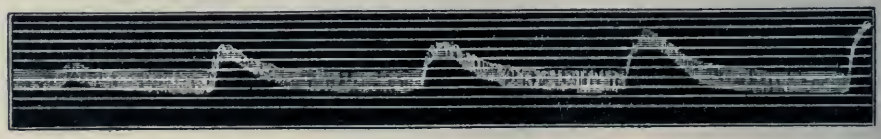
The following method (Houghton, *Jour. Amer. Med. Assoc.*) was devised as the result of extended study of the chemical and pharmacological properties of the active principle (Adrenalin), and the various preparations obtained from these glands has given quite satisfactory results.

The application of this method depends upon the fact that intravenous injections of Adrenalin, or preparations containing Adrenalin, produce a transitory rise in blood-pressure, such increase in blood-pressure, within certain limits, varying according to the amount of the active principle injected.

The standard with which a given preparation is compared is a 1 : 1000 freshly made solution of chemically pure Adrenalin. Hypodermic syringes, pipettes, surgical instruments of various kinds, glass cannulæ, and a large-sized kymograph, with manometer arranged for making blood-pressure tracings on smoked paper, etc., are required. Everything needed will usually be found in a well-equipped pharmacological laboratory.

Various animals may be employed, but dogs of medium size give the best results. Whatever animal is employed, it is carefully anesthetized, preferably with chloretone given per os. Chloretone is much better for experiments of this kind, as its action is long continued, and it has little or no effect upon the circulatory system. After the animal becomes completely unconscious he is fastened in the dorsal position to a holder, the hair is clipped from the throat and groin, and glass cannulæ of suitable size are tied into the carotid artery and femoral vein. The cannula tied in the carotid artery is connected in turn with an inelastic tube, filled with a half-saturated solution of sodium carbonate or other solution to prevent the blood from clotting, leading to the manometer of the kymograph. The drum of the kymograph is set in motion, the clamp removed from the carotid, and a tracing made, showing the normal height of the blood pressure. The smoked paper should have linear rulings, for convenience in reading results, one-half a centimeter apart. Two kinds of tracings may be obtained, complete ones, several sheets of paper being used if necessary, where the drum is kept in constant motion; or abbreviated ones where the drum remains at rest during each reaction, recording only the maximum blood-pressure, which are more convenient for practical purposes (see tracings Nos. 1 and 2).

When a tracing showing the normal blood-pressure has been taken, a definite quantity of the diluted 1 : 1000 solution of Adrenalin, properly diluted with physiological



No. 1.—Complete tracing, showing variations in the blood-pressure from the intravenous injection of different amounts of adrenalin.

saline solution, is slowly injected into the femoral vein; within a few moments the blood-pressure rapidly rises (possibly several centimeters) and as quickly subsides to the normal. Allowing a few minutes' rest to the animal, an injection of a small portion of the preparation which is being assayed is made, care being taken to remove as far as possible inert substances from the preparation for injection. Care must also be taken that the

quantity of fluid and time required in making the injection be the same as that of the standard. Repeated injections of the same amount of fluid, but containing a varying quantity of the active principle, are made of the preparation being assayed until the rise in blood-pressure produced by the unknown is equal to the rise in blood-pressure

No. 2.—Abbreviated blood-pressure tracing, showing the comparative action of two solutions of adrenalin. The solutions were of exactly the same strength, but the person making the assay supposed they were of different strengths until he had proven by experiment that they had the same influence on blood-pressure.

produced by a definite quantity of the 1 : 1000 adrenalin. The quantity of the preparation injected must always be less than sufficient to produce the maximum rise in blood-pressure. Observation of the effects produced by different quantities of the preparation will show whether the maximum effect has been produced. Suppose that one finds that the same effect on the blood-pressure is produced by 1 Cc. of standard 1 : 1000 solution of Adrenalin and 1 Cc. of the preparation being assayed, diluted 1 : 1200, then the strength of the preparation being assayed equals $\frac{1000}{1200} = \frac{5}{6} = 83+$ per cent.

BOTANICAL NAMES.

A failure to employ accurately the botanical names of plants is responsible for many failures in the investigation of, and errors in recording, the properties of drugs. The meaning of names recognized in the Pharmacopœia is accurately defined and firmly established, but usage of names of unofficial drugs is lamentably loose, and the correct uses of the botanical names is the only certain safeguard against error.

Each plant has two names: one indicates the genus or group to which it belongs, and corresponds to a person's family name, as *Acer*, the maples, and *Salix*, the willows. The other indicates the species and corresponds to the Christian name of a person, as, in Salix *alba*, the White willow, and *nigra*, the Black willow. The two names applied together to a plant, as *Salix nigra*, or *S. alba*, comprise the binomial. In writing successively several binomials pertaining to the same genus, it is customary to abbreviate to the first letter the generic name in all except the first binomial, as in the last two names given above.

Each of these names was given to its genus or species, respectively, by some botanist, who is thus known as the author of the genus or species. It has frequently happened that another botanist has subsequently assigned the same name in a different application, so that the meaning is uncertain unless the author's name be subjoined to the plant name or binomial; thus, *Electra* DC. and *Electra* Panzer, or *Acer saccharinum* L. and *A. saccharinum* Wang. The author's name and the plant name are printed in different type, or in Ms. one is underlined. Writing the name of the author in parentheses indicates that he is not the author of the binomial, but of the species-name only, which he improperly connected with some other genus; as *Calotropis gigantea* (L.), which Linné had called "*Asclepias gigantea*." If another author's name follows the parenthesis, as *Calotropis gigantea* (L.) Dryander, it indicates that the second-named author (Dryander) referred the species to its proper genus and is the author of the binomial. When no other author's name follows the parenthesis it indicates that no one has previously referred the name to its proper genus, and that the author of the article is then doing so.

Occasionally a trinomial is used, thus, "*Polygonatum multiflorum pubescens*" Wood, indicating a peculiar form of the species, but not a distinct species.

GENERAL INDEX.

A

Aaron's rod, 471
Abedul, 299
Abele, 1347
Abelmoschus, 946
Abeloura, 529
Abführender Thee, 1429
Abführendes Brawsepulver, 1266
Abführpillen, 1189
Abiennic acid, 1521
Abies Abies, 1205
  balsamea, 1198, 1521
  Canadensis, 1197
  cedrus, 1337
  larix, 1197, 1520
  mariana, 1521
  nigra, 1521
  sibirica, 1034
  species of, 1521
    oil of, 1014
Abietene, 1520
Abietic acid, 1306
  anhydride. 1306
Abietolic acid, 1521
Abkochungen, 524
Abohna, 508
Abohrinha do mato, 508
Abraham's balm, 1631
Abrasol, 934
Abrastol, 298, 343
Abrin, 2
Abroma, 947
Abrotano, 4
Abrus, 1, 733
Absinthe grande, 2
Absinthic acid, 3
Absinthiin, 3
Absinthis, 2
Absinthium, 2
  officinale, 2
  oil of, 3
Absinthol, 3
Absolute alcohol, 124
Absoluter Alkohol, 124
Abuta, 963, 1147
Abutilon, 947
Abutua, 1147
Acacia, 4, 385, 856
  bark, varieties of, 1282
  catechu, 708
  false, 867
  mucilage of, 986
  Senegal, 4
  species of, 5, 6, 7
Acacine, 7
Acæna, 1325
Acafrao, 502
Acajou à pommes, 174
Acalypha Indica, 587
Acanthaceæ, 7
Acanthomastic, 957
Acanthosicyos, 508
Acanthus family, 7
  ilicifolia, 8
Acaroid resin, 1648
Acaroides resin, 1648
Acebo, 805
Acedera, 1332
Aceite de ajonjoli, 1106
  de cacao, 1112
  de grano tiglio, 1115
  de higado de bacalao, 1086
  de olivas, 1091
  de palma, 1095
  de ricino, 1097
  de sassafras, 862
Acerdilla, 1333
Acetaldehyde, 1146
Acet-amido-ethyl-salicylic acid, 13
Acet-Phénétidine, 11
Acetanilide, 8
  ammoniated, 9
  powder, compound, 1264
Acetanilidum, 8
Acetate, ammonium, and iron, solution of, 897
    solution of, 886
  amyl, 129, 168
  barium, 280
  calcium, 343
  chinoidine, 404
  chromium, 418
  copper, 513
  ethyl, 113
  ferric, solution of, 894
  lead, 1209
  magnesium, solution of, 907
  mercuric, 784
  of morphina, 981
    solution of, 907
  of potash, 1221
  potassium, 1221
  quinine, 1288
  silver, 237
  of soda, 1390
  sodio-theobromine, 1391
  zinc, 1651
Acétate basique de cuivre, 514
  ferrique liquide, 894
  d'albumine, 146
  d'ammoniaque liquide, 886
  de baryum, 280
  de chaux, 343
  de cuivre, 513
  d'éthyle, 113
  de magnésie, 942
  de morphine, 981
  de plomb, 1209
  de potasse, 1221
  de soude, 1390
  de zinc, 1651
Acetato de soda, 1390
  de zinc, 1651
Acetbromanilide, 9
Acetic acid, 27, 30
    diluted, 30
    glacial, 31
    and turpentine, liniment of, 883
  aldehyde, 1146
  ether, 113
  extract of colchicum, 596
Acetic—
  fermentation, 123
  turpentine liniment, 883
Aceto, 14
Aceto-ortho-amido-quinoline, 1299
Acétolé de scille, 18
Acètomel, 1132
Aceton, 10
Acétone, 10, 1206
Acétone-diéthylsulfone, 1473
Acetonum, 10
Acetophenone, 11
Acetopyrine, 194
Acetosa, 1332
Acetoscillitico, 18
Acetosella vulgaris, 1332
Acetozone, 222
Acetpara-amidosalol, 1165
Acet-phenetidine, 1158
Acetphenetidinum, 11, 1158
Acetum, 14
  antisepticum, 16
  aromaticum, 16

    rectificatum, 16
  saturni, 909
  scillæ, 18
  scilliticum, 18
Acetylamidobenzene, 8
Acetylen, 18
Acetylene, 18
Acetylenum, 18
Acetylethoxyphenylurethane, 117
Acetyloxyphenylurethane, 117
Acetylpara-amidophenol salicylate, 1165
Acetysalicylic acid, 77
Ache celeri, 1593
  de Montague, 874
  des chiens, 483
Achillea, 475
  ptarmica, 182
  species of, oils of, 1031
Achilletine, 476
Achiote, 242
Achiotillo, 242
Achras, 751
Achroodextrin, 527
Achyranthes, 148
Acibar, 134
Acid or acids, 19
  abiennic, 1521
  abietic, 1306
  abietinolic, 1521
  abietolic, 1521
  absinthic, 3
  acet-amido-ethyl-salicylic, 13
  acetic, 27, 30

Acid-
acetic, diluted, 30
glacial, 31
and turpentine, liniment of, 383
acetylsalicylic, 77
aconitic, 24, 42, 99, 105, 759
acrylic, 540
æscinic, 762
æsculetinic, 762
agaric, 32, 120
agaricic, 32, 120
aldehydodimethylprotocatechuic, 26
amidoacetic, 616
amido-caproic, 570
amido-formic, 25
amido-succinamic, 140
amido-succinic, 25
amygdalic, 163, 1260
anacardic, 174
anchusic, 313
angelic, 24, 176
anhydro-orthosulphamide-benzoic, 293
anisic, 24
anthemic, 959
anthranilic, 809
antirrhinic, 1375
apiolic, 1593
apoglucinic, 762
apophyllic, 1123
arabic, 6
arachic, 25
arachidic, 25
aristidionic, 1384
aristinic, 1384
aristolic, 1384
arsenic, 21
arsenous, 243
solution of, 250, 885
artanthic, 958
aspartic, 25, 260
aurantiamaric, 269
auric, 272
benzamidoacetic, 25
benzenedicarboxylic, 26
benzoic, 32, 292
boheic, 1524
boracic, 35
boric, 35
borocitric, 37
borophenylic, 37
borosalicylic, 37
β-Oxynapthyl-o-oxy-m-toluyic, 298
butyric, 25, 762
cacodylic, 21
caffeanic, 327
caffeelic, 327
caffeic, 25, 327
caffeo-tannic, 327
cahincic, 1329
callitrolic, 1350
calumbic, 346
cambogic, 353
camphor mixture, 355
camphoric, 37, 355
camphoronic, 38, 355
camphresinic, 355
canadinolic, 1521
canadolic, 1521
cantharidic, 361
capric, 25
carbamic, 25
carbazotic, 74
carbolic. *See* Phenol.
crude, 1161
liquefied, 1163
carbonic, 38
carminic, 453

Acid—
carthamic, 373
caryophyllinic, 376
casein, 378
catechinic, 386
catechutannic, 386, 708
cathartic, 1318, 1381
cerotic, 25
cetraric, 398
cevadic, 1336
chaulmoogric, 753
chelidonic, 1628
chiococcaic, 1329
chlorogenic, 327
cholic, 616
chromic. *See* Chromii Trioxidum.
solution of, 886
chrysatropic, 1427
chrysominic, 1316
chrysophanic, 40, 419, 1318, 1381
